

The SL6619 is an advanced Direct Conversion FSK Data Receiver for operation up to 450 MHz. The device integrates all functions to convert a binary FSK modulated RF signal into a demodulated data stream.

Adjacent channel rejection is provided using tuneable gyrator filters. RF and audio AGC functions assist operation when large interfering signals are present and an automatic frequency control (AFC) function is provided to extend centre frequency acceptance.

**Features**

- Very Low Power Operation from Single Cell
- Superior Sensitivity
- Operation at 512, 1200 and 2400 Baud
- On Chip 1 Volt Regulator
- 1mm Height Miniature Package
- Automatic Frequency Control Function
- Programmable Post Detection Filter
- AGC Detection Circuitry
- Power Down Function
- Battery Strength Indicator

**Applications**

- Pagers, including Credit Card, PCMCIA and Watch Pagers
- Low Data Rate Receivers, e.g. Security Systems

Ordering Information		
SL6619/KG/TP1N	32 Pin TQFP	Trays
SL6619/KG/TP1Q	32 Pin TQFP	Tape & Reel
SL6619/KG/TP2Q	32 Pin TQFP*	Tape & Reel
SL6619/KG/TP2N	32 Pin TQFP*	Trays

\*Pb Free Matte Tin

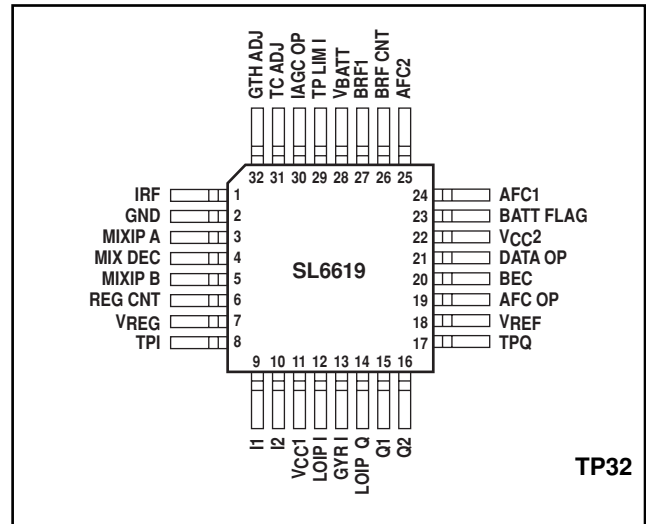

Figure 1 Pin identification diagram (top view). See Table 1 for pin descriptions

**ABSOLUTE MAXIMUM RATINGS**

Storage temperature	-55°C to +150°C
Operating temperature	-10°C to +55°C
Maximum voltage on any pin w.r.t. any other pin, subject to the following conditions:	+4V
Current, pin 3 (MIXIP), pin 5 (MIXPB), pin 12 (LOIP I) and pin 14 (LOIPB)	<5ma
Most negative voltage on any pin	-0.5V w.r.t. gnd

	65	75	76	dB	2400bps, $\Delta f = 4.5\text{kHz}$ . LO = $-15\text{dBm}$

## Operation of SL6619

### Low Noise Amplifier

To achieve optimum performance it is necessary to incorporate a Low Noise RF Amplifier at the front end of the receiver. This is easily biased using the on-chip voltages and current source provided. All voltages and current sources used for bias of the RF amplifier, receiver and mixers should be RF decoupled using 1nF capacitors. The receiver also requires a stable Local Oscillator at the required channel frequency.

### Local Oscillator

The Local Oscillator signal is applied to the device in phase quadrature. This can be achieved with the use of two RC networks operating at their  $-3\text{dB}/45^\circ$  transfer characteristic. The RC characteristics for I and Q channels are combined to give a full  $90^\circ$  phase differential between the LO ports of the device. Each LO port also requires an equal level of drive from the oscillator. This is achieved by forming the two RC networks into a power divider.

### Gyrator Filters

The on-chip filters include an adjustable gyrator filter. This may be adjusted by changing the value of the resistor connected between pin 13 and GND. This allows adjustment of the filters' cutoff frequency and allows for compensation for possible process variations.

### Audio AGC (Fig. 3)

The Audio AGC consists of a current sink which is controlled by the audio (baseband) signal. It has three parameters that may be controlled by the user. These are the attack (turn on) time, decay (duration) time and threshold level. The attack time is simply determined by the value of the external capacitor connected to TCADJ. The external capacitor is in series with an internal  $100\text{k}\Omega$  resistor and the time constant of this circuit dictates the attack time of the AGC.

$$\text{i.e. } t_{\text{ATTACK}} = 100\text{k}\Omega \times C18$$

The decay time is determined by the external resistor connected in parallel with the capacitor CTC. The decay time is simply

$$t_{\text{DECAY}} = R17 \times C18$$

When a large audio (baseband) signal is incident on the input to the AGC circuit, the variable current source is turned on. This causes a voltage drop across R13. The voltage potential between  $V_{\text{REF}}$  and the voltage on pin 31 causes a current to flow in pin 30. This charges up C18 through the  $100\text{k}\Omega$  internal resistor. As the voltage across the capacitor increases, a current source is turned on and this sinks current from pin 32. The current sink on pin 32 can be used to drive

the external AGC circuit by causing a PIN diode to conduct, reducing the signal to the RF amplifier.

### RF AGC

The RF AGC is an automatic gain control loop that protects the mixer's RF inputs, Pins 3 and 5, from large out of band RF signals. The loop consists of an RF received signal strength indicator which detect the signal at the inputs of the mixers. This RSSI signal is then used to control the LNA current source (pin 1).

### Regulator

The on-chip regulator should be used in conjunction with a suitable PNP transistor to achieve regulation. As the transistor forms part of the regulator feedback loop the transistor should exhibit the following characteristics:

$$H_{\text{FE}} > 100 \text{ for } V_{\text{CE}} > 0.1\text{V}$$

If no external transistor is used, the maximum current sourcing capability of the regulator is limited to  $30\mu\text{A}$ .

### Automatic Frequency Control (Fig. 4)

The Automatic Frequency Control consists of a detection circuit which gives a current output at AFC OP whose magnitude and sign is a function of the difference between the local oscillator ( $f_{\text{LO}}$ ) and carrier frequencies ( $f_{\text{C}}$ ). This output current is then filtered by an off-chip integrating capacitor. The integrator's output voltage is used to control a voltage control crystal oscillator. This closes the AFC feedback loop giving the automatic frequency control function. For an FSK modulated incoming RF carrier, the AFC OP current's polarity is positive, i.e. current is sourced for  $f_{\text{LO}} < f_{\text{C}} < f_{\text{LO}} + 4\text{kHz}$  and negative, i.e. current is sunk, for  $f_{\text{LO}} > f_{\text{C}} > f_{\text{LO}} - 4\text{kHz}$ . The magnitude of the AFC OP current is a function of frequency offset and the transmitted data's bit stream. If the carrier frequency, ( $f_{\text{C}}$ ), equals the local oscillator frequency, ( $f_{\text{LO}}$ ) then the magnitude of the current is zero.

### BIT RATE FILTER CONTROL

The logic level on pin 26 controls the cutoff frequency of the 1st order bit rate for a given bit rate filter capacitor at pin 27. This allows the cutoff frequency to be changed between  $f_{\text{C}}$ ,  $2f_{\text{C}}$  and  $0.43f_{\text{C}}$  through the logic level on pin 26. This function is achieved by changing the value of the current in the  $4\phi$  detector's output stage. A logic zero (0V to 0.1V) on pin 26 gives a cutoff frequency of  $f_{\text{C}}$  a logic one ( $V_{\text{CC}2} - 0.3\text{V}$  to  $V_{\text{CC}2}$ ) gives a cut off frequency of  $2f_{\text{C}}$  and an open circuit at pin 26 gives a cutoff frequency of  $0.43f_{\text{C}}$ .

NOTE	SQUARE			

Conforms to JEDEC MS-026 ABA Iss. C

Notes:

1. Pin 1 indicator may be a corner chamfer, dot or both.
2. Controlling dimensions are in millimeters.
3. The top package body size may be smaller than the bottom package body size by a max. of 0.15 mm.
4. Dimension D1 and E1 do not include mould protusion.
5. Dimension b does not include dambar protusion.
6. Coplanarity, measured at seating plane G, to be 0.10 mm max.
