3-Pin Microprocessor Reset Monitors

Features

- Precision V_{CC} Monitor for 3.0V, 3.3V, and 5.0V Supplies
- 140msec Guaranteed Minimum $\overline{\text{RESET}}$, RESET Output Duration
- $\overline{\text{RESET}}$ Output Guaranteed to V_{CC} = 1.0V (MAX809)
- Low 17µA Supply Current
- V_{CC} Transient Immunity
- Small SOT–23 Package
- No External Components
- Wide Operating Temperature: –40°C to 85°C

Typical Applications

- Computers
- Embedded Systems
- Battery Powered Equipment
- Critical µP Power Supply Monitoring

The MAX809 and MAX810 are cost–effective system supervisor circuits designed to monitor V_{CC} in digital systems and provide a reset signal to the host processor when necessary. No external components are required.

The reset output is driven active within 20 µsec of V_{CC} falling through the reset voltage threshold. Reset is maintained active for a minimum of 140msec after V_{CC} rises above the reset threshold. The MAX810 has an active–high RESET output while the MAX809 has an active–low $\overline{\text{RESET}}$ output. The output of the MAX809 is guaranteed valid down to V_{CC} = 1V. Both devices are available in a SOT–23 package.

The MAX809/810 are optimized to reject fast transient glitches on the V_{CC} line. Low supply current of 17µA (V_{CC} = 3.3V) makes these devices suitable for battery powered applications.

PIN DESCRIPTION

Pin No.	Symbol	Description
1	GND	Ground
2	$\overline{\text{RESET}}$ (MAX809)	$\overline{\text{RESET}}$ output remains low while V_{CC} is below the reset voltage threshold, and for 240msec (typ.) after V_{CC} rises above reset threshold
2	RESET (MAX810)	RESET output remains high while V_{CC} is below the reset voltage threshold, and for 240msec (typ.) after V_{CC} rises above reset threshold
3	V_{CC}	Supply Voltage (typ.)

APPLICATIONS INFORMATION

V_{CC} Transient Rejection

The MAX809/810 provides accurate V_{CC} monitoring and reset timing during power–up, power–down, and brownout/sag conditions, and rejects negative–going transients (glitches) on the power supply line. Figure 1 shows the maximum transient duration vs. maximum negative excursion (overdrive) for glitch rejection. Any combination of duration and overdrive which lies **under** the curve will **not** generate a reset signal. Combinations above the curve are detected as a brownout or power–down. Transient immunity can be improved by adding a capacitor in close proximity to the V_{CC} pin of the MAX809/810.

$\overline{\text{RESET}}$ Signal Integrity During Power–Down

The MAX809 $\overline{\text{RESET}}$ output is valid to V_{CC} = 1.0V. Below this voltage the output becomes an "open circuit" and does not sink current. This means CMOS logic inputs to the µP will be floating at an undetermined voltage. Most digital systems are completely shutdown well above this voltage. However, in situations where $\overline{\text{RESET}}$ must be maintained valid to V_{CC} = 0V, a pull–down resistor must be connected from $\overline{\text{RESET}}$ to ground to discharge stray capacitances and hold the output low (Figure 2). This resistor value, though not critical, should be chosen such that it does not appreciably load $\overline{\text{RESET}}$ under normal operation (100kΩ will be suitable for most applications). Similarly, a pull–up resistor to V_{CC} is required for the MAX810 to ensure a valid high $\overline{\text{RESET}}$ for V_{CC} below 1.0V.

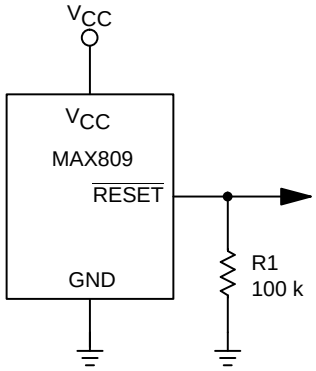

Figure 2. Ensuring RESET Valid to V_{CC} = 0 V

Processors With Bidirectional I/O Pins

Some µP's (such as Motorola 68HC11) have bi–directional reset pins. Depending on the current drive capability of the processor pin, an indeterminate logic level may result if there is a logic conflict. This can be avoided by adding a 4.7kΩ resistor in series with the output of the MAX809/810 (Figure 3). If there are other components in the system which require a reset signal, they should be buffered so as not to load the reset line. If the other components are required to follow the reset I/O of the µP, the buffer should be connected as shown with the solid line.
