

**Features**

- Complete variable-gain amplifier with output amplifier, requires no extra components
- Excellent linearity of 0.2%
- 70 MHz signal bandwidth
- Operates on  $\pm 5V$  to  $\pm 15V$  supplies
- All inputs are differential
- 400V/ $\mu s$  slew rate
- >70dB attenuation @ 4 MHz

**Applications**

- Leveling of varying inputs
- Variable filters
- Fading
- Text insertion into video

**Ordering Information**

Part No.	Temp. Range	Package	Outline #
EL4451CN	-40°C to +85°C	14-Pin P-DIP	MDP0031
EL4451CS	-40°C to +85°C	14-Lead SO	MDP0027

**General Description**

The EL4451C is a complete variable gain circuit. It offers wide bandwidth and excellent linearity while including a powerful output voltage amplifier, drawing modest supply current.

The EL4451C operates on  $\pm 5V$  to  $\pm 15V$  supplies and has an analog input range of  $\pm 2V$ , making it ideal for video signal processing. AC characteristics do not change appreciably over the  $\pm 5V$  to  $\pm 15V$  supply range.

The circuit has an operational temperature range of  $-40^\circ C$  to  $+85^\circ C$  and is packaged in plastic 14-pin DIP and 14-lead SO.

The EL4451C is fabricated with Elantec's proprietary complementary bipolar process which provides excellent signal symmetry and is free from latch up.

## Wideband Variable-Gain Amplifier, Gain of 2

### Applications Information

The EL4451 is a complete two-quadrant multiplier/gain control with 70 MHz bandwidth. It has three sets of inputs; a differential signal input  $V_{IN}$ , a differential gain-controlling input  $V_{GAIN}$ , and another differential input which is used to complete a feedback loop with the output. Here is a typical connection:

The gain of the feedback divider is

$$H = \frac{R_G}{R_G + R_F}$$

The transfer function of the part is

$$V_{OUT} = A_O \times ((V_{IN+}) - (V_{IN-})) \times ((V_{GAIN+}) - (V_{GAIN-})) + (V_{REF} - V_{FB})$$

$V_{FB}$  is connected to  $V_{OUT}$  through a feedback network, so  $V_{FB} = H \times V_{OUT}$ .  $A_O$  is the open-loop gain of the amplifier, and is approximately 600. The large value of  $A_O$  drives

$$((V_{IN+}) - (V_{IN-})) \times ((V_{GAIN+}) - (V_{GAIN-})) + (V_{REF} - V_{FB}) \rightarrow 0$$

Rearranging and substituting for  $V_{FB}$

$$V_{OUT} = (((V_{IN+}) - (V_{IN-})) \times ((V_{GAIN+}) - (V_{GAIN-})) + V_{REF})/H$$

or

$$V_{OUT} = (V_{IN} \times V_{GAIN} + V_{REF})/H$$

Thus the output is equal to the difference of the  $V_{IN}$ 's times the difference of  $V_{GAIN}$ 'S and offset by  $V_{REF}$ , all gained up by the feedback divider ratio. The EL4451 is stable for a direct connection between  $V_{OUT}$  and FB, and the divider may be used for higher output gain, although with the traditional loss of bandwidth.

It is important to keep the feedback divider's impedance at the FB terminal low so that stray capacitance does not diminish the loop's phase margin. The pole caused by the parallel impedance of the feedback resistors and stray capacitance should be at least 150 MHz; typical strays of 3 pF thus require a feedback impedance of

360 $\Omega$  or less. Alternatively, a small capacitor across  $R_F$  can be used to create more of a frequency-compensated divider. The value of the capacitor should scale with the parasitic capacitance at the FB input. It is also practical to place small capacitors across both the feedback and the gain resistors (whose values maintain the desired gain) to swamp out parasitics. For instance, two 10pF capacitors across equal divider resistors for a maximum gain of 4 will dominate parasitic effects and allow a higher divider resistance.

The REF pin can be used as the output's ground reference, for DC offsetting of the output, or it can be used to sum in another signal.

### Gain-Control Characteristics

The quantity  $V_{GAIN}$  in the above equations is bounded as  $0 \leq V_{GAIN} \leq 2$ , even though the externally applied voltages exceed this range. Actually, the gain transfer function around 0 and 2V is "soft"; that is, the gain does not clip abruptly below the 0%- $V_{GAIN}$  voltage nor above the 100%- $V_{GAIN}$  level. An overdrive of 0.3V must be applied to  $V_{GAIN}$  to obtain truly 0% or 100%. Because the 0%- or 100%-  $V_{GAIN}$  levels cannot be precisely determined, they are extrapolated from two points measured inside the slope of the gain transfer curve. Generally, an applied  $V_{GAIN}$  range of -0.5V to +2.5V will assure the full numerical span of  $0 \leq V_{GAIN} \leq 2$ .

The gain control has a small-signal bandwidth equal to the  $V_{IN}$  channel bandwidth, and overload recovery resolves in about 20 nsec.

### Input Connections

The input transistors can be driven from resistive and capacitive sources, but are capable of oscillation when presented with an inductive input. It takes about 80nH of series inductance to make the inputs actually oscillate, equivalent to four inches of unshielded wiring or 6" of unterminated input transmission line. The oscillation has a characteristic frequency of 500 MHz. Often placing one's finger (via a metal probe) or an oscilloscope probe on the input will kill the oscillation. Normal high-frequency construction obviates any such problems, where the input source is reasonably close to the input. If this is not possible, one can insert series resistors of around 51 $\Omega$  to de-Q the inputs.

# EL4451C

## Wideband Variable-Gain Amplifier, Gain of 2

### Applications Information — Contd.

#### Signal Amplitudes

Signal input common-mode voltage must be between  $(V-) + 3V$  and  $(V+) - 3V$  to ensure linearity. Additionally, the differential voltage on any input stage must be limited to  $\pm 6V$  to prevent damage. The differential signal range is  $\pm 2V$  in the EL4451. The input range is substantially constant with temperature.

#### The Ground Pin

The ground pin draws only  $6\mu A$  maximum DC current, and may be biased anywhere between  $(V-) + 2.5V$  and  $(V+) - 3.5V$ . The ground pin is connected to the IC's substrate and frequency compensation components. It serves as a shield within the IC and enhances input stage CMRR and feedthrough over frequency, and if connected to a potential other than ground, it must be bypassed.

#### Power Supplies

The EL4451 works with any supplies from  $\pm 3V$  to  $\pm 15V$ . The supplies may be of different voltages as long as the requirements of the ground pin are observed (see the Ground Pin section). The supplies should be bypassed close to the device with short leads.  $4.7\mu F$  tantalum capacitors are very good, and no smaller bypasses need be placed in parallel. Capacitors as small as  $0.01\mu F$  can be used if small load currents flow.

Single-polarity supplies, such as  $+12V$  with  $+5V$  can be used, where the ground pin is connected to  $+5V$  and  $V-$  to ground. The inputs and outputs will have to have their levels shifted above ground to accommodate the lack of negative supply.

The power dissipation of the EL4451 increases with power supply voltage, and this must be compatible with the package chosen. This is a close estimate for the dissipation of a circuit:

$$P_D = 2 \times V_S \times I_{S, \max} + (V_S - V_O) \times V_O / R_{PAR}$$

where  $I_{S, \max}$  is the maximum supply current

$V_S$  is the  $\pm$  supply voltage (assumed equal)

$V_O$  is the output voltage

$R_{PAR}$  is the parallel of all resistors loading the output

For instance, the EL4451 draws a maximum of 18mA. With light loading,  $R_{PAR} \rightarrow \infty$  and the dissipation with  $\pm 5V$  supplies is 180 mW. The maximum supply voltage that the device can run on for a given  $P_D$  and other parameters is

$$V_{S, \max} = (P_D + V_O^2 / R_{PAR}) / (2I_S + V_O / R_{PAR})$$

The maximum dissipation a package can offer is

$$P_{D, \max} = (T_{J, \max} - T_{A, \max}) / \theta_{JA}$$

Where  $T_{J, \max}$  is the maximum die temperature,  $150^\circ C$  for reliability, less to retain optimum electrical performance

$T_{A, \max}$  is the ambient temperature,  $70^\circ C$  for commercial and  $85^\circ C$  for industrial range

$\theta_{JA}$  is the thermal resistance of the mounted package, obtained from data sheet dissipation curves

The more difficult case is the SO-14 package. With a maximum die temperature of  $150^\circ C$  and a maximum ambient temperature of  $85^\circ C$ , the  $65^\circ C$  temperature rise and package thermal resistance of  $120^\circ C/W$  gives a dissipation of 542 mW at  $85^\circ C$ . This allows the full maximum operating supply voltage unloaded, but reduced if loaded.

#### Output Loading

The output stage of the EL4451 is very powerful. It typically can source 80mA and sink 120mA. Of course, this is too much current to sustain and the part will eventually be destroyed by excessive dissipation or by metal traces on the die opening. The metal traces are completely reliable while delivering the 30mA continuous output given in the Absolute Maximum Ratings table in this data sheet, or higher purely transient currents.

Gain changes only 0.2% from no load to  $100\Omega$  load. Heavy resistive loading will degrade frequency response and video distortion for loads  $< 100\Omega$ .

Capacitive loads will cause peaking in the frequency response. If capacitive loads must be driven, a small-valued series resistor can be used to isolate it.  $12\Omega$  to  $51\Omega$  should suffice. A  $22\Omega$  series resistor will limit peaking to 2.5 dB with even a 220pF load.

# EL4451C

## Wideband Variable-Gain Amplifier, Gain of 2

### Applications Information — Contd.

#### Leveling Circuits

Often a variable-gain control is used to normalize an input signal to a standard amplitude from a modest range of possible input amplitude. A good example is in video systems, where an unterminated cable will yield a twice-sized standard video amplitude, and an erroneously twice-terminated cable gives a 2/3-sized input.

Here is a  $\pm 6$  dB range preamplifier:

**Linearized Leveling Amplifier**

4451-30

In this arrangement, the EL4451 outputs a mixture of the signal routed through the multiplier and the REF terminal. The multiplier port produces the most distortion and needs to handle a fraction of an oversized video input, whereas the REF port is just like an op-amp input summing into the output. Thus, for oversized inputs the gain will be decreased and the majority of the signal is routed through the linear REF terminal. For undersized inputs, the gain is increased and the multiplier's contribution added to the output.

Here are some component values for two designs:

Attenuation Ratio	R <sub>F</sub>	R <sub>G</sub>	R <sub>1</sub>	R <sub>2</sub>	R <sub>3</sub>	-3 dB Bandwidth
1.5	200Ω	400Ω	300Ω	100Ω	200Ω	47 MHz
2	400Ω	400Ω	500Ω	100Ω	200Ω	28 MHz

4451-31

4451-32

With the higher attenuation ratio, the multiplier sees a smaller input amplitude and distorts less, however the higher output gain reduces circuit bandwidth. As seen in the next curves, the peak differential gain error is 0.47% for the attenuation ratio of 1.5, but only 0.27% with the gain of 2 constants. To maintain bandwidth, an external op amp can be used instead of the R<sub>F</sub> - R<sub>G</sub> divider to boost the EL4451's output by the attenuation ratio.

#### Sinewave Oscillators

Generating a stable, low distortion sinewave has long been a difficult task. Because a linear oscillator's output tends to grow or diminish continuously, either a clipping circuit or automatic gain control (AGC) is needed. Clipping circuits generate severe distortion which needs subsequent filtering, and AGC's can be complicated.

# EL4451C

## Wideband Variable-Gain Amplifier, Gain of 2

### Applications Information — Contd.

Here is the EL4451 used as an oscillator with simple AGC:

#### Low-Distortion Sinewave Oscillator

4451-33

The oscillation frequency is set by the resonance of a series-tuned circuit, which may be an L-C combination or a crystal. At resonance, the series impedance of the tuned circuit drops and its phase lag is  $0^\circ$ , so the EL4451 needs a gain just over unity to sustain oscillation. The  $V_{GAIN-}$  terminal is initially at  $-0.7V$  and the  $V_{GAIN+}$  terminal at about  $+2.1V$ , setting the maximum gain in the EL4451. At such high gain, the loop oscillates and output amplitude grows until  $D_1$  rectifies more positive voltage at  $V_{GAIN-}$ , ultimately reducing gain until a stable  $0.5V_{rms}$  output is produced.

Using a 2 MHz crystal, output distortion was  $-53$  dBc, or 0.22%. Sideband modulation was only 14 Hz wide at  $-90$  dBc, limited by the filter of the spectrum analyzer used.

The circuit works up to 30 MHz. A parallel-tuned circuit can replace the  $510\Omega$  resistor and the  $510\Omega$  resistor moved in place of the series-tuned element to allow grounding of the tuned components.

### Filters

The EL4451 can be connected to act as a voltage-variable integrator as shown:

#### EL4451 Connected As Variable Integrator

4451-34

The input RC cancels a zero produced by the output op-amp feedback connection at  $\omega = 1/RC$ . With the input RC connected  $V_{OUT}/V_{IN} = 1/sRC$ ; without it  $V_{OUT}/V_{IN} = (1 + sRC)/sRC$ . This variable integrator may be used in networks such as the Bi-quad. In some applications the input RC may be omitted. If a negative gain is required, the  $V_{IN+}$  and  $V_{IN-}$  terminals can be exchanged.

# EL4451C

## Wideband Variable-Gain Amplifier, Gain of 2

### Applications Information — Contd.

A voltage-controlled equalizer and cable driver can be constructed so:

#### Equalization and Line Driver Amplifier

4451-35

The main signal path is via the REF pin. This ensures maximum signal linearity, while the multiplier input is used to allow a variable amount of frequency-shaped input from  $R_1$ ,  $R_2$ , and  $C$ . For optimum linearity, the multiplier input is attenuated by  $R_1$  and  $R_2$ . This may not be necessary, depending on input signal amplitude, and  $R_1$  might be set to 0.  $R_1$  and  $R_2$  should be set to provide sufficient peaking, depending on cable high-frequency losses, at maximum gain.  $R_F$  and  $R_G$  are chosen to provide the desired circuit gain, including backmatch resistor loss.
