# M29DW640D

64 Mbit (8Mb x8 or 4Mb x16, Multiple Bank, Page, Boot Block) 3V Supply Flash Memory

PRELIMINARY DATA

FEATURES SUMMARY

- SUPPLY VOLTAGE
  - V_{CC} = 2.7V to 3.6V for Program, Erase and Read
  - V_{PP} =12V for Fast Program (optional)
- ASYNCHRONOUS PAGE READ MODE
  - Page Width 4 Words
  - Page Access 25, 30ns
  - Random Access 70, 90ns
- PROGRAMMING TIME
  - 10µs per Byte/Word typical
  - 4 Words / 8 Bytes at-a-time Program
- MEMORY BLOCKS
  - Quadruple Bank Memory Array: 8Mbit+24Mbit+24Mbit+8Mbit
  - Parameter Blocks (at both Top and Bottom)
- DUAL OPERATIONS
  - While Program or Erase in a group of banks (from 1 to 3), Read in any of the other banks
- PROGRAM/ ERASE SUSPEND and RESUME MODES
  - Read from any Block during Program Suspend
  - Read and Program another Block during Erase Suspend
- UNLOCK BYPASS PROGRAM COMMAND
  - Faster Production/Batch Programming
- $V_{PP}/\overline{WP}$ PIN for FAST PROGRAM and WRITE PROTECT
- TEMPORARY BLOCK UNPROTECTION MODE
- COMMON FLASH INTERFACE
  - 64 bit Security Code
- EXTENDED MEMORY BLOCK
  - Extra block used as security block or to store additional information

Figure 1. Packages

TSOP48 (N)
12 x 20mm

TFBGA63 (ZA)
7 x 11mm
- LOW POWER CONSUMPTION
  - Standby and Automatic Standby
- 100,000 PROGRAM/ERASE CYCLES per BLOCK
- ELECTRONIC SIGNATURE
  - Manufacturer Code: 0020h
  - Device Code: 227Eh + 2202h + 2201h

TABLE OF CONTENTS

SUMMARY DESCRIPTION

The M29DW640D is a 64 Mbit (8Mb x8 or 4Mb x16) non-volatile memory that can be read, erased and reprogrammed. These operations can be performed using a single low voltage (2.7 to 3.6V) supply. On power-up the memory defaults to its Read mode where it can be read in the same way as a ROM or EPROM.

The device features an asymmetrical block architecture, with 16 parameter and 126 main blocks, divided into four Banks, A, B, C and D, providing multiple Bank operations. While programming or erasing is underway in one group of banks (from 1 to 3), reading can be conducted in any of the other banks. The bank architecture is summarized in Table 2. Eight of the Parameter Blocks are at the top of the memory address space, and eight are at the bottom.

M29DW640D has one extra 256 Byte block (Extended Block) that can be accessed using a dedicated command. The Extended Block can be protected and so is useful for storing security information. However the protection is irreversible, once protected the protection cannot be undone.

Each block can be erased independently, so it is possible to preserve valid data while old data is erased. The blocks can be protected to prevent accidental Program or Erase commands from modifying the memory. Program and Erase commands are written to the Command Interface of the memory. An on-chip Program/Erase Controller simplifies the process of programming or erasing the memory by taking care of all of the special operations that are required to update the memory contents. The end of a program or erase operation can be detected and any error conditions identified. The command set required to control the memory is consistent with JEDEC standards.

Chip Enable, Output Enable and Write Enable signals control the bus operation of the memory. They allow simple connection to most microprocessors, often without additional logic.

The memory is offered in TSOP48 (12x20mm) and TFBGA63 (7x11mm, 0.8mm pitch) packages. The memory is supplied with all the bits erased (set to '1').

Note: Also see Appendix A, Table 22 for a full listing of the Block Addresses.

SIGNAL DESCRIPTIONS

See Figure 2, Logic Diagram, and Table 1, Signal Names, for a brief overview of the signals connected to this device.

Address Inputs (A0-A21). The Address Inputs select the cells in the memory array to access during Bus Read operations. During Bus Write operations they control the commands sent to the Command Interface of the internal state machine.

Data Inputs/Outputs (DQ0-DQ7). The Data I/O outputs the data stored at the selected address during a Bus Read operation. During Bus Write operations they represent the commands sent to the Command Interface of the internal state machine.

Data Inputs/Outputs (DQ8-DQ14). The Data I/O outputs the data stored at the selected address during a Bus Read operation when $\overline{BYTE}$ is High, V_{IH}. When $\overline{BYTE}$ is Low, V_{IL}, these pins are not used and are high impedance. During Bus Write operations the Command Register does not use these bits. When reading the Status Register these bits should be ignored.

Data Input/Output or Address Input (DQ15A–1). When $\overline{BYTE}$ is High, V_{IH}, this pin behaves as a Data Input/Output pin (as DQ8-DQ14). When $\overline{BYTE}$ is Low, V_{IL}, this pin behaves as an address pin; DQ15A–1 Low will select the LSB of the addressed Word, DQ15A–1 High will select the MSB. Throughout the text consider references to the Data Input/Output to include this pin when $\overline{BYTE}$ is High and references to the Address Inputs to include this pin when $\overline{BYTE}$ is Low except when stated explicitly otherwise.

Chip Enable ($\overline{E}$). The Chip Enable, $\overline{E}$, activates the memory, allowing Bus Read and Bus Write operations to be performed. When Chip Enable is High, V_{IH}, all other pins are ignored.

Output Enable ($\overline{G}$). The Output Enable, $\overline{G}$, controls the Bus Read operation of the memory.

Write Enable ($\overline{W}$). The Write Enable, $\overline{W}$, controls the Bus Write operation of the memory's Command Interface.

V$_{PP}$/Write Protect (V$_{PP}$/$\overline{WP}$). The V$_{PP}$/Write Protect pin provides two functions. The V$_{PP}$ function allows the memory to use an external high voltage power supply to reduce the time required for Program operations. This is achieved by bypassing the unlock cycles and/or using the multiple Word (2 or 4 at-a-time) or multiple Byte Program (2, 4 or 8 at-a-time) commands. The Write Protect function provides a hardware method of protecting the four outermost boot blocks (two at the top, and two at the bottom of the address space).

When V$_{PP}$/Write Protect is Low, V_{IL}, the memory protects the four outermost boot blocks; Program and Erase operations in these blocks are ignored while V$_{PP}$/Write Protect is Low, even when $\overline{RP}$ is at V_{ID}.

When V$_{PP}$/Write Protect is High, V_{IH}, the memory reverts to the previous protection status of the four outermost boot blocks (two at the top, and two at the bottom of the address space). Program and Erase operations can now modify the data in these blocks unless the blocks are protected using Block Protection.

When V$_{PP}$/Write Protect is raised to V$_{PP}$ the memory automatically enters the Unlock Bypass mode. When V$_{PP}$/Write Protect returns to V_{IH} or V_{IL} normal operation resumes. During Unlock Bypass Program operations the memory draws I$_{PP}$ from the pin to supply the programming circuits. See the description of the Unlock Bypass command in the Command Interface section. The transitions from V_{IH} to V$_{PP}$ and from V$_{PP}$ to V_{IH} must be slower than t_{VHVPP}, see Figure 16.

Never raise V$_{PP}$/Write Protect to V$_{PP}$ from any mode except Read mode, otherwise the memory may be left in an indeterminate state.

The V$_{PP}$/Write Protect pin must not be left floating or unconnected or the device may become unreliable. A 0.1µF capacitor should be connected between the V$_{PP}$/Write Protect pin and the V$_{SS}$ Ground pin to decouple the current surges from the power supply. The PCB track widths must be sufficient to carry the currents required during Unlock Bypass Program, I$_{PP}$.

Reset/Block Temporary Unprotect ($\overline{RP}$). The Reset/Block Temporary Unprotect pin can be used to apply a Hardware Reset to the memory or to temporarily unprotect all Blocks that have been protected.

Note that if V$_{PP}$/$\overline{WP}$ is at V_{IL}, then the four outermost boot blocks will remain protected even if RP is at V_{ID}.

A Hardware Reset is achieved by holding Reset/Block Temporary Unprotect Low, V_{IL}, for at least t_{PLPX}. After Reset/Block Temporary Unprotect goes High, V_{IH}, the memory will be ready for Bus Read and Bus Write operations after t_{PHEL} or t_{RHEL}, whichever occurs last. See the Ready/Busy Output section, Table 18 and Figure 15, Reset/Temporary Unprotect AC Characteristics for more details.

Holding $\overline{RP}$ at V_{ID} will temporarily unprotect the protected Blocks in the memory. Program and Erase operations on all blocks will be possible. The transition from V_{IH} to V_{ID} must be slower than t_{PHPHH}.

Ready/Busy Output (R$\overline{\text{B}}$). The Ready/Busy pin is an open-drain output that can be used to identify when the device is performing a Program or Erase operation. During Program or Erase operations Ready/Busy is Low, V_{OL}. Ready/Busy is high-impedance during Read mode, Auto Select mode and Erase Suspend mode.

After a Hardware Reset, Bus Read and Bus Write operations cannot begin until Ready/Busy becomes high-impedance. See Table 18 and Figure 15, Reset/Temporary Unprotect AC Characteristics.

The use of an open-drain output allows the Ready/Busy pins from several memories to be connected to a single pull-up resistor. A Low will then indicate that one, or more, of the memories is busy.

Byte/Word Organization Select ($\overline{\text{BYTE}}$). The Byte/Word Organization Select pin is used to switch between the x8 and x16 Bus modes of the memory. When Byte/Word Organization Select is Low, V_{IL}, the memory is in x8 mode, when it is High, V_{IH}, the memory is in x16 mode.

V_{CC} Supply Voltage (2.7V to 3.6V). V_{CC} provides the power supply for all operations (Read, Program and Erase).

The Command Interface is disabled when the V_{CC} Supply Voltage is less than the Lockout Voltage, V_{LKO}. This prevents Bus Write operations from accidentally damaging the data during power up, power down and power surges. If the Program/Erase Controller is programming or erasing during this time then the operation aborts and the memory contents being altered will be invalid.

A 0.1µF capacitor should be connected between the V_{CC} Supply Voltage pin and the V_{SS} Ground pin to decouple the current surges from the power supply. The PCB track widths must be sufficient to carry the currents required during Program and Erase operations, I_{CC3}.

V_{SS} Ground. V_{SS} is the reference for all voltage measurements. The device features two V_{SS} pins both of which must be connected to the system ground.

BUS OPERATIONS

There are five standard bus operations that control the device. These are Bus Read (Random and Page modes), Bus Write, Output Disable, Standby and Automatic Standby.

Using the multiple bank architecture of the M29DW640D, while programming or erasing is underway in one group of banks (from 1 to 3), reading can be conducted in any of the other banks. Write operations are only allowed in one bank at a time.

See Tables 3 and 4, Bus Operations, for a summary. Typically glitches of less than 5ns on Chip Enable, Write Enable, and Reset pins are ignored by the memory and do not affect bus operations.

Bus Read. Bus Read operations read from the memory cells, or specific registers in the Command Interface. To speed up the read operation the memory array can be read in Page mode where data is internally read and stored in a page buffer. The Page has a size of 4 Words and is addressed by the address inputs A0-A1.

A valid Bus Read operation involves setting the desired address on the Address Inputs, applying a Low signal, V_{IL}, to Chip Enable and Output Enable and keeping Write Enable High, V_{IH}. The Data Inputs/Outputs will output the value, see Figure 11, Random Read AC Waveforms, Figure 11, Page Read AC Waveforms and Table 15, Read AC Characteristics, for details of when the output becomes valid.

Bus Write. Bus Write operations write to the Command Interface. A valid Bus Write operation begins by setting the desired address on the Address Inputs. The Address Inputs are latched by the Command Interface on the falling edge of Chip Enable or Write Enable, whichever occurs last. The Data Inputs/Outputs are latched by the Command Interface on the rising edge of Chip Enable or Write Enable, whichever occurs first. Output Enable must remain High, V_{IH}, during the whole Bus Write operation. See Figures 13 and 14, Write AC Waveforms, and Tables 16 and 17, Write AC Characteristics, for details of the timing requirements.

Output Disable. The Data Inputs/Outputs are in the high impedance state when Output Enable is High, V_{IH}.

Standby. When Chip Enable is High, V_{IH}, the memory enters Standby mode and the Data Inputs/Outputs pins are placed in the high-impedance state. To reduce the Supply Current to the Standby Supply Current, I_{CC2}, Chip Enable should be held within $V_{CC} \pm 0.2V$. For the Standby current level see Table 14, DC Characteristics.

During program or erase operations the memory will continue to use the Program/Erase Supply Current, I_{CC3}, for Program or Erase operations until the operation completes.

Automatic Standby. If CMOS levels ($V_{CC} \pm 0.2V$) are used to drive the bus and the bus is inactive for 300ns or more the memory enters Automatic Standby where the internal Supply Current is reduced to the Standby Supply Current, I_{CC2}. The Data Inputs/Outputs will still output data if a Bus Read operation is in progress.

Special Bus Operations

Additional bus operations can be performed to read the Electronic Signature and also to apply and remove Block Protection. These bus operations are intended for use by programming equipment and are not usually used in applications. They require V_{ID} to be applied to some pins.

Electronic Signature. The memory has two codes, the manufacturer code and the device code, that can be read to identify the memory. These codes can be read by applying the signals listed in Tables 3 and 4, Bus Operations.

Block Protect and Chip Unprotect. Groups of blocks can be protected against accidental Program or Erase. The Protection Groups are shown in Appendix A, Table 22, Block Addresses. The whole chip can be unprotected to allow the data inside the blocks to be changed.

The V_{PP}/Write Protect pin can be used to protect the four outermost boot blocks. When V_{PP}/Write Protect is at V_{IL} the four outermost boot blocks are protected and remain protected regardless of the Block Protection Status or the Reset/Block Temporary Unprotect pin status.

Block Protect and Chip Unprotect operations are described in Appendix D.

Table 3. Bus Operations, $\overline{\text{BYTE}}$ = V$_{IL}$

Operation	$\overline{\text{E}}$	$\overline{\text{G}}$	$\overline{\text{W}}$	Address Inputs						Data Inputs/Outputs	
				A21-A12	A3	A2	A1	A0	others, DQ15A-1	DQ14-DQ8	DQ7-DQ0
Bus Read	V$_{IL}$	V$_{IL}$	V$_{IH}$	Cell Address						Hi-Z	Data Output

Note: X = V$_{IL}$ or V$_{IH}$.

COMMAND INTERFACE

All Bus Write operations to the memory are interpreted by the Command Interface. Commands consist of one or more sequential Bus Write operations. Failure to observe a valid sequence of Bus Write operations will result in the memory returning to Read mode. The long command sequences are imposed to maximize data security.

The address used for the commands changes depending on whether the memory is in 16-bit or 8-bit mode. See either Table 5, or 6, depending on the configuration that is being used, for a summary of the commands.

Read/Reset Command

The Read/Reset command returns the memory to its Read mode where it behaves like a ROM or EPROM. It also resets the errors in the Status Register. Either one or three Bus Write operations can be used to issue the Read/Reset command.

The Read/Reset command can be issued, between Bus Write cycles before the start of a program or erase operation, to return the device to read mode. If the Read/Reset command is issued during the timeout of a Block erase operation then the memory will take up to 10μs to abort. During the abort period no valid data can be read from the memory. The Read/Reset command will not abort an Erase operation when issued while in Erase Suspend.

Auto Select Command

The Auto Select command is used to read the Manufacturer Code, the Device Code and the Block Protection Status and the Extended block indicator. It can be addressed to either Bank. Three consecutive Bus Write operations are required to issue the Auto Select command. The final Write cycle must be addressed to one of the Banks. Once the Auto Select command is issued Bus Read operations to the Bank where the command was issued output the Auto Select data. Bus Read operations to the other Bank will output the contents of the memory array. The memory remains in Auto Select mode until a Read/Reset or CFI Query command is issued. This command must be issued addressing the same Bank, as was given when entering Autoselect Mode.

In Auto Select mode the Manufacturer Code can be read using a read operation, A6 and A3 to A0 each held at V_{IL}, and A21-A12 set to the Bank Address. The other address bits may be set to either V_{IL} or V_{IH}.

The Device Codes can be read using a read operation, A6 held at V_{IL}, A3 to A0 each held at the levels given in Tables 3 and 4, and A21-A12 set to the Bank Address. The other address bits may be set to either V_{IL} or V_{IH}.

The Block Protection Status of each block can be read using a read operation, A6 A3 A2 A0 each held at V_{IL}, A1 held at V_{IH}, and A21-A19 set to the Bank Address, and A18-A12 specifying the address of the block inside the Bank. The other address bits may be set to either V_{IL} or V_{IH}. If the addressed block is protected then 01h is output on Data Inputs/Outputs DQ0-DQ7, otherwise 00h is output.

The Extended Block Status of the Extended Block can be read using a read operation, A6, A3 and A2, at V_{IL}, A0 and A1, at V_{IH}, and A21-A19 set to Bank Address A. The other bits may be set to either V_{IL} or V_{IH} (Don't Care). If the Extended Block is "Factory Locked" then 80h is output on Data Input/Outputs DQ0-DQ7, otherwise 00h is output.

Read CFI Query Command

The Read CFI Query Command is used to put the addressed bank in Read CFI Query mode. Once in Read CFI Query mode Bus Read operations to the same bank will output data from the Common Flash Interface (CFI) Memory Area. If the read operations are to a different bank from the one specified in the command then the read operations will output the contents of the memory array and not the CFI data.

One Bus Write cycle is required to issue the Read CFI Query Command. Care must be taken to issue the command to one of the banks (A21-A14) along with the address shown in Tables 3 and 4 (A-1, A0-A10). Once the command is issued subsequent Bus Read operations in the same bank (A21-A14) to the addresses shown in Appendix B (A13-A0), will read from the Common Flash Interface Memory Area.

This command is valid only when the device is in the Read Array or Autoselected mode. To enter Read CFI query mode from Autoselect mode, the Read CFI Query command must be issued to the same bank address as the Autoselect command, otherwise the device will not enter Read CFI Query mode.

The Read/Reset command must be issued to return the device to the previous mode (the Read Array mode or Autoselected mode). A second Read/Reset command would be needed if the device is to be put in the Read Array mode from Autoselected mode.

See Appendix B, Tables 23, 24, 25, 26, 27 and 28 for details on the information contained in the Common Flash Interface (CFI) memory area.

Program Command

The Program command can be used to program a value to one address in the memory array at a time. The command requires four Bus Write operations, the final Write operation latches the ad-

dress and data in the internal state machine and starts the Program/Erase Controller.

Programming can be suspended and then resumed by issuing a Program Suspend command and a Program Resume command, respectively (see Program Suspend Command and Program Resume Command paragraphs).

If the address falls in a protected block then the Program command is ignored, the data remains unchanged. The Status Register is never read and no error condition is given.

After programming has started, Bus Read operations in the Bank being programmed output the Status Register content, while Bus Read operations to the other Bank output the contents of the memory array. See the section on the Status Register for more details. Typical program times are given in Table 7.

After the program operation has completed the memory will return to the Read mode, unless an error has occurred. When an error occurs Bus Read operations to the Bank where the command was issued will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.

Note that the Program command cannot change a bit set at '0' back to '1'. One of the Erase Commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

Fast Program Commands

There are five Fast Program commands available to improve the programming throughput, by writing several adjacent Words or Bytes in parallel.

Double Word Program Command. This is used to write two adjacent Words in x16 mode, in parallel. The addresses of the two Words must differ only in A0.

Three bus write cycles are necessary to issue the command.

- The first bus cycle sets up the command.
- The second bus cycle latches the Address and the Data of the first Word to be written.
- The third bus cycle latches the Address and the Data of the second Word to be written and starts the Program/Erase Controller.

Quadruple Word Program Command. This is used to write a page of four adjacent Words, in x16 mode, in parallel. The addresses of the four Words must differ only in A1 and A0.

Five bus write cycles are necessary to issue the command.

- The first bus cycle sets up the command.
- The second bus cycle latches the Address and the Data of the first Word to be written.

- The third bus cycle latches the Address and the Data of the second Word to be written.
- The fourth bus cycle latches the Address and the Data of the third Word to be written.
- The fifth bus cycle latches the Address and the Data of the fourth Word to be written and starts the Program/Erase Controller.

Double Byte Program Command. This is used to write two adjacent Bytes in x8 mode, in parallel. The addresses of the two Bytes must differ only in DQ15A-1.

Three bus write cycles are necessary to issue the command.

- The first bus cycle sets up the command.
- The second bus cycle latches the Address and the Data of the first Byte to be written.
- The third bus cycle latches the Address and the Data of the second Byte to be written and starts the Program/Erase Controller.

Quadruple Byte Program Command. This is used to write four adjacent Bytes in x8 mode, in parallel. The addresses of the four Bytes must differ only in A0, DQ15A-1.

Five bus write cycles are necessary to issue the command.

- The first bus cycle sets up the command.
- The second bus cycle latches the Address and the Data of the first Byte to be written.
- The third bus cycle latches the Address and the Data of the second Byte to be written.
- The fourth bus cycle latches the Address and the Data of the third Byte to be written.
- The fifth bus cycle latches the Address and the Data of the fourth Byte to be written and starts the Program/Erase Controller.

Octuple Byte Program Command. This is used to write eight adjacent Bytes, in x8 mode, in parallel. The addresses of the eight Bytes must differ only in A1, A0 and DQ15A-1.

Nine bus write cycles are necessary to issue the command.

- The first bus cycle sets up the command.
- The second bus cycle latches the Address and the Data of the first Byte to be written.
- The third bus cycle latches the Address and the Data of the second Byte to be written.
- The fourth bus cycle latches the Address and the Data of the third Byte to be written.
- The fifth bus cycle latches the Address and the Data of the fourth Byte to be written.
- The sixth bus cycle latches the Address and the Data of the fifth Byte to be written.

- The seventh bus cycle latches the Address and the Data of the sixth Byte to be written.
- The eighth bus cycle latches the Address and the Data of the seventh Byte to be written.
- The ninth bus cycle latches the Address and the Data of the eighth Byte to be written and starts the Program/Erase Controller.

Only one bank can be programmed at any one time. The other bank must be in Read mode or Erase Suspend.

Fast programming should not be attempted when V$_{PP}$ is not at V$_{PPH}$.

After programming has started, Bus Read operations in the Bank being programmed output the Status Register content, while Bus Read operations to the other Bank output the contents of the memory array.

Programming can be suspended and then resumed by issuing a Program Suspend command and a Program Resume command, respectively. (See Program Suspend Command and Program Resume Command paragraphs.)

After the program operation has completed the memory will return to the Read mode, unless an error has occurred. When an error occurs Bus Read operations to the Bank where the command was issued will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.

Note that the Fast Program commands cannot change a bit set at '0' back to '1'. One of the Erase Commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

Typical Program times are given in Table 7, Program, Erase Times and Program/Erase Endurance Cycles.

Unlock Bypass Command

The Unlock Bypass command is used in conjunction with the Unlock Bypass Program command to program the memory faster than with the standard program commands. When the cycle time to the device is long (as with some EPROM programmers) considerable time saving can be made by using these commands. Three Bus Write operations are required to issue the Unlock Bypass command.

Once the Unlock Bypass command has been issued the bank enters Unlock Bypass mode. The Unlock Bypass Program command can then be issued to program addresses within the bank, or the Unlock Bypass Reset command can be issued to return the bank to Read mode. In Unlock Bypass mode the memory can be read as if in Read mode.

When V$_{PP}$ is applied to the V$_{PP}$/Write Protect pin the memory automatically enters the Unlock By-

pass mode and the Unlock Bypass Program command can be issued immediately.

Unlock Bypass Program Command

The Unlock Bypass Program command can be used to program one address in the memory array at a time. The command requires two Bus Write operations, the final write operation latches the address and data in the internal state machine and starts the Program/Erase Controller.

The Program operation using the Unlock Bypass Program command behaves identically to the Program operation using the Program command. The operation cannot be aborted, a Bus Read operation to the Bank where the command was issued outputs the Status Register. See the Program command for details on the behavior.

Unlock Bypass Reset Command

The Unlock Bypass Reset command can be used to return to Read/Reset mode from Unlock Bypass Mode. Two Bus Write operations are required to issue the Unlock Bypass Reset command. Read/Reset command does not exit from Unlock Bypass Mode.

Chip Erase Command

The Chip Erase command can be used to erase the entire chip. Six Bus Write operations are required to issue the Chip Erase Command and start the Program/Erase Controller.

If any blocks are protected then these are ignored and all the other blocks are erased. If all of the blocks are protected the Chip Erase operation appears to start but will terminate within about 100μs, leaving the data unchanged. No error condition is given when protected blocks are ignored.

During the erase operation the memory will ignore all commands, including the Erase Suspend command. It is not possible to issue any command to abort the operation. Typical chip erase times are given in Table 7. All Bus Read operations during the Chip Erase operation will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the Chip Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs the memory will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read Mode.

The Chip Erase Command sets all of the bits in unprotected blocks of the memory to '1'. All previous data is lost.

Block Erase Command

The Block Erase command can be used to erase a list of one or more blocks in one or more Banks. It sets all of the bits in the unprotected selected

![ST logo]

blocks to '1'. All previous data in the selected blocks is lost.

Six Bus Write operations are required to select the first block in the list. Each additional block in the list can be selected by repeating the sixth Bus Write operation using the address of the additional block. The Block Erase operation starts the Program/Erase Controller after a time-out period of 50µs after the last Bus Write operation. Once the Program/Erase Controller starts it is not possible to select any more blocks. Each additional block must therefore be selected within 50µs of the last block. The 50µs timer restarts when an additional block is selected. After the sixth Bus Write operation a Bus Read operation within the same Bank will output the Status Register. See the Status Register section for details on how to identify if the Program/Erase Controller has started the Block Erase operation.

If any selected blocks are protected then these are ignored and all the other selected blocks are erased. If all of the selected blocks are protected the Block Erase operation appears to start but will terminate within about 100µs, leaving the data unchanged. No error condition is given when protected blocks are ignored.

During the Block Erase operation the memory will ignore all commands except the Erase Suspend command and the Read/Reset command which is only accepted during the 50µs time-out period. Typical block erase times are given in Table 7.

After the Erase operation has started all Bus Read operations to the Banks being erased will output the Status Register on the Data Inputs/Outputs. See the section on the Status Register for more details.

After the Block Erase operation has completed the memory will return to the Read Mode, unless an error has occurred. When an error occurs Bus Read operations to the Banks where the command was issued will continue to output the Status Register. A Read/Reset command must be issued to reset the error condition and return to Read mode.

Erase Suspend Command

The Erase Suspend command may be used to temporarily suspend a Block or multiple Block Erase operation. One Bus Write operation specifying the Bank Address of one of the Blocks being erased is required to issue the command. Issuing the Erase Suspend command returns the whole device to Read mode.

The Program/Erase Controller will suspend within the Erase Suspend Latency time (see Table 7 for value) of the Erase Suspend Command being issued. Once the Program/Erase Controller has stopped the memory will be set to Read mode and

the Erase will be suspended. If the Erase Suspend command is issued during the period when the memory is waiting for an additional block (before the Program/Erase Controller starts) then the Erase is suspended immediately and will start immediately when the Erase Resume Command is issued. It is not possible to select any further blocks to erase after the Erase Resume.

During Erase Suspend it is possible to Read and Program cells in blocks that are not being erased; both Read and Program operations behave as normal on these blocks. If any attempt is made to program in a protected block or in the suspended block then the Program command is ignored and the data remains unchanged. The Status Register is not read and no error condition is given. Reading from blocks that are being erased will output the Status Register.

It is also possible to issue the Auto Select, Read CFI Query and Unlock Bypass commands during an Erase Suspend. The Read/Reset command must be issued to return the device to Read Array mode before the Resume command will be accepted.

During Erase Suspend a Bus Read operation to the Extended Block will output the Extended Block data. Once in the Extended Block mode, the Exit Extended Block command must be issued before the erase operation can be resumed.

Erase Resume Command

The Erase Resume command is used to restart the Program/Erase Controller after an Erase Suspend. The command must include the Bank Address of the Erase-Suspended Bank, otherwise the Program/Erase Controller is not restarted.

The device must be in Read Array mode before the Resume command will be accepted. An Erase can be suspended and resumed more than once.

Program Suspend Command

The Program Suspend command allows the system to interrupt a program operation so that data can be read from any block. When the Program Suspend command is issued during a program operation, the device suspends the program operation within the Program Suspend Latency time (see Table 7 for value) and updates the Status Register bits. The Bank Addresses of the Block being programmed must be specified in the Program Suspend command.

After the program operation has been suspended, the system can read array data from any address. However, data read from Program-Suspended addresses is not valid.

The Program Suspend command may also be issued during a program operation while an erase is suspended. In this case, data may be read from any addresses not in Erase Suspend or Program

Suspend. If a read is needed from the Extended Block area (One-time Program area), the user must use the proper command sequences to enter and exit this region.

The system may also issue the Auto Select command sequence when the device is in the Program Suspend mode. The system can read as many Auto Select codes as required. When the device exits the Auto Select mode, the device reverts to the Program Suspend mode, and is ready for another valid operation. See Auto Select command sequence for more information.

Program Resume Command

After the Program Resume command is issued, the device reverts to programming. The controller can determine the status of the program operation using the DQ7 or DQ6 status bits, just as in the standard program operation. See Write Operation Status for more information.

The system must write the Program Resume command, specifying the Bank addresses of the Program-Suspended Block, to exit the Program Suspend mode and to continue the programming operation.

Further issuing of the Resume command is ignored. Another Program Suspend command can be written after the device has resumed programming.

Enter Extended Block Command

The M29DW640D has one extra 256-Byte block (Extended Block) that can only be accessed using the Enter Extended Block command. Three Bus write cycles are required to issue the Extended Block command. Once the command has been is-

sued the device enters Extended Block mode where all Bus Read or Program operations to the 000000h-00007Fh (Word) or 000000h-0000FFh (Byte) addresses access the Extended Block. The Extended Block cannot be erased, and can be treated as one-time programmable (OTP) memory. In Extended Block mode only array cell locations (Bank A) with the same addresses as the Extended Block (000000h-00007Fh (Word) or 000000h-0000FFh (Byte)) are not accessible. In Extended Block mode dual operations are allowed and the Extended Block physically belongs to Bank A.

When in Extended Block mode, Erase, Chip Erase, Erase Suspend and Erase resume commands are not allowed.

To exit from the Extended Block mode the Exit Extended Block command must be issued.

The Extended Block can be protected, however once protected the protection cannot be undone.

Exit Extended Block Command

The Exit Extended Block command is used to exit from the Extended Block mode and return the device to Read mode. Four Bus Write operations are required to issue the command.

Block Protect and Chip Unprotect Commands

Groups of blocks can be protected against accidental Program or Erase. The Protection Groups are shown in Appendix A, Table 22, Block Addresses. The whole chip can be unprotected to allow the data inside the blocks to be changed.

Block Protect and Chip Unprotect operations are described in Appendix D.

Table 5. Commands, 16-bit mode, $\overline{BYTE} = V_{IH}$

Command	Length	Bus Write Operations											
		1st		2nd		3rd		4th		5th		6th	
		Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	Add	Data
Read/Reset	1	X	F0										
	3	555	AA	2AA	55	X	F0						
Auto Select	3	555	AA	2AA	55	(BKA) 555	90						
Program	4	555	AA	2AA	55	555	A0	PA	PD				
Double Word Program	3	555	50	PA0	PD0	PA1	PD1						
Quadruple Word Program	3	555	56	PA0	PD0	PA1	PD1	PA2	PD2	PA3	PD3		
Unlock Bypass	3	555	AA	2AA	55	555	20						
Unlock Bypass Program	2	X	A0	PA	PD								
Unlock Bypass Reset	2	X	90	X	00								
Chip Erase	6	555	AA	2AA	55	555	80	555	AA	2AA	55	555	10
Block Erase	6+	555	AA	2AA	55	555	80	555	AA	2AA	55	BA	30
Erase/Program Suspend	1	BKA	B0										
Erase/Program Resume	1	BKA	30										
Read CFI Query[2]	1	(BKA) 55	98										
Enter Extended Block	3	555	AA	2AA	55	555	88						
Exit Extended Block	4	555	AA	2AA	55	555	90	X	00				

Note: 1. X Don't Care, PA Program Address, PD Program Data, BA Any address in the Block, BKA Bank Address. All values in the table are in hexadecimal.

2. Normally the Command Interface only uses A–1, A0-A10 and DQ0-DQ7 to verify the commands and A11-A21 are Don't Care, however for the Read CFI command A21-A14 must specify a bank address, and the subsequent read operations must be addressed to the same bank.

Table 6. Commands, 8-bit mode, $\overline{BYTE} = V_{IL}$

Command	Length	Bus Write Operations																
		1st		2nd		3rd		4th		5th		6th		7th		8th		9th	
		Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	Add	Data	Add	Data
Read/Reset	1	X	F0																
	3	AAA	AA	555	55	X	F0												
Auto Select	3	AAA	AA	555	55	(BKA)AAA	90												
Program	4	AAA	AA	555	55	AAA	A0	PA	PD

Quadruple Byte Program	5	AAA	56	PA0	PD0	PA1	PD1	PA2	PD2	PA3	PD3								
Octuple Byte Program	5	AAA	8B	PA0	PD0	PA1	PD1	PA2	PD2	PA3	PD3	PA4	PD4	PA5	PD5	PA6	PD6	PA7	PD7
Unlock Bypass	3	AAA	AA	555	55	AAA	20												
Unlock Bypass Program	2	X	A0	PA	PD														
Unlock Bypass Reset	2	X	90	X	00														
Chip Erase	6	AAA	AA	555	55	AAA	80	AAA	AA	555	55	AAA	10						
Block Erase	6+	AAA	AA	555	55	AAA	80	AAA	AA	555	55	BA	30						
Erase/Program Suspend	1	BKA	B0																
Erase/Program Resume	1	BKA	30																
Read CFI Query[2]	1	(BKA)AA	98																
Enter Extended Block	3	AAA	AA	555	55	AAA	88												
Exit Extended Block	4	AAA	AA	555	55	AAA	90	X	00										

Note: 1. X Don't Care, PA Program Address, PD Program Data, BA Any address in the Block. All values in the table are in hexadecimal.

2. Normally the Command Interface only uses A–1, A0-A10 and DQ0-DQ7 to verify the commands and A11-A21 are Don't Care, however for the Read CFI command A21-A14 must specify a bank address, and the subsequent read operations must be addressed to the same bank.

Table 7. Program, Erase Times and Program, Erase Endurance Cycles

Parameter	Min	Typ [1, 2]	Max[2]	Unit
Chip Erase		80	400[3]	s
Block Erase (64 KBytes)		0.8	6[4]	s
Erase Suspend Latency Time			50[4]	µs
Byte Program (1, 2, 4 or 8 at-a-time)		10	200[3]	µs
Word Program (1, 2 or 4 at-a-time)		10	200[3]	µs
Chip Program (Byte by Byte)		80	400[3]	s
Chip Program (Word by Word)		40	200[3]	s
Chip Program (Quadruple Byte or Double Word)		20	100[3]	s
Chip Program (Octuple Byte or Quadruple Word)		10	50[3]	s
Program Suspend Latency Time			4	µs
Program/Erase Cycles (per Block)	100,000			cycles
Data Retention	20			years

Note: 1. Typical values measured at room temperature and nominal voltages.
2. Sampled, but not 100% tested.
3. Maximum value measured at worst case conditions for both temperature and V_{CC} after 100,00 program/erase cycles.
4. Maximum value measured at worst case conditions for both temperature and V_{CC}.

STATUS REGISTER

The M29DW640D has one Status Register. The Status Register provides information on the current or previous Program or Erase operations executed in each bank. The various bits convey information and errors on the operation. Bus Read operations from any address within the Bank, always read the Status Register during Program and Erase operations. It is also read during Erase Suspend when an address within a block being erased is accessed.

The bits in the Status Register are summarized in Table 8, Status Register Bits.

Data Polling Bit (DQ7). The Data Polling Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Data Polling Bit is output on DQ7 when the Status Register is read.

During Program operations the Data Polling Bit outputs the complement of the bit being programmed to DQ7. After successful completion of the Program operation the memory returns to Read mode and Bus Read operations from the address just programmed output DQ7, not its complement.

During Erase operations the Data Polling Bit outputs '0', the complement of the erased state of DQ7. After successful completion of the Erase operation the memory returns to Read Mode.

In Erase Suspend mode the Data Polling Bit will output a '1' during a Bus Read operation within a block being erased. The Data Polling Bit will change from a '0' to a '1' when the Program/Erase Controller has suspended the Erase operation.

Figure 7, Data Polling Flowchart, gives an example of how to use the Data Polling Bit. A Valid Address is the address being programmed or an address within the block being erased.

Toggle Bit (DQ6). The Toggle Bit can be used to identify whether the Program/Erase Controller has successfully completed its operation or if it has responded to an Erase Suspend. The Toggle Bit is output on DQ6 when the Status Register is read.

During Program and Erase operations the Toggle Bit changes from '0' to '1' to '0', etc., with successive Bus Read operations at any address. After successful completion of the operation the memory returns to Read mode.

During Erase Suspend mode the Toggle Bit will output when addressing a cell within a block being erased. The Toggle Bit will stop toggling when the Program/Erase Controller has suspended the Erase operation.

Figure 8, Data Toggle Flowchart, gives an example of how to use the Data Toggle Bit.

Error Bit (DQ5). The Error Bit can be used to identify errors detected by the Program/Erase Controller. The Error Bit is set to '1' when a Program, Block Erase or Chip Erase operation fails to write the correct data to the memory. If the Error Bit is set a Read/Reset command must be issued before other commands are issued. The Error bit is output on DQ5 when the Status Register is read.

Note that the Program command cannot change a bit set to '0' back to '1' and attempting to do so will set DQ5 to '1'. A Bus Read operation to that address will show the bit is still '0'. One of the Erase commands must be used to set all the bits in a block or in the whole memory from '0' to '1'.

Erase Timer Bit (DQ3). The Erase Timer Bit can be used to identify the start of Program/Erase Controller operation during a Block Erase command. Once the Program/Erase Controller starts erasing the Erase Timer Bit is set to '1'. Before the Program/Erase Controller starts the Erase Timer Bit is set to '0' and additional blocks to be erased may be written to the Command Interface. The Erase Timer Bit is output on DQ3 when the Status Register is read.

Alternative Toggle Bit (DQ2). The Alternative Toggle Bit can be used to monitor the Program/Erase controller during Erase operations. The Alternative Toggle Bit is output on DQ2 when the Status Register is read.

During Chip Erase and Block Erase operations the Toggle Bit changes from '0' to '1' to '0', etc., with successive Bus Read operations from addresses within the blocks being erased. A protected block is treated the same as a block not being erased. Once the operation completes the memory returns to Read mode.

During Erase Suspend the Alternative Toggle Bit changes from '0' to '1' to '0', etc. with successive Bus Read operations from addresses within the blocks being erased. Bus Read operations to addresses within blocks not being erased will output the memory cell data as if in Read mode.

After an Erase operation that causes the Error Bit to be set the Alternative Toggle Bit can be used to identify which block or blocks have caused the error. The Alternative Toggle Bit changes from '0' to '1' to '0', etc. with successive Bus Read Operations from addresses within blocks that have not erased correctly. The Alternative Toggle Bit does not change if the addressed block has erased correctly.

Table 8. Status Register Bits

Operation	Address	DQ7	DQ6	DQ5	DQ3	DQ2	R$\overline{B}$
Program	Bank Address	$\overline{DQ7}$	Toggle	0	–	–	0
Program During Erase Suspend	Bank Address	$\overline{DQ7}$	Toggle	0	–	–	0
Program Error	Bank Address	$\overline{DQ7}$	Toggle	1	–	–	0
Chip Erase	Any Address	0	Toggle	0	1	Toggle	0
Block Erase before timeout	Erasing Block	0	Toggle	0	0	Toggle	0
	Non-Erasing Block	0	Toggle	0	0	No Toggle	0
Block Erase	Erasing Block	0	Toggle	0	1	Toggle	0
	Non-Erasing Block	0	Toggle	0	1	No Toggle	0
Erase Suspend	Erasing Block	1	No Toggle	0	–	Toggle	Hi-Z
	Non-Erasing Block	Data read as normal					Hi-Z
Erase Error	Good Block Address	0	Toggle	1	1	No Toggle	0
	Faulty Block Address	0	Toggle	1	1	Toggle	0

Note: Unspecified data bits should be ignored.

AI07760

Figure 8. Data Toggle Flowchart

AI07760
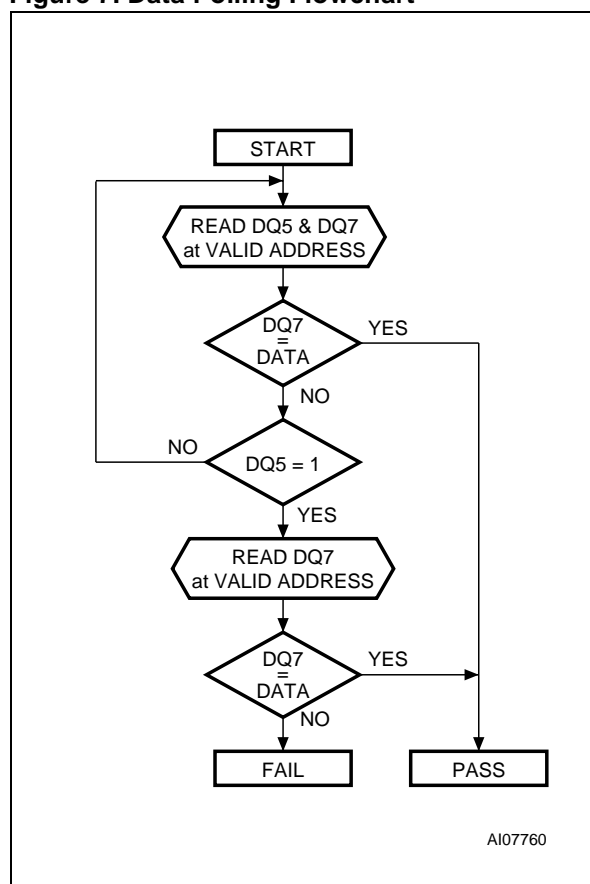

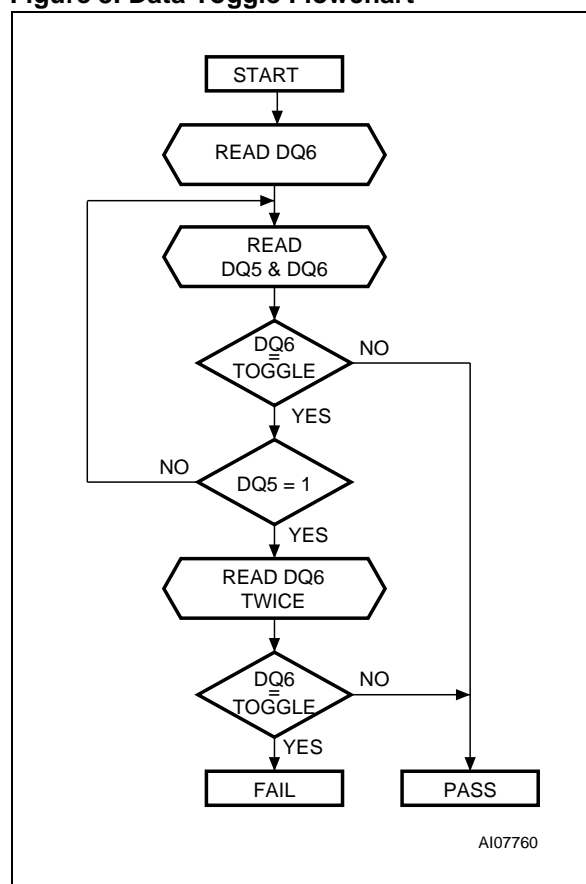

DUAL OPERATIONS AND MULTIPLE BANK ARCHITECTURE

The Multiple Bank Architecture of the M29DW640D gives greater flexibility for software developers to split the code and data spaces within the memory array. The Dual Operations feature simplifies the software management of the device by allowing code to be executed from one bank while another bank is being programmed or erased.

The Dual Operations feature means that while programming or erasing in one bank, read operations are possible in another bank with zero latency.

Only one bank at a time is allowed to be in program or erase mode. However, certain commands can cross bank boundaries, which means that during an operation only the banks that are not concerned with the cross bank operation are available for dual operations. For example, if a Block Erase command is issued to erase blocks in both Bank A and Bank B, then only Banks C or D are available for read operations while the erase is being executed.

If a read operation is required in a bank, which is programming or erasing, the program or erase operation can be suspended.

Also if the suspended operation was erase then a program command can be issued to another block, so the device can have one block in Erase Suspend mode, one programming and other banks in read mode.

By using a combination of these features, read operations are possible at any moment in the M29DW640D device.

Tables 9 and 10 show the dual operations possible in other banks and in the same bank. Note that only the commonly used commands are represented in these tables.

Table 9. Dual Operations Allowed In Other Banks

Status of bank[1]	Commands allowed in another bank[1]							
	Read Array	Read Status Register	Read CFI Query	Auto Select	Program	Erase	Program/ Erase Suspend	Program/ Erase Resume
Idle	Yes	Yes[2]	Yes	Yes	Yes	Yes	Yes[2]	Yes[3]
Programming	Yes	No	No	No	–	–	No	No
Erasing	Yes	No	No	No	–	–	No	No
Program Suspended	Yes	No	Yes	Yes	No	No	Yes[4]	No
Erase Suspended	Yes	No	Yes	Yes	Yes	No	No	Yes[5]

Note: 1. If several banks are involved in a program or erase operation, then only the banks that are not concerned with the operation are available for dual operations.
2. Only after a program or erase operation in that bank.
3. Only after a Program or Erase Suspend command in that bank.
4. Only an Erase Resume is allowed if the bank was previously in Erase Suspend mode.
5. Only a Program Resume is allowed if the bank was previously in Program Suspend mode.

Table 10. Dual Operations Allowed In Same Bank

Status of bank	Commands allowed in same bank							
	Read Array	Read Status Register	Read CFI Query	Auto Select	Program	Erase	Program/ Erase Suspend	Program/ Erase Resume
Idle	Yes	Yes	Yes	Yes	Yes	Yes	Yes[2]	Yes[3]
Programming	No	Yes	No	No	–	–	Yes[4]	–
Erasing	No	Yes	No	No	–	No	Yes[5]	–
Program Suspended	Yes[1]	No	Yes	Yes	No	–	–	Yes
Erase Suspended	Yes[1]	No	Yes	Yes	Yes[1]	No	–	Yes

Note: 1. Not allowed in the Block or Word that is being erased or programmed.
2. Only after a program or erase operation in that bank.
3. Only after a Program or Erase Suspend command in that bank.
4. Only a Program Suspend.
5. Only an Erase suspend.

MAXIMUM RATING

Stressing the device above the rating listed in the Absolute Maximum Ratings table may cause permanent damage to the device. Exposure to Absolute Maximum Rating conditions for extended periods may affect device reliability. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the Operating sections of this specification is not implied. Refer also to the STMicroelectronics SURE Program and other relevant quality documents.

Table 11. Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Unit
T_{BIAS}	Temperature Under Bias	−50	125	°C
T_{STG}	Storage Temperature	−65	150	°C
V_{IO}	Input or Output Voltage [1,2]	−0.6	V_{CC} +0.6	V
V_{CC}	Supply Voltage	−0.6	4	V
V_{ID}	Identification Voltage	−0.6	13.5	V
V_{PP}[3]	Program Voltage	−0.6	13.5	V

Note: 1. Minimum voltage may undershoot to −2V during transition and for less than 20ns during transitions.
2. Maximum voltage may overshoot to V_{CC} +2V during transition and for less than 20ns during transitions.
3. V_{PP} must not remain at 12V for more than a total of 80hrs.

DC AND AC PARAMETERS

This section summarizes the operating measurement conditions, and the DC and AC characteristics of the device. The parameters in the DC and AC characteristics Tables that follow, are derived from tests performed under the Measurement Conditions summarized in Table 12, Operating and AC Measurement Conditions. Designers should check that the operating conditions in their circuit match the operating conditions when relying on the quoted parameters.

Table 12. Operating and AC Measurement Conditions

Parameter	M29DW640D				Unit
	70		**90**		
	Min	**Max**	**Min**	**Max**	
V_{CC} Supply Voltage	3.0	3.6	2.7	3.6	V
Ambient Operating Temperature	−40	85	−40	85	°C
Load Capacitance (C_L)	30		30		pF
Input Rise and Fall Times		10		10	ns
Input Pulse Voltages	0 to V_{CC}		0 to V_{CC}		V
Input and Output Timing Ref. Voltages	$V_{CC}/2$		$V_{CC}/2$		V

Table 13. Device Capacitance

Symbol	Parameter	Test Condition	Min	Max	Unit
C_{IN}	Input Capacitance	$V_{IN} = 0V$		6	pF
C_{OUT}	Output Capacitance	$V_{OUT} = 0V$		12	pF

Note: Sampled only, not 100% tested.

Table 14. DC Characteristics

Symbol	Parameter	Test Condition		Min	Max	Unit
I_{LI}	Input Leakage Current	$0V \leq V_{IN} \leq V_{CC}$			±1	µA
I_{LO}	Output Leakage Current	$0V \leq V_{OUT} \leq V_{CC}$			±1	µA
I_{CC1}[2]	Supply Current (Read)	$\overline{E} = V_{IL}$, $\overline{G} = V_{IH}$, f = 6MHz			10	mA
I_{CC2}	Supply Current (Standby)	$\overline{E} = V_{CC}$ ±0.2V, $\overline{RP} = V_{CC}$ ±0.2V			100	µA
I_{CC3} [1,2]	Supply Current (Program/Erase)	Program/Erase Controller active	$V_{PP}/\overline{WP}$ = V_{IL} or V_{IH}		20	mA
			$V_{PP}/\overline{WP} = V_{PP}$		20	mA
V_{IL}	Input Low Voltage			−0.5	0.8	V
V_{IH}	Input High Voltage			$0.7V_{CC}$	V_{CC} +0.3	V
V_{PP}	Voltage for $V_{PP}/\overline{WP}$ Program Acceleration	V_{CC} = 3.0V ±10%		11.5	12.5	V
I_{PP}	Current for $V_{PP}/\overline{WP}$ Program Acceleration	V_{CC} = 3.0V ±10%			15	mA
V_{OL}	Output Low Voltage	I_{OL} = 1.8mA			0.45	V
V_{OH}	Output High Voltage	I_{OH} = −100µA		V_{CC} −0.4		V
V_{ID}	Identification Voltage			11.5	12.5	V
V_{LKO}	Program/Erase Lockout Supply Voltage			1.8	2.3	V

Note: 1. Sampled only, not 100% tested.
2. In Dual operations the Supply Current will be the sum of I_{CC1}(read) and I_{CC3} (program/erase).

PART NUMBERING

Table 21. Ordering Information Scheme

Example: M29DW640D   70   N   1   T

Device Type
M29

Architecture
D = Multiple Bank

Operating Voltage
W = V_{CC} = 2.7 to 3.6V

Device Function
640D = 64 Mbit (x8/x16), Boot Block, 8+24+24+8 partitioning

Speed
70 = 70ns
90 = 90ns

Package
N = TSOP48: 12 x 20 mm
ZA = FBGA63: 7 x 11mm, 0.80 mm pitch

Temperature Range
1 = 0 to 70 °C
6 = –40 to 85 °C

Option
Blank = Standard Packing
T = Tape & Reel Packing
E = Lead-free Package, Standard Packing
F = Lead-free Package, Tape & Reel Packing

Note: This product is also available with the Extended Block factory locked. For further details and ordering information contact your nearest ST sales office.

Devices are shipped from the factory with the memory content bits erased to '1'.

For a list of available options (Speed, Package, etc.) or for further information on any aspect of this device, please contact your nearest ST Sales Office.

APPENDIX A. BLOCK ADDRESSES

Table 22. Block Addresses

APPENDIX B. COMMON FLASH INTERFACE (CFI)

The Common Flash Interface is a JEDEC approved, standardized data structure that can be read from the Flash memory device. It allows a system software to query the device to determine various electrical and timing parameters, density information and functions supported by the memory. The system can interface easily with the device, enabling the software to upgrade itself when necessary.

When the Read CFI Query command is issued the addressed bank enters Read CFI Query mode and

read operations in the same bank (A21-A14) output the CFI data. Tables 23, 24, 25, 26, 27 and 28 show the addresses (A-1, A0-A10) used to retrieve the data.

The CFI data structure also contains a security area where a 64 bit unique security number is written (see Table 28, Security Code area). This area can be accessed only in Read mode by the final user. It is impossible to change the security number after it has been written by ST.

Table 23. Query Structure Overview

Address		Sub-section Name	Description
x16	x8		
10h	20h	CFI Query Identification String	Command set ID and algorithm data offset
1Bh	36h	System Interface Information	Device timing & voltage information
27h	4Eh	Device Geometry Definition	Flash device layout
40h	80h	Primary Algorithm-specific Extended Query table	Additional information specific to the Primary Algorithm (optional)
61h	C2h	Security Code Area	64 bit unique device number

Note: Query data are always presented on the lowest order data outputs.

Table 24. CFI Query Identification String

Address		Data	Description	Value
x16	x8			
10h	20h	0051h		"Q"
11h	22h	0052h	Query Unique ASCII String "QRY"	"R"
12h	24h	0059h		"Y"
13h	26h	0002h	Primary Algorithm Command Set and Control Interface ID code 16 bit ID code defining a specific algorithm	AMD Compatible
14h	28h	0000h		
15h	2Ah	0040h	Address for Primary Algorithm extended Query table (see Table 27)	P = 40h
16h	2Ch	0000h		
17h	2Eh	0000h	Alternate Vendor Command Set and Control Interface ID Code second vendor - specified algorithm supported	NA
18h	30h	0000h		
19h	32h	0000h	Address for Alternate Algorithm extended Query table	NA
1Ah	34h	0000h		

Note: Query data are always presented on the lowest order data outputs (DQ7-DQ0) only. DQ8-DQ15 are '0'.

Table 25. CFI Query System Interface Information

Address		Data	Description	Value
x16	**x8**			
1Bh	36h	0027h	V_{CC} Logic Supply Minimum Program/Erase voltage bit 7 to 4　　　　BCD value in volts bit 3 to 0　　　　BCD value in 100 mV	2.7V
1Ch	38h	0036h	V_{CC} Logic Supply Maximum Program/Erase voltage bit 7 to 4　　　　BCD value in volts bit 3 to 0　　　　BCD value in 100 mV	3.6V
1Dh	3Ah	00B5h	V_{PP} [Programming] Supply Minimum Program/Erase voltage bit 7 to 4　　　　HEX value in volts bit 3 to 0　　　　BCD value in 100 mV	11.5V
1Eh	3Ch	00C5h	V_{PP} [Programming] Supply Maximum Program/Erase voltage bit 7 to 4　　　　HEX value in volts bit 3 to 0　　　　BCD value in 100 mV	12.5V
1Fh	3Eh	0004h	Typical timeout per single Byte/Word program = 2^n µs	16µs
20h	40h	0000h	Typical timeout for minimum size write buffer program = 2^n µs	NA
21h	42h	000Ah	Typical timeout per individual block erase = 2^n ms	1s
22h	44h	0000h	Typical timeout for full chip erase = 2^n ms	NA
23h	46h	0004h	Maximum timeout for Byte/Word program = 2^n times typical	256 µs
24h	48h	0000h	Maximum timeout for write buffer program = 2^n times typical	NA
25h	4Ah	0003h	Maximum timeout per individual block erase = 2^n times typical	8s
26h	4Ch	0000h	Maximum timeout for chip erase = 2^n times typical	NA

Table 26. Device Geometry Definition

Address		Data	Description	Value
x16	**x8**			
27h	4Eh	0017h	Device Size = 2^n in number of Bytes	8 MBytes
28h 29h	50h 52h	0002h 0000h	Flash Device Interface Code description	x8, x16 Async.
2Ah 2Bh	54h 56h	0003h 0000h	Maximum number of Bytes in multi-Byte program or page = 2^n	8
2Ch	58h	0003h	Number of Erase Block Regions[1]. It specifies the number of regions containing contiguous Erase Blocks of the same size.	3
2Dh 2Eh	5Ah 5Ch	0007h 0000h	Erase Block Region 1 Information Number of identical size erase block = 0007h+1	8
2Fh 30h	5Eh 60h	0020h 0000h	Erase Block Region 1 Information Block size in Region 1 = 0020h * 256 Byte	8 KBytes
31h 32h	62h 64h	007Dh 0000h	Erase Block Region 2 Information Number of identical size erase block = 007Dh+1	126
33h 34h	66h 68h	0000h 0001h	Erase Block Region 2 Information Block size in Region 2 = 0100h * 256 Byte	64 KBytes
35h 36h	6Ah 6Ch	0007h 0000h	Erase Block Region 3 information Number of identical size erase block = 0007h + 1	8
37h 38h	6Eh 60h	0020h 0000h	Erase Block Region 3 information Block size in region 3 = 0020h * 256 Bytes	8 KBytes

Note: 1. Erase Block Region 1 corresponds to addresses 000000h to 007FFFh; Erase block Region 2 corresponds to addresses 008000h to 3F7FFFh; and Erase Block Region 3 corresponds to addresses 3F8000h to 3FFFFFh.

Table 27. Primary Algorithm-Specific Extended Query Table

Address		Data	Description	Value

63h	C7h, C6h	XXXX	
64h	C9h, C8h	XXXX	

APPENDIX C. EXTENDED MEMORY BLOCK

The M29DW640D has an extra block, the Extended Block, that can be accessed using a dedicated command.

This Extended Block is 128 Words in x16 mode and 256 Bytes in x8 mode. It is used as a security block (to provide a permanent security identification number) or to store additional information.

The Extended Block is either Factory Locked or Customer Lockable, its status is indicated by bit DQ7. This bit is permanently set to either '1' or '0' at the factory and cannot be changed. When set to '1', it indicates that the device is factory locked and the Extended Block is protected. When set to '0', it indicates that the device is customer lockable and the Extended Block is unprotected. Bit DQ7 being permanently locked to either '1' or '0' is another security feature which ensures that a customer lockable device cannot be used instead of a factory locked one.

Bit DQ7 is the most significant bit in the Extended Block Verify Code and a specific procedure must be followed to read it. See "Extended Block Indicator Bit" in Tables 3 and 4, Bus Operations, BYTE = V_{IL} and Bus Operations, BYTE = V_{IH}, respectively, for details of how to read bit DQ7.

The Extended Block can only be accessed when the device is in Extended Block mode. For details of how the Extended Block mode is entered and exited, refer to the Enter Extended Block Command and Exit Extended Block Command paragraphs, and to Tables 5 and 6, "Commands, 16-bit mode, BYTE = V_{IH}" and "Commands, 8-bit mode, BYTE = V_{IL}", respectively.

Factory Locked Extended Block

In devices where the Extended Block is factory locked, the Security Identification Number is written to the Extended Block address space (see Table 29, Extended Block Address and Data) in the factory. The DQ7 bit is set to '1' and the Extended Block cannot be unprotected.

Customer Lockable Extended Block

A device where the Extended Block is customer lockable is delivered with the DQ7 bit set to '0' and the Extended Block unprotected. It is up to the customer to program and protect the Extended Block but care must be taken because the protection of the Extended Block is not reversible.

There are two ways of protecting the Extended Block:

■ Issue the Enter Extended Block command to place the device in Extended Block mode, then use the In-System Technique (refer to Appendix D, In-System Technique and to the corresponding flowcharts, Figures 21 and 22, for a detailed explanation of the technique).

■ Issue the Enter Extended Block command to place the device in Extended Block mode, then use the Programmer Technique (refer to Appendix D, Programmer Technique and to the corresponding flowcharts, Figures 19 and 20, for a detailed explanation of the technique).

Once the Extended Block is programmed and protected, the Exit Extended Block command must be issued to exit the Extended Block mode and return the device to Read mode.

Table 29. Extended Block Address and Data

Device	Address[1]		Data		
	x8	x16	Factory Locked		Customer Lockable
M29DW640D	000000h-00000Fh	000000h-000007h	Random Number	Security Identification Number	Determined by Customer
	000010h-000020h	000008h-00000Fh	ESN[2]		
	000021h-0000FFh	000010h-00007Fh	Unavailable		

Note: 1. See Tables 22, Block Addresses.
2. ENS = Electronic Serial Number.

APPENDIX D. BLOCK PROTECTION

Block protection can be used to prevent any operation from modifying the data stored in the memory. The blocks are protected in groups, refer to Appendix A, Table 22 for details of the Protection Groups. Once protected, Program and Erase operations within the protected group fail to change the data.

There are three techniques that can be used to control Block Protection, these are the Programmer technique, the In-System technique and Temporary Unprotection. Temporary Unprotection is controlled by the Reset/Block Temporary Unprotection pin, $\overline{RP}$; this is described in the Signal Descriptions section.

To protect the Extended Block issue the Enter Extended Block command and then use either the Programmer or In-System technique. Once protected issue the Exit Extended Block command to return to read mode. The Extended Block protection is irreversible, once protected the protection cannot be undone.

Programmer Technique

The Programmer technique uses high (V_{ID}) voltage levels on some of the bus pins. These cannot be achieved using a standard microprocessor bus, therefore the technique is recommended only for use in Programming Equipment.

To protect a group of blocks follow the flowchart in Figure 19, Programmer Equipment Block Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the groups first, then all groups can be unprotected at the same time. To unprotect the chip follow Figure 20, Programmer Equipment Chip Unprotect Flowchart. Table 30,

Programmer Technique Bus Operations, gives a summary of each operation.

The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.

In-System Technique

The In-System technique requires a high voltage level on the Reset/Blocks Temporary Unprotect pin, $\overline{RP}$. This can be achieved without violating the maximum ratings of the components on the microprocessor bus, therefore this technique is suitable for use after the memory has been fitted to the system.

To protect a group of blocks follow the flowchart in Figure 21, In-System Block Protect Flowchart. To unprotect the whole chip it is necessary to protect all of the groups first, then all the groups can be unprotected at the same time. To unprotect the chip follow Figure 22, In-System Chip Unprotect Flowchart.

The timing on these flowcharts is critical. Care should be taken to ensure that, where a pause is specified, it is followed as closely as possible. Do not allow the microprocessor to service interrupts that will upset the timing and do not abort the procedure before reaching the end. Chip Unprotect can take several seconds and a user message should be provided to show that the operation is progressing.

Table 30. Programmer Technique Bus Operations, $\overline{BYTE}$ = V$_{IH}$ or V$_{IL}$

Operation	$\overline{E}$	$\overline{G}$	$\overline{W}$	Address Inputs A0-A21	Data Inputs/Outputs DQ15A–1, DQ14-DQ0
Block (Group) Protect[1]	V$_{IL}$	V$_{ID}$	V$_{IL}$ Pulse	A9 = V$_{ID}$, A12-A21 Block Address Others = X	X
Chip Unprotect	V$_{ID}$	V$_{ID}$	V$_{IL}$ Pulse	A9 = V$_{ID}$, A12 = V$_{IH}$, A15 = V$_{IH}$ Others = X	X
Block (Group) Protect Verify	V$_{IL}$	V$_{IL}$	V$_{IH}$	A0 = V$_{IL}$, A1 = V$_{IH}$, A2 = V$_{IL}$, A3 = V$_{IL}$, A6 = V$_{IL}$, A9 = V$_{ID}$, A12-A21 Block Address Others = X	Pass = xx01h Retry = xx00h.
Block (Group) Unprotect Verify	V$_{IL}$	V$_{IL}$	V$_{IH}$	A0 = V$_{IL}$, A1 = V$_{IH}$, A2 = V$_{IL}$, A3 = V$_{IL}$, A6 = V$_{IH}$, A9 = V$_{ID}$, A12-A21 Block Address Others = X	Pass = xx00h Retry = xx01h.

REVISION HISTORY

Table 31. Document Revision History

Date	Version	Revision Details
10-Dec-2002	1.0	Document written
27-Feb-2003	1.1	Typical after 100k W/E Cycles column removed from Table 7, Program, Erase Times and Program, Erase Endurance Cycles, and Data Retention and Erase Suspend Latency Time parameters added. Device code corrected. Address on DQ7-DQ0 modified for the cycle No.2 of the Read Device code in Table 3, Bus Operations, BYTE = V_{IL}. Lead-free package options E and F added to Table 21, Ordering Information Scheme.
01-Apr-2003	1.2	Document Status promoted to Preliminary Data. Page mode added, Appendix C "Extended Memory Block" added. V_{SS} signal description clarified. Parameter I_{ID} removed from DC Characteristics Table. Read CFI Query command address clarified. Program Suspend Latency time added to Table 7, Program, Erase Times and Program and Erase Endurance Cycles. Dual operations section added.
15-May-2003	1.3	Note added to Table 21, Ordering Information Scheme. Table 19, TSOP48 – 48 lead Plastic Thin Small Outline, 12 x 20mm, Package Mechanical Data and Figure 17, TSOP48 – 48 lead Plastic Thin Small Outline, 12 x 20mm, Package Outline, modified. Data modified at addresses 4Ah and 4Fh in Table 27, Primary Algorithm-Specific Extended Query Table and at address 2Ch in Table 26, Device Geometry Definition.
18-Jul-2003	2.0	Note 1 removed from: Figures 5 and 6, Block Address (x8 and x16, respectively), and from Table 22, Block Addresses. RB bit is High-Z (instead of 1), in Table 8. Auto Select Command description modified. Extended Memory Block size modified in Appendix C.
