

DATA SHEET

UBA2033 HF full bridge driver IC

Product specification

2002 Oct 08

HF full bridge driver IC**UBA2033****FEATURES**

- Full bridge driver circuit
- Integrated bootstrap diodes
- Integrated high voltage level shift function
- High voltage input for the internal supply voltage
- 550 V maximum voltage
- Bridge disable function
- Input for start-up delay
- Adjustable oscillator frequency
- Predefined bridge position during start-up.

GENERAL DESCRIPTION

The UBA2033 is a high voltage monolithic integrated circuit made in the EZ-HV SOI process. The circuit is designed for driving the MOSFETs in a full bridge configuration. In addition, it features a disable function, an internal adjustable oscillator and an external drive function with a low-voltage level shifter for driving the bridge. To guarantee an accurate 50% duty factor, the oscillator signal can be passed through a divider before being fed to the output driver.

APPLICATIONS

- The UBA2033 can drive (via the MOSFETs) any kind of load in a full bridge configuration
- The circuit is especially designed as a commutator for High Intensity Discharge (HID) lamps.

UBA2033

FUNCTIONAL DESCRIPTION

Supply voltage

The UBA2033 is powered by a supply voltage applied to pin HV, for instance the supply voltage of the full bridge. The IC generates its own low supply voltage for the internal circuitry. Therefore an additional low voltage supply is not required. A capacitor has to be connected to pin V_{DD} to obtain a ripple-free internal supply voltage.

The circuit can also be powered by a low voltage supply directly applied to pin V_{DD}. In this case pin HV should be connected to pin V_{DD} or SGND.

Start-up

With an increasing supply voltage the IC enters the start-up state; the higher power transistors are kept off and the lower power transistors are switched on. During the start-up state the bootstrap capacitors are charged and the bridge output current is zero. The start-up state is defined until V_{DD} = V_{DD(UVLO)}, where UVLO stands for Under Voltage Lock-out. The state of the outputs during the start-up phase is overruled by the bridge disable function.

Release of the power drive

At the moment the supply voltage on pin V_{DD} or HV exceeds the level of release power drive, the output voltage of the bridge depends on the control signal on pin EXTDR (see Table 1). The bridge position after start-up, disable, or delayed start-up (via pin SU) depends on the status of the pins DD and EXTDR. If pin DD = LOW (divider enabled) the bridge will start in the pre-defined position: pin GLR and pin GHL = HIGH and pin GLL and pin GHR = LOW. If pin DD = HIGH (divider disabled) the bridge position will depend on the status of pin EXTDR.

If the supply voltage on pin V_{DD} or HV decreases and drops below the reset level of power drive the IC enters the start-up state again.

Oscillation

At the point where the supply voltage on pin HV crosses the level of release power drive, the bridge begins commutating between the following two defined states:

- Higher left and lower right MOSFETs on, higher right and lower left MOSFETs off
- Higher left and lower right MOSFETs off, higher right and lower left MOSFETs on.

The oscillation can take place in three different modes:

- Internal oscillator mode.

In this mode the bridge commutating frequency is determined by the values of an external resistor (R_{osc}) and capacitor (C_{osc}). In this mode pin EXTDR must be connected to pin +LVS. To realize an accurate 50% duty factor, the internal divider should be used. The internal divider is enabled by connecting pin DD to SGND. Due to the presence of the divider the bridge frequency is half the oscillator frequency. The commutation of the bridge will take place at the falling edge of the signal on pin RC. To minimize the current consumption pins +LVS, -LVS and EXTDR can be connected together to either pin SGND or V_{DD}. In this way the current source in the logic voltage supply circuit is shut off.

- External oscillator mode without the internal divider.

In the external oscillator mode the external source is connected to pin EXTDR and pin RC is short-circuited to pin SGND to disable the internal oscillator. If the internal divider is disabled (pin DD = V_{DD}) the duty factor of the bridge output signal is determined by the external oscillator signal and the bridge frequency equals the external oscillator frequency.

- External oscillator mode with the internal divider.

The external oscillator mode can also be used with the internal divider function enabled (pin RC and pin DD = SGND). Due to the presence of the divider the bridge frequency is half the external oscillator frequency. The commutation of the bridge is triggered by the falling edge of the EXTDR signal with respect to V_{-LVS}.

The design equation for the bridge oscillator frequency is:

$$f_{\text{bridge}} = \frac{1}{(k_{\text{osc}} \times R_{\text{osc}} \times C_{\text{osc}})}$$

Non-overlap time

The non-overlap time is the time between turning off the conducting pair of MOSFETs and turning on the next pair. The non-overlap time is internally fixed to a very small value, which allows an HID system to operate with a very small phase difference between load current and full bridge voltage (pins SHL and SHR). Especially when igniting an HID lamp via a LC resonance circuit, a small 'dead time' is essential. The high maximum operating frequency, together with a small 'dead time', also gives the opportunity to ignite the HID lamp at the third harmonic of the full bridge voltage, thereby reducing costs in the magnetic power components.

HF full bridge driver IC

UBA2033

'Dead time' can be increased by adding a resistor (for slowly turning on the full bridge power FETs) and a diode (for quickly turning off the full bridge power FETs) in parallel, both in series with the gate drivers (see Fig.3).

Divider function

If pin DD = SGND, then the divider function is enabled/present. If the divider function is present there is no direct relation between the position of the bridge output and the status of pin EXTDR.

Start-up delay

Normally, the circuit starts oscillating as soon as pin V_{DD} or HV reaches the level of release power drive. At this

moment the gate drive voltage is equal to the voltage on pin V_{DD} for the low side transistors and $V_{DD} - 0.6$ V for the high side transistors. If this voltage is too low for sufficient drive of the MOSFETs the release of the power drive can be delayed via pin SU.

A simple RC filter (R between pins V_{DD} and SU; C between pins SU and SGND) can be used to make a delay, or a control signal from a processor can be used.

Bridge disable

The bridge disable function can be used to switch off all the MOSFETs as soon as the voltage on pin BD exceeds the bridge disable voltage (1.29 V). The bridge disable function overrules all the other states.

Table 1 Logic table; note 1

DEVICE STATUS	INPUTS				OUTPUTS			
	BD	SU	DD	EXTDR	GHL	GHR	GLL	GLR
Start-up state	HIGH	X	X	X	LOW	LOW	LOW	LOW
	LOW	X	X	X	LOW	LOW	HIGH	HIGH
Oscillation state	HIGH	X	X	X	LOW	LOW	LOW	LOW
	LOW	LOW	X	X	LOW	LOW	HIGH	HIGH

k_{osc}	oscillator constant	$f_{\text{bridge}} = 250\text{ Hz}$	0.94	1.02	1.10	
R_{ext}	external resistor to V_{DD}		100	–	–	$\text{k}\Omega$

Notes

1. The current is specified without commutation of the bridge. The current into pin HV is limited by a thermal protection circuit. The current is limited to 11 mA at $T_j = 150\text{ }^{\circ}\text{C}$.
2. The current is specified without commutation of the bridge and pin HV is connected to V_{DD} .
3. The minimum frequency is mainly determined by the value of the bootstrap capacitors.

HF full bridge driver IC

UBA2033

APPLICATION INFORMATION

Basic application

A basic full bridge configuration with an HID lamp is shown in Fig.3. The bridge disable, the start-up delay and the external drive functions are not used in this application. The pins -LVS, +LVS, EXTDR and BD are short-circuited to SGND. The internal oscillator is used and to realize a 50% duty cycle the internal divider function has to be used

by connecting pin DD to SGND. The IC is powered by the high voltage supply. Because the internal oscillator is used, the bridge commutating frequency is determined by the values of R_{OSC} and C_{OSC} . The bridge starts oscillating when the HV supply voltage exceeds the level of release power drive (typically 12.5 V on pin HV). If the supply voltage on pin HV drops below the reset level of power drive (typically 10 V on pin HV), the UBA2033 enters the start-up state.

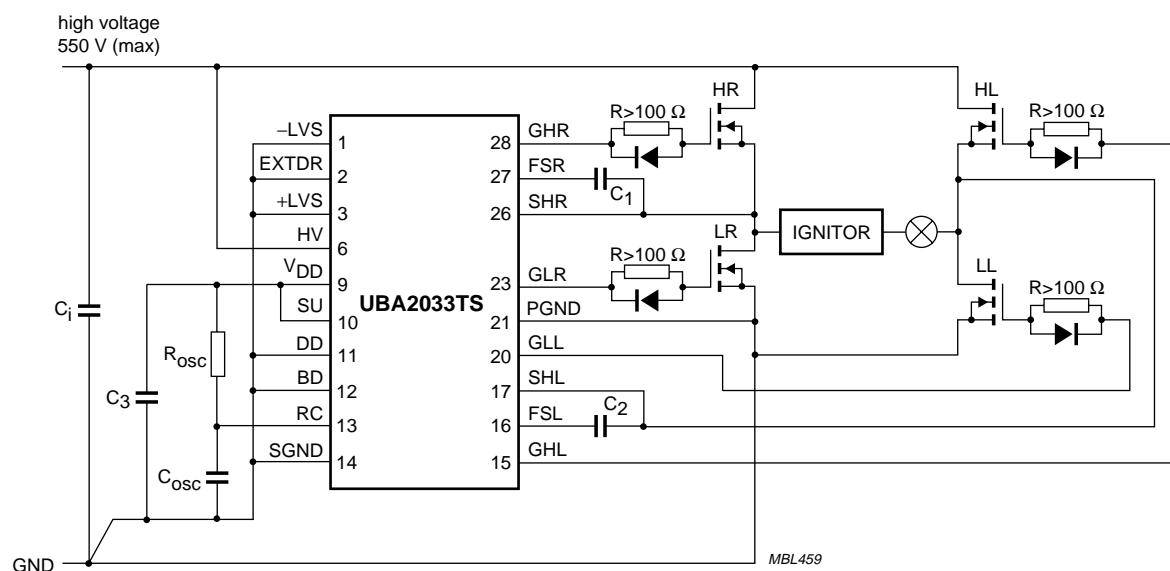

Fig.3 Basic configuration.

HF full bridge driver IC

UBA2033

Application with external control

Figure 4 shows an application containing a system ground-referenced control circuit. Pin +LVS can be connected to the same supply as the external oscillator control unit and pin –LVS is connected to SGND. Pin RC is

short-circuited to SGND. The bridge commutation frequency is determined by the external oscillator. The bridge disable input (pin BD) can be used to immediately turn off all four MOSFETs in the full bridge.

HF full bridge driver ICUBA2033

Additional application information**GATE RESISTORS**

At ignition of an HID lamp, a large EMC spark occurs. This can result in a large voltage transient or oscillation at the gates of the full bridge MOSFETs (LL, LR, HR and HL). When these gates are directly coupled to the gate drivers (pins GHR, GLR, GHL and GLL), voltage overstress of the driver outputs may occur. Therefore it is advised to add a resistor with a minimum value of 100 Ω in series with each gate driver to isolate the gate driver outputs from the actual power MOSFETs gate.

'Dead time' can also be adjusted via the combination gate resistor and gate-source capacitance.

GATE CHARGE AND SUPPLY CURRENT AT HIGH FREQUENCY USE

The total gate current needed to charge the gates of the power MOSFETs equals:

$$I_{\text{gate}} = 4 \times f_{\text{bridge}} \times Q_{\text{gate}}$$

Where:

I_{gate} = gate current

f_{bridge} = bridge frequency

Q_{gate} = gate charge.

This current is supplied via the internal low voltage supply (V_{DD}). Since this current is limited to 11 mA (see "Characteristics" table note 1), at higher frequencies and with MOSFETs having a relative high gate charge, this maximum V_{DD} supply current may not be sufficient anymore. As a result the internal low voltage supply (V_{DD}) and the gate drive voltage will drop resulting in an increase of the higher resistance (R_{on}) of the full bridge MOSFETs. In this case an auxiliary low voltage supply is necessary.

SOLDERING

Introduction to soldering surface mount packages

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"Data Handbook IC26; Integrated Circuit Packages"* (document order number 9398 652 90011).

There is no soldering method that is ideal for all surface mount IC packages. Wave soldering can still be used for certain surface mount ICs, but it is not suitable for fine pitch SMDs. In these situations reflow soldering is recommended.

Reflow soldering

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several methods exist for reflowing; for example, convection or convection/infrared heating in a conveyor type oven. Throughput times (preheating, soldering and cooling) vary between 100 and 200 seconds depending on heating method.

Typical reflow peak temperatures range from 215 to 250 °C. The top-surface temperature of the packages should preferably be kept below 220 °C for thick/large packages, and below 235 °C for small/thin packages.

Wave soldering

Conventional single wave soldering is not recommended for surface mount devices (SMDs) or printed-circuit boards with a high component density, as solder bridging and non-wetting can present major problems.

To overcome these problems the double-wave soldering method was specifically developed.

If wave soldering is used the following conditions must be observed for optimal results:

- Use a double-wave soldering method comprising a turbulent wave with high upward pressure followed by a smooth laminar wave.
- For packages with leads on two sides and a pitch (e):
 - larger than or equal to 1.27 mm, the footprint longitudinal axis is **preferred** to be parallel to the transport direction of the printed-circuit board;
 - smaller than 1.27 mm, the footprint longitudinal axis **must** be parallel to the transport direction of the printed-circuit board.

The footprint must incorporate solder thieves at the downstream end.

- For packages with leads on four sides, the footprint must be placed at a 45° angle to the transport direction of the printed-circuit board. The footprint must incorporate solder thieves downstream and at the side corners.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Manual soldering

Fix the component by first soldering two diagonally-opposite end leads. Use a low voltage (24 V or less) soldering iron applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C.

When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

HF full bridge driver IC

UBA2033

Suitability of surface mount IC packages for wave and reflow soldering methods

PACKAGE	SOLDERING METHOD	
	WAVE	REFLOW ⁽¹⁾
BGA, HBGA, LFBGA, SQFP, TFBGA	not suitable	suitable
HBCC, HLQFP, HSQFP, HSOP, HTQFP, HTSSOP, HVQFN, SMS	not suitable ⁽²⁾	suitable
PLCC ⁽³⁾ , SO, SOJ	suitable	suitable
LQFP, QFP, TQFP	not recommended ⁽³⁾⁽⁴⁾	suitable
SSOP, TSSOP, VSO	not recommended ⁽⁵⁾	suitable

Notes

1. All surface mount (SMD) packages are moisture sensitive. Depending upon the moisture content, the maximum temperature (with respect to time) and body size of the package, there is a risk that internal or external package cracks may occur due to vaporization of the moisture in them (the so called popcorn effect). For details, refer to the Drypack information in the *"Data Handbook IC26; Integrated Circuit Packages; Section: Packing Methods"*.
2. These packages are not suitable for wave soldering. On versions with the heatsink on the bottom side, the solder cannot penetrate between the printed-circuit board and the heatsink. On versions with the heatsink on the top side, the solder might be deposited on the heatsink surface.
3. If wave soldering is considered, then the package must be placed at a 45° angle to the solder wave direction. The package footprint must incorporate solder thieves downstream and at the side corners.
4. Wave soldering is only suitable for LQFP, TQFP and QFP packages with a pitch (e) equal to or larger than 0.8 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.65 mm.
5. Wave soldering is only suitable for SSOP and TSSOP packages with a pitch (e) equal to or larger than 0.65 mm; it is definitely not suitable for packages with a pitch (e) equal to or smaller than 0.5 mm.

1. Please consult the most recently issued data sheet before initiating or completing a design.
2. The product status of the device(s) described in this data sheet may have changed since this data sheet was published. The latest information is available on the Internet at URL <http://www.semiconductors.philips.com>.
3. For data sheets describing multiple type numbers, the highest-level product status determines the data sheet status.

DEFINITIONS

Short-form specification — The data in a short-form specification is extracted from a full data sheet with the same type number and title. For detailed information see the relevant data sheet or data handbook.

Limiting values definition — Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 60134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

Application information — Applications that are described herein for any of these products are for illustrative purposes only. Philips Semiconductors make no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

DISCLAIMERS

Life support applications — These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips Semiconductors customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips Semiconductors for any damages resulting from such application.

Right to make changes — Philips Semiconductors reserves the right to make changes in the products - including circuits, standard cells, and/or software - described or contained herein in order to improve design and/or performance. When the product is in full production (status 'Production'), relevant changes will be communicated via a Customer Product/Process Change Notification (CPCN). Philips Semiconductors assumes no responsibility or liability for the use of any of these products, conveys no licence or title under any patent, copyright, or mask work right to these products, and makes no representations or warranties that these products are free from patent, copyright, or mask work right infringement, unless otherwise specified.
