**Optional Data Transmit Format: Automatic Increment Mode**

In this transmission method, data is set on automatically incremented sub-address from the specified sub-address.

	typ.	8.8	9.0	9.0	
	max	9.1	9.3	9.3	

Note 1: Please see the following Figure.

Note, however, that the conditions apply only to the case where the device is mounted on board A (180 mm × 125 mm × 1.6 mm, one-sided); board B (329 mm × 249 mm × 1.6 mm, two-sided); or board C (276 mm × 192 mm × 1.6 mm, six-layered). When mounting the IC, select boards no smaller than these. When using under the conditions of board A, set the IC's power supply voltage (pins 19, 40, 55) to 8.8 V (±0.3 V) Because the IC's thermal capacity margin is narrow, when designing a set, incorporate heat discharge features into the design. Note that the power dissipation varies widely depending on the board mounting conditions.

**Figure 1 Characteristics of decrease in power dissipation**

Note 2: Pins 3, 4, 5, 7, 8, 9, 10, 11, 20, 21, 22, 23, 30, 31, 33, 34, 36, 39, 45, 46, 49, 50, 51, 52 and 53 are susceptible to damage from surge voltages and should thus be handled with extreme care.

Note 3: Power supply sequence

At power-on, power should be supplied to the IC's power supply pins according to the following sequence: first to pin 29 ( $I^2L V_{DD}$ ), then to pin 19 (DEF/DAC  $V_{CC}$ ), and finally to pin 40/pin 55 (RGB  $V_{CC}/YC V_{CC}$ ). Power to pin 29 should be supplied from pin 19 via zener diode through resistor.

If power is not supplied to all the power pins or if power is not supplied in the above sequence, BUS preset will be unsettled and the IC may not function properly.

Especially, when the frequency of H-out (pin 26) will be unsettled, H deflection output transistor may be broken.

When this IC will be used on CRT, the frequency of H-out should be controlled by pin 22.

**Figure (Note 3) Timing from immediately after power-on to time at which H-out is output (at  $T_a = 25^\circ\text{C}$ )**

Note 4:  $V_{CC}$  condition at Power-OFF

At power-off, the last pulse of H-out (pin 26) will become unknown, if  $I^2L V_{DD}$  (pin 29) is over 1.7 V at the timing of H-out stop.

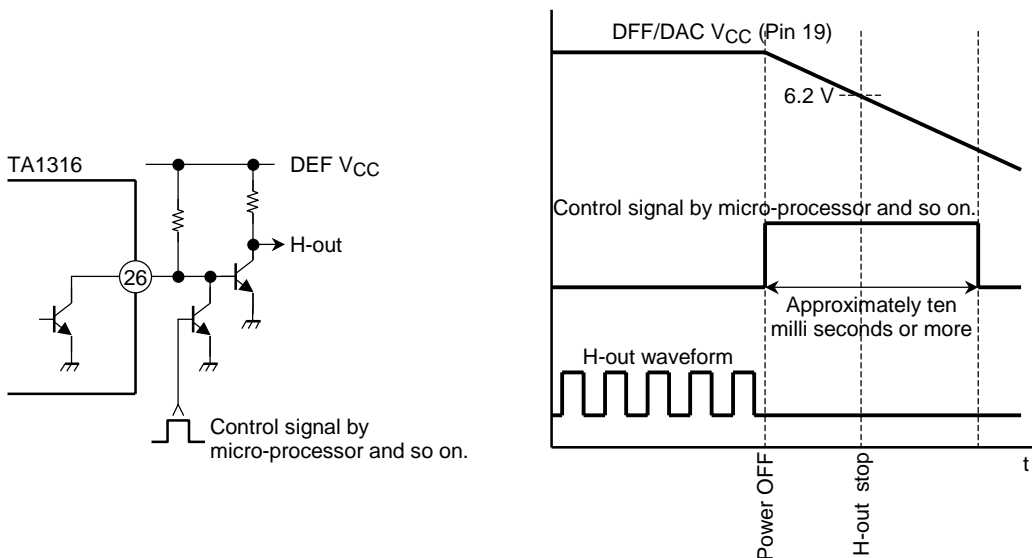

$I^2L V_{DD}$  should be below 1.7 V when DEF/DAC  $V_{CC}$  (pin 19) will be 6.2 V, which is the maximum voltage when H-out stops.

Refer to Figure (Note 4-1).

**Figure (Note 4-1)  $V_{CC}$  condition at power-off**

If it is not in the condition of Figure (Note 4-1), it is recommended that H-out will be made LOW at power-off by external control like micro-processor and so on. Refer to Figure (Note 4-2).

**Figure (Note 4-2) Example how to stop H-out**
