

FEATURES

- Excellent TCV_{OS} Match: $2 \mu V/^{\circ}C$ Max
- Low Input Offset Voltage: $150 \mu V$ Max
- Low Supply Current: $100 \mu A$
- Single-Supply Operation: $5 V$ to $30 V$
- Low Input Offset Voltage Drift: $0.75 \mu V/^{\circ}C$ Max
- High Open-Loop Gain: $2,000 V/mV$
- High PSRR: $3 \mu V/V$
- Low Input Bias Current: $12 nA$
- Wide Common-Mode Voltage Range: $V-$ to Within $1.5 V$ of $V+$
- Pin Compatible with 1458, LM158, and LM2904
- Available in Die Form

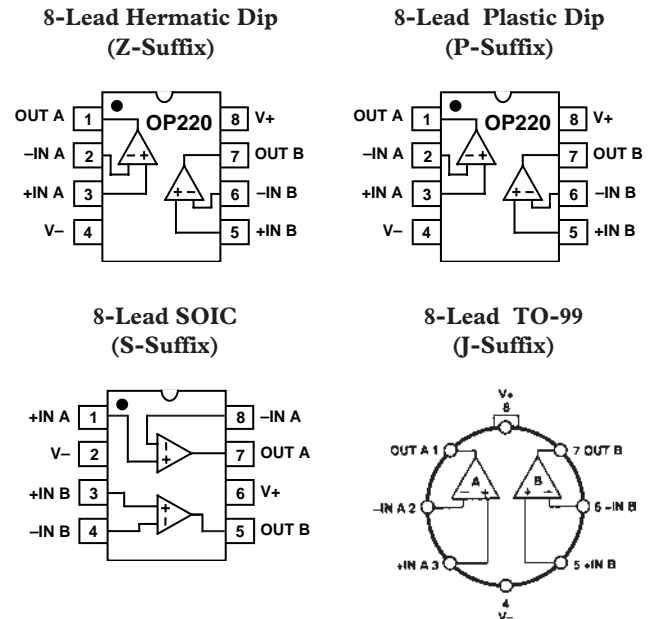

GENERAL DESCRIPTION

The OP220 is a monolithic dual operational amplifier that can be used either in single or dual supply operation. The low offset voltage and input offset voltage tracking as low as $1.0 \mu V/^{\circ}C$, make this the first micropower precision dual operational amplifier.

The excellent specifications of the individual amplifiers combined with the tight matching and temperature tracking between channels provides high performance in instrumentation amplifier designs. The individual amplifiers feature extremely low input offset voltage, low offset voltage drift, low noise voltage, and low bias current. They are fully compensated and protected.

Matching between channels is provided on all critical parameters including input offset voltage, tracking of offset voltage versus temperature, noninverting bias currents, and common-mode rejection ratios.

INSTRUMENTATION AMPLIFIER APPLICATIONS OF THE OP220

Two Op Amp Configuration

The excellent input characteristics of the OP220 make it ideal for use in instrumentation amplifier configurations where low-level differential signals are to be amplified. The low-noise, low input offsets, low drift, and high gain combined with excellent CMRR provide the characteristics needed for high-performance instrumentation amplifiers. In addition, the power supply current drain is very low.

The circuit of Figure 4 is recommended for applications where the common-mode input range is relatively low and differential gain will be in the range of 10 to 1,000. This two op amp instrumentation amplifier features independent adjustment of common-mode rejection and differential gain. Input impedance is very high since both inputs are applied to noninverting op amp inputs.

$$V_O = \frac{R4}{R3} \left[1 + \frac{1}{2} \left(\frac{R2}{R1} + \frac{R3}{R4} \right) + \frac{R2 + R3}{R0} \right] V_D + \frac{R4}{R3} \left(\frac{R3}{R4} - \frac{R2}{R1} \right) V_{CM}$$

If $R1 = R2 = R3 = R4$, then $V_O = 2 \left(1 + \frac{R1}{R0} \right) V_D$

Figure 4. Two Op Amp Instrumentation Amplifier Configuration

The input voltages are represented as a common-mode input V_{CM} plus a differential input V_D . The ratio $R3/R4$ is made equal to the ratio $R2/R1$, to reject the common-mode input V_{CM} . The differential signal V_D is then amplified according to:

$$V_O = \frac{R4}{R3} \left(1 + \frac{R3}{R4} + \frac{R2 + R3}{R0} \right) V_D, \text{ where } \frac{R3}{R4} = \frac{R2}{R1}$$

Note that gain can be independently varied by adjusting R_0 . From considerations of dynamic range, resistor tempco matching, and matching of amplifier response, it is generally best to make R_X, R_2, R_3 , and R_4 approximately equal. Designating R_1, R_2, R_3 , and R_4 as R_N allows the output equation to be further simplified:

$$V_O = 2 \left(1 + \frac{R_N}{R_0} \right) V_D, \text{ where } R_N = R_1 = R_2 = R_3 = R_4$$

Dynamic range is limited by A1 as well as A2; the output of A1 is:

$$V1 = - \left(1 + \frac{R_N}{R_0} \right) V_D + 2 V_{CM}$$

If the instrumentation amplifier were designed for a gain of 10 and maximum V_D of ± 1 V, then R_N/R_0 would need to be four and V_O would be a maximum of ± 10 V. Amplifier A1 would have a maximum output of ± 5 V plus $2 V_{CM}$, thus a limit of ± 10 V on the output of A1 would imply a limit of ± 2.5 V on V_{CM} .

A nominal value of 100 kΩ for R_N is suitable for most applications. A range of 200 Ω to 25 kΩ for R_0 will then provide a gain range of 10 to 1,000. The current through R_0 is V_D/R_0 , so the amplifiers must supply ± 10 mV/200 Ω when the gain is at the maximum value of 1,000 and V_D is at ± 10 mV.

Rejecting common-mode inputs is most important in accurately amplifying low-level differential signals. Two factors determine the CMR of this instrumentation amplifier configuration (assuming infinite gain):

1. CMRR of the op amps
2. Matching of the resistor network ($R3/R4 = R2/R1$)

In this instrumentation amplifier configuration, error due to CMRR effect is directly proportional to the differential CMRR of the op amps. For the OP220A/E, this combined CMRR is a minimum of 98 dB. A combined CMRR value of 100 dB and common-mode input range of ± 2.5 V indicates a peak input-referred error of only ± 25 μ V.

Resistor matching is the other factor affecting CMRR. Defining A_D as the differential gain of the instrumentation amplifier and assuming that R_1 , R_2 , R_3 and R_4 are approximately equal (R_N will be the nominal value), then CMRR will be approximately A_D divided by $4\Delta R/R_N$. CMRR at differential gain of 100 would be 88 dB with resistor matching of 0.1%. Trimming R_1 to make the ratio R_3/R_4 equal to R_2/R_1 will directly raise the CMRR until it is limited by linearity and resistor stability considerations.

The high open-loop gain of the OP220 is very important in achieving high accuracy in the two-op-amp instrumentation amplifier configuration. Gain error can be approximated by:

$$\text{Gain Error} = \frac{1}{1 + \frac{A_D}{A_{02}}}, \frac{A_D}{2A_{01}A_{02}} < 1$$

where A_D is the instrumentation amplifier differential gain and A_{02} is the open-loop gain of op amp A2. This analysis assumes equal values of R_1 , R_2 , R_3 , and R_4 . For example, consider an OP220 with A_{02} of 700 V/mV. If the differential gain A_D were set to 700, the gain error would be 1/1.001 which is approximately 0.1%.

Another effect of finite op amp gain is undesired feedthrough of common-mode input. Defining A_{01} as the open-loop gain of op amp A1, then the common-mode error (CME) at the output due to this effect will be approximately:

$$\text{CME} = \frac{2A_D}{1 + \frac{A_D}{A_{01}}} \frac{1}{A_{01}} V_{CM}$$

For $A_D/A_{01} < 1$, this simplifies to $(2A_D/A_{01}) \times V_{CM}$. If the op amp gain is 700 V/mV, V_{CM} is 2.5 V, and A_D is set to 700, then the error at the output due to this effect will be approximately 5 mV.

The OP220 offers a unique combination of excellent dc performance, wide input range, and low supply current drain that is particularly attractive for instrumentation amplifier design.

THREE OP AMP CONFIGURATION

A three op amp instrumentation amplifier configuration using the OP220 and OP777 is recommended for applications requiring high accuracy over a wide gain range. This circuit provides excellent CMR over a wide input range. As with the two op amp instrumentation amplifier circuits, tight matching of the two op amps provides a real boost in performance.

Figure 5. Three Op Amp Instrumentation Amplifier Using OP220 and OP777

A simplified schematic is shown in Figure 2. The input stage (A1 and A2) serves to amplify the differential input V_D without amplifying the common-mode voltage V_{CM} . The output stage then rejects the common-mode input. With ideal op amps and no resistor matching errors, the outputs of each amplifier will be:

$$V_1 = -\left(1 + \frac{2R_1}{R_O}\right) \frac{V_D}{2} + V_{CM}$$

$$V_2 = \left(1 + \frac{2R_1}{R_O}\right) \frac{V_D}{2} + V_{CM}$$

$$V_O = V_2 - V_1 = \left(1 + \frac{2R_1}{R_O}\right) V_D$$

$$V_O = A_D V_D$$

The differential gain A_D is $1 + 2R_1/R_O$ and the common-mode input V_{CM} is rejected.

This three op amp instrumentation amplifier configuration using an OP220 at the input and an OP777 at the output provides excellent performance over a wide gain range with very low power consumption. A gain range of 1 to 2,000 is practical and CMR of over 120 dB is readily achievable.
