Product Description:

Pericom Semiconductor's PI5C series of logic circuits are produced in the Company's advanced submicron CMOS technology, achieving industry leading performance.

The PI5C3390 and PI5C32390 are 16-to-8 multiplexer/demultiplexer bus switches with a low ON resistance allowing inputs to be connected directly to outputs. The two enable inputs connect each of eight I/O to the common I/O pin. This multiplexer function can be used to select and route logic signals to form crossbar switches, isolate bus capacitance, or provide a zero delay switch connection. The bus switch creates no additional ground bounce noise or additional propagation delay. The PI5C32390 is designed with an internal 25ohm resistor reducing noise reflection in high-speed applications.

Notes:

- For Max. or Min. conditions, use appropriate value specified under Electrical Characteristics for the applicable device type.
- Typical values are at V_{CC} = 5.0V, T_A = 25°C ambient and maximum loading.
- Not more than one output should be shorted at one time. Duration of the test should not exceed one second.
- Measured by the voltage drop between A, B, and C pins at indicated current through the switch. ON resistance is determined by the lower of the voltages on the two (A,B,C) pins.
- This parameter is determined by device characterization but is not production tested.

Power Supply Characteristics

Parameters	Description	Test Conditions ⁽¹⁾		Min.	Typ ⁽²⁾	Max.	Units

Notes:

- For Max. or Min. conditions, use appropriate value specified under Electrical Characteristics for the applicable device.
- Typical values are at V_{CC} = 5.0V, +25°C ambient.
- Per TTL driven input (V_{IN} = 3.4V, control inputs only); A, B, and C pins do not contribute to I_{CC}.
- This current applies to the control inputs only and represent the current required to switch internal capacitance at the specified frequency. The A, B, and C inputs generate no significant AC or DC currents as they transition. This parameter is not tested, but is guaranteed by design.
- Values for these conditions are examples of the I_{CC} formula. These limits are guaranteed but not tested.

			Com			
			Min.	Typ.	Max.	
tPLH tPHL	Propagation Delay ^(2,3) A, B to/from C	CL = 50 pF RL = 500ohm	—	1.25	—	ns

tPHZ tPLZ	Bus Disable Time AEN/BEN to A, B, C		1.5	—	5.5	ns

Notes:

- See test circuit and waveforms.
- This parameter is guaranteed but not tested on Propagation Delays.
- The bus switch contributes no propagational delay other than the RC delay of the ON resistance of the switch and the load capacitance. The time constant for the switch alone is of the order of 0.25 ns for 50 pF load. Since this time constant is much smaller than the rise/fall times of typical driving signals, it adds very little propagational delay to the system. Propagational delay of the bus switch when used in a system is determined by the driving circuit on the driving side of the switch and its interaction with the load on the driven side.
