

DESCRIPTION

The HY62256B is a high-speed, low power and 32,786 X 8-bits CMOS Static Random Access Memory fabricated using Hyundai's high performance CMOS process technology. It is suitable for use in low voltage operation and battery back-up application. This device has a data retention mode that guarantees data to remain valid at the minimum power supply voltage of 2.0 volt.

FEATURES

- Fully static operation and Tri-state output
- TTL compatible inputs and outputs
- Low power consumption
- Battery backup(L/LL-part)
 - 2.0V(min.) data retention
- Standard pin configuration
 - 28 pin 600 mil PDIP
 - 28 pin 330mil SOP
 - 28 pin 8x13.4 mm TSOP-I
 (Standard and Reversed)

TIMING DIAGRAM

READ CYCLE 1

1. tCHZ and tOHZ are defined as the time at which the outputs achieve the open circuit conditions and are not referenced to output voltage levels.
2. At any given temperature and voltage condition, tCHZ max. is less than tCLZ min. both for a given device and from device to device.
3. /WE is high for the read cycle.

1. /WE is high for the read cycle.
2. Device is continuously selected /CS= V_{IL}.
3. /OE =V_{IL}.

The diagram illustrates the timing relationships for a memory device. The signals and their timing parameters are as follows:

- ADDR**: Address bus signal. The total duration of the address is t_{WC} (Write Cycle).
- OE**: Output Enable signal. It is active-low (indicated by a bar over the symbol). It is shown in a high-impedance state (hatched) when not active.
- CS**: Chip Select signal. It is active-low. The duration of the active period is t_{AW} (Access Width).
- WE**: Write Enable signal. It is active-low. The duration of the active period is t_{CW} (Write Cycle Width).
- Data In**: Data bus signal for writing. The data is valid for a duration of t_{AS} (Access Setup) before the write operation begins.
- Data Out**: Data bus signal for reading. The data is valid for a duration of t_{WP} (Write Period) after the write operation begins.
- Timing Parameters**:
 - t_{WR} : Write Recovery time, the time from the end of the write operation to the start of the next read operation.
 - t_{OHZ} : Output Hold time, the time from the end of the write operation to the start of the next read operation.
 - t_{DW} : Data Valid time, the time from the start of the write operation to the start of the next read operation.
 - t_{DH} : Data Hold time, the time from the end of the write operation to the end of the next read operation.

WRITE CYCLE 2 (/OE Low Fixed)

Notes(WRITE CYCLE):

1. A write occurs during the overlap of a low /CS and a low /WE. A write begins at the latest transition among /CS going low and /WE going low. A write ends at the earliest transition among /CS going high and /WE going high. tWP is measured from the beginning of write to the end of write.
2. tcw is measured from the later of /CS going low to the end of write .
3. tAS is measured from the address valid to the beginning of write.
4. tWR is measured from the end of write to the address change. tWR is applied in case a write ends as /CS, or /WE going high.
5. If /OE and /WE are in the read mode during this period, and the I/O pins are in the output low-Z state, input of opposite phase of the output must not be applied because bus contention can occur.
6. If /CS goes low simultaneously with /WE going low, or after /WE going low, the outputs remain in high impedance state.
7. DOUT is the same phase of the latest written data in this write cycle.
8. DOUT is the read data of the new address.
