## Features

- Compensation Pin for Bandwidth Limiting
- Lower Lot-to-Lot Variability With External Compensation
- High Input Impedance . . . . . . . . . . . . . . . . . . . . . . . 1 M $\Omega$
- Differential Gain
0.02\%
- Differential Phase . . . . . . . . . . . . . . . . . 0.05 Degrees
- Wide -3dB Bandwidth . . . . . . . . . . . . . . . . . . . 315MHz
- Very Fast Slew Rate. . . . . . . . . . . . . . . . . . . . . . 700V/ $\mu \mathrm{s}$
- Low Supply Current. . . . . . . . . . . . . . . . . . . . . . . 5.8mA
- Gain Flatness (to 100 MHz ) . . . . . . . . . . . . . . . . $\pm 0.1 \mathrm{~dB}$

## Applications

- Noise Critical Applications
- Professional Video Processing
- Medical Imaging
- Video Digitizing Boards/Systems
- Radar/IF Processing
- Hand Held and Miniaturized RF Equipment
- Battery Powered Communications
- Flash A/D Drivers
- Oscilloscopes and Analyzers

## Description

The HFA1106 is a high speed, low power current feedback operational amplifier built with Intersil's proprietary complementary bipolar UHF-1 process. This amplifier features a compensation pin connected to the internal high impedance node, which allows for implementation of external clamping or bandwidth limiting.

Bandwidth limiting is accomplished by connecting a capacitor ( $\mathrm{C}_{\mathrm{COMP}}$ ) and series damping resistor ( $\mathrm{R}_{\mathrm{COMP}}$ ) from pin 8 to ground. Amplifier performance for various values of $\mathrm{C}_{\text {COMP }}$ is documented in the Electrical Specifications.

The HFA1106 is ideal for noise critical wideband applications. Not only can the bandwidth be limited to minimize broadband noise, the HFA1106 is optimized for lower feedback resistors ( $R_{F}=100 \Omega$ for $A_{V}=+2$ ) than most current feedback amplifiers. The low feedback resistor reduces the inverting input noise current contribution to total output noise, while reducing DC errors as well. Please see the "Application Information" section for details.

## Operating Conditions

## Thermal Information

| Thermal Resistance (Typical, Note 2) | $\theta_{\mathrm{JA}}\left({ }^{\circ} \mathrm{C} / \mathrm{W}\right)$ |
| :---: | :---: |
| PDIP Package | 130 |
| SOIC Package | 170 |
| Maximum Junction Temperature (Die Only) | C |
| Maximum Junction Temperature (Plastic Package) | $150^{\circ} \mathrm{C}$ |
| Maximum Storage Temperature Range | $5^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ |
| Maximum Lead Temperature (Soldering 10s). (SOIC - Lead Tips Only) | $300^{\circ} \mathrm{C}$ |

Temperature Range $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

NOTES:

1. Output is short circuit protected to ground. Brief short circuits to ground will not degrade reliability; however, continuous ( $100 \%$ duty cycle) output current must not exceed 30 mA for maximum reliability.
2. $\theta_{\mathrm{JA}}$ is measured with the component mounted on an evaluation PC board in free air.

NOTES:
3. Test Level: A. Production Tested; B. Typical or Guaranteed Limit Based on Characterization; C. Design Typical for Information Only.
4. Undershoot dominates for output signal swings below GND (e.g. $2 \mathrm{~V}_{\mathrm{P}-\mathrm{P}}$ ) yielding a higher overshoot limit compared to the $\mathrm{V}_{\mathrm{OUT}}=0 \mathrm{~V}$ to 2 V condition.

## Application Information

## Optimum Feedback Resistor

All current feedback amplifiers (CFAs) require a feedback resistor ( $R_{F}$ ) even for unity gain applications, and $R_{F}$ in conjunction with the internal compensation capacitor sets the dominant pole of the frequency response. Thus the amplifier's bandwidth is inversely proportional to $R_{F}$. The HFA1106 design is optimized for $R_{F}=150 \Omega$ at a gain of +1 . Decreasing $R_{F}$ decreases stability resulting in excessive peaking and overshoot - Note: Capacitive feedback causes the same problems due to the feedback impedance decrease at higher frequencies. At higher gains, however, the amplifier is more stable, so $R_{F}$ can be decreased in a trade-off of stability for bandwidth (e.g., $R_{F}=100 \Omega$ for $A_{V}=+2$ ).

## Why Use Externally Compensated Amplifiers?

Externally compensated op amps were originally developed to allow operation at gains below the amplifier's minimum stable gain. This enabled development of non-unity gain stable op amps with very high bandwidth and slew rates. Users needing lower closed loop gains could stabilize the amplifier with external compensation if the associated performance decrease was tolerable.

With the advent of CFAs, unity gain stability and high performance are no longer mutually exclusive, so why offer unity gain stable op amps with compensation pins?

The main reason for external compensation is to allow users to tailor the amplifier's performance to their specific system needs. Bandwidth can be limited to the exact value required, thereby eliminating excess bandwidth and its associated noise. A compensated op amp is also more predictable; lower lot-to-lot variation requires less system overdesign to cover process variability. Finally, access to the internal high impedance node allows users to implement external output limiting or allows for stabilizing the amplifier when driving large capacitive loads.

## Noise Advantages - Uncompensated

The HFA1106 delivers lower broadband noise even without an external compensation capacitor. Package capacitance present at the Comp pin stabilizes the op amp, so lower value feedback resistors can be used. A smaller value $R_{F}$ minimizes the noise voltage contribution of the amplifier's inverting input noise current $-I_{N I} \times R_{F}$, usually a large contributor on CFAs - and minimizes the resistor's thermal noise contribution ( $4 \mathrm{KTR}_{\mathrm{F}}$ ). Figure 1 details the HFA1105 broadband noise performance in its recommended configuration of $A_{V}=+2$, and $R_{F}=510 \Omega$. Adding a Comp pin to the HFA1105 (thereby creating the HFA1106) yields the 23\% noise reduction shown in Figure 2. In both cases, the scope bandwidth, 100 MHz , limits the measurement range to prevent amplifier bandwidth differences from affecting the results.

FIGURE 1. HFA1105 NOISE PERFORMANCE, $A_{V}=+2$, $R_{F}=510 \Omega$

FIGURE 2. HFA1106 NOISE PERFORMANCE, UNCOMPENSATED, $A_{V}=+2, R_{F}=100 \Omega$

## Offset Advantage

An added advantage of the lower value $R_{F}$ is a smaller DC output offset. The op amp's inverting input bias current (l $\mathrm{l}_{\mathrm{BI}}$ ) flows through the feedback resistor and generates an offset voltage error defined by:
$V_{E}=I_{B I} \times R_{F}$; and $V_{O S}=A_{V}\left( \pm V_{I O}\right) \pm V_{E}$
Reducing $R_{F}$ reduces these errors.

## Bandwidth Limiting

The HFA1106 bandwidth may be limited by connecting a resistor, $\mathrm{R}_{\text {COMP }}$ (required to damp the interaction between the compensation capacitor and the package parasitics), and capacitor, $\mathrm{C}_{\mathrm{COMP}}$, in series from pin 8 to GND. Typical performance characteristics for various $\mathrm{C}_{\text {COMP }}$ values are listed in the specification table. The HFA1106 is already unity gain stable, so the main reason for limiting the bandwidth is to reduce the broadband noise.

## Noise Advantages - Compensated

System noise reduction is maximized by limiting the op amp to the bandwidth required for the application. Noise increases as the square root of the bandwidth increase ( $4 x$ bandwidth increase yields $2 x$ noise increase), so eliminating excess
bandwidth significantly reduces system noise. Figure 3 illustrates the noise performance of the HFA1106 with its bandwidth limited to 40 MHz by a $10 \mathrm{pF} \mathrm{C}_{\text {COMP }}$. As expected the noise decreases by approximately $37 \%(100 \% \times(1-\sqrt{40 \mathrm{MHz} / 100 \mathrm{MHz}})$ ) compared with Figure 2. The decrease is an even more dramatic $48 \%$ versus the HFA1105 noise level in Figure 1.

FIGURE 3. HFA1106 NOISE PERFORMANCE, COMPENSATED, $A_{V}=+2, R_{F}=100 \Omega, C_{C}=10 \mathrm{PF}$

Additionally, compensating the HFA1106 allows the use of a lower value $R_{F}$ for a given gain. The decreased bandwidth due to $\mathrm{C}_{\text {COMP }}$ keeps the amplifier stable by offsetting the increased bandwidth from the lower $R_{F}$. As noted previously, a lower value $R_{F}$ provides the double benefit of reduced DC errors and lower total noise.

## Less Lot-to-Lot Variability

External compensation provides another advantage by allowing designers to set the op amp's performance with a precision external component. On-chip compensation capacitors can vary by $10-20 \%$ over the process extremes. A precise external capacitor dominates the on-chip compensation for consistent lot-to-lot performance and more robust designs. Compensating high frequency amplifiers to lower bandwidths can simplify design tasks and ensure long term manufacturability.

## PC Board Layout

This amplifier's frequency response depends greatly on the care taken in designing the PC board. The use of low inductance components such as chip resistors and chip capacitors is strongly recommended, while a solid ground plane is a must!

Attention should be given to decoupling the power supplies. A large value $(10 \mu \mathrm{~F})$ tantalum in parallel with a small value $(0.1 \mu \mathrm{~F})$ chip capacitor works well in most cases.

Terminated microstrip signal lines are recommended at the device's input and output connections. Capacitance, parasitic or planned, connected to the output must be minimized, compensated for by increasing $\mathrm{C}_{\mathrm{COMP}}$, or isolated by a series output resistor.

Care must also be taken to minimize the capacitance to ground at the amplifier's inverting input (-IN), as this capacitance causes gain peaking, pulse overshoot, and if large
enough, instability. To reduce this capacitance, the designer should remove the ground plane under traces connected to -IN , and keep connections to -IN as short as possible.
An example of a good high frequency layout is the Evaluation Board shown in Figure 4.

## Evaluation Board

The performance of the HFA1106 may be evaluated using the HFA11XX Evaluation Board.
Figure 4 details the evaluation board layout and schematic. Connecting $\mathrm{R}_{\mathrm{COMP}}$ and $\mathrm{C}_{\text {COMP }}$ in series from socket pin 8 to the GND plane compensates the op amp. Cutting the trace from pin 8 to the $\mathrm{V}_{\mathrm{H}}$ connector removes the stray parallel capacitance, which would otherwise affect the evaluation. Additionally, the $500 \Omega$ feedback and gain setting resistors should be changed to the proper value for the gain being evaluated.

To order evaluation boards (part number HFA11XXEVAL), please contact your local sales office.
