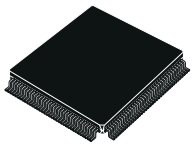
STLC60135

TOSCA™ ADSL DMT TRANSCEIVER

- DTM modem for ADSL, compatible with the following standards:
  - ANSI T1.413 Issue 2
  - ITU-T G.992.1 (G.dmt)
  - ITU-T G.992.2 (G.lite)
- Same chip for both ATU-C and ATU-R
- Supports either ATM (Utopia level 1 & 2) or bit-stream interface
- 16 bit multiplexed microprocessor interface (little and big endian compatibility)
- Analog Front End management
- Dual latency paths: fast and interleaved
- ATM's PHY layer: cell processing (cell delineation, cell insertion, HEC)
- ADSL's overhead management
- Reed Solomon encode/decode
- Trellis encode/decode (Viterbi)
- DMT mapping/ demapping over 256 carriers
- Fine (2ppm) timing recover using Rotor and Adaptative Frequency Domain Equalizing
- Time Domain Equalization
- Front end digital filters
- 0.35µm HCMOS6 Technology
- 144 pin PQFP package
- Power Consumption 1 Watt at 3.3V



PQFP144

ORDERING NUMBER: STLC60135

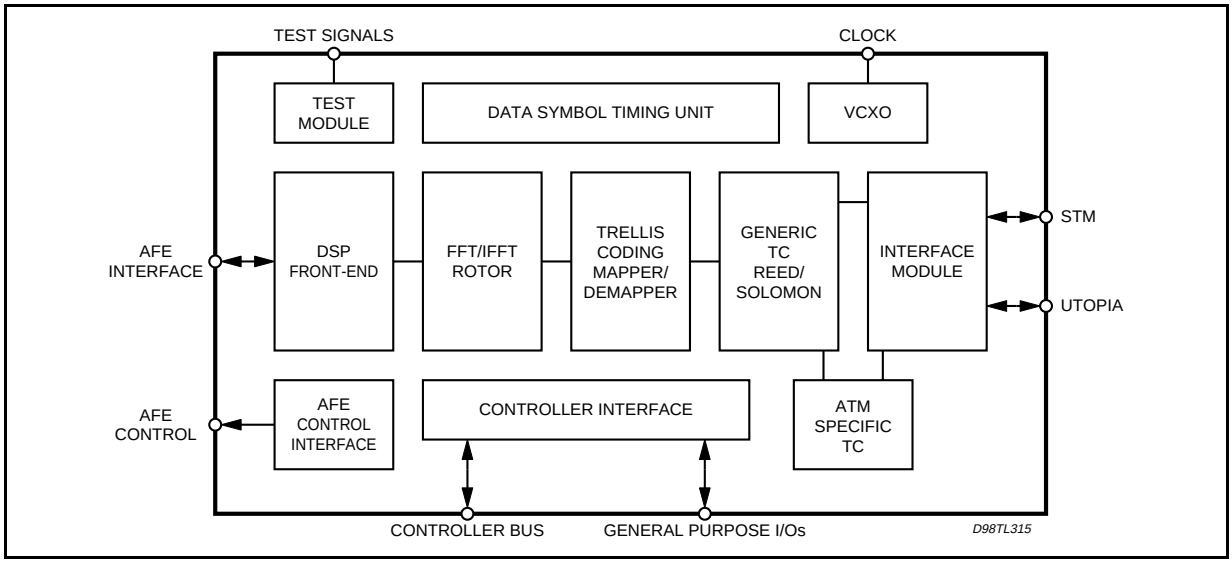
Applications

- **ATU-C:** DSLAM, Routers at Central Office
- **ATU-R:** Routers at SOHO, stand-alone modems, PC mother boards

General Description

The STLC60135 is the DMT modem and ATM framer of the STMicroelectronics Tosca™ chipset. When coupled with STLC60134 analog front-end and an external controller running dedicated firmware, the product fulfils ANSI T1.413 "Issue 2" DMT ADSL specification.
The STLC60135 may be used at both ends of ADSL loop: ATU-C and ATU-R. The chip supports UTOPIA level 1 and UTOPIA level 2 interface and a non ATM synchronous bit-stream interface.

Figure 1. Block Diagram



The STLC60135 can be splitted up into two different sections. The physical one performs the DMT modulation, demodulation, Reed-Solomon encoding, bit interleaving and 4D trellis coding.

The ATM section embodies framing functions for the generic and ATM Transmission Convergence (TC) layers. The generic TC consists of data scrambling and Reed Solomon error corrections, with and without interleaving.
The STLC60135 is controlled and programmed by an external controller (ADSL Transceiver Controller, ATC) that sets the programmable coefficients.
The firmware controls the initialization phase and carries out the consequent adaptation operations.

Transient Energy Capabilities

ESD

ESD (Electronic Discharged) tests have been performed for the Human Body Model (HBM) and for the Charged Device Model (CDM).
The pins of the device are to be able to withstand minimum 1500V for the HBM and minimum 250V for CDM.

Latch-up

The maximum sink or source current from any pin is limited to 100mA to prevent latch-up.

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Min	Typ	Max	Unit
V_{DD}	Supply Voltage	3.0	3.3	3.6	V
P_{tot}	Total Power Dissipation		900	1400	mW
T_{amb}	Ambient Temperature 1m/s airflow	-40		85	°C

B = Bidirectional cell
C = Clock

Main Block Description

The following drawings describe the sequence of functions performed by the chip.

DSP Front-End

The DSP Front-End contains 4 parts in the receive direction: the Input Selector, the Analog Front-End Interface, the Decimator and the Time Equalizer. The input selector is used internally to enable test loopbacks inside the chip. The Analog Front-End Interface transfers 16-bit words, multiplexed on 4 input/output signals. Word transfer is carried out in 4 clock cycles.

The Decimator receive 16-bits samples at 8.8 MHz (as sent by the Analog Front-End chip: STLC60134) and reduces this rate to 2.2 MHz.

The Time Equalizer (TEQ) module is a FIR filter with programmable coefficients. Its main purpose is to reduce the effect of Inter-Symbol Interferences (ISI) by shortening the channel impulse response.

Both the Decimator and TEQ can be bypassed.

In the transmit direction, the DSP Front-End includes: sidelobe filtering, clipping, delay equalization and interpolation. The sidelobe filtering and delay equalization are implemented by IIR Filters, reducing the effect of echo in FDM systems. Clipping is a statistical process limiting the amplitude of the output signal, optimizing the dynamic range of the AFE. The interpolator receives data at 2.2 MHz and generates samples at a rate of 8.8 MHz.

DMT Modem

This module is a programmable DSP unit. Its instruction set enables the basic functions of the DMT algorithm like FFT, IFFT, Scaling, Rotor and Frequency Equalization (FEQ) in compliance with ANSI T1.413 specifications.

In the RX path, the 512-point FFT transforms the time-domain DMT symbol into a frequency domain representation which can be further decoded by the subsequent demapping stages.

In other words, the Fast Fourier Transform process is used to transform from time domain to frequency domain (receive path). On ATU-C side, 128 time samples are processed. On ATU-R side, 1024 time samples are processed.

After the first stage time domain equalization and FFT block an ICI (InterCarrier Interference) free information stream turns out.

Figure 3. DSP Front-End Receive

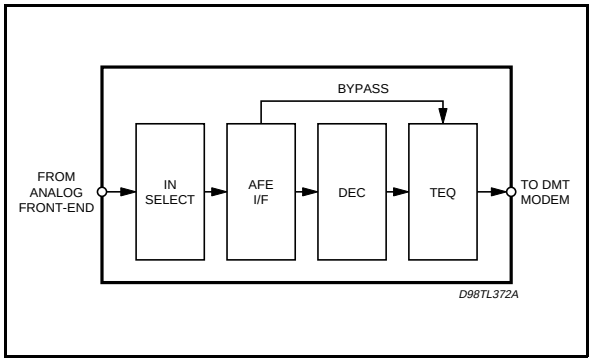

Figure 4. DSP Front-End Transmit

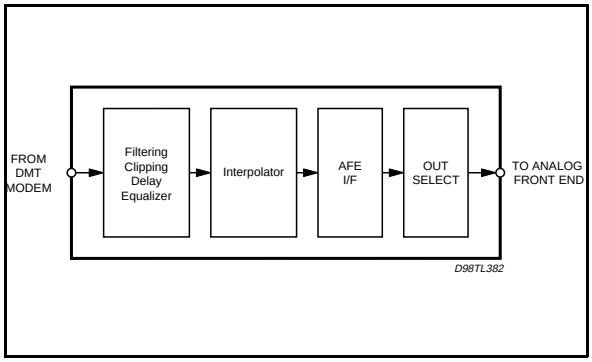

Figure 5. DMT Modem (Rx & Tx)

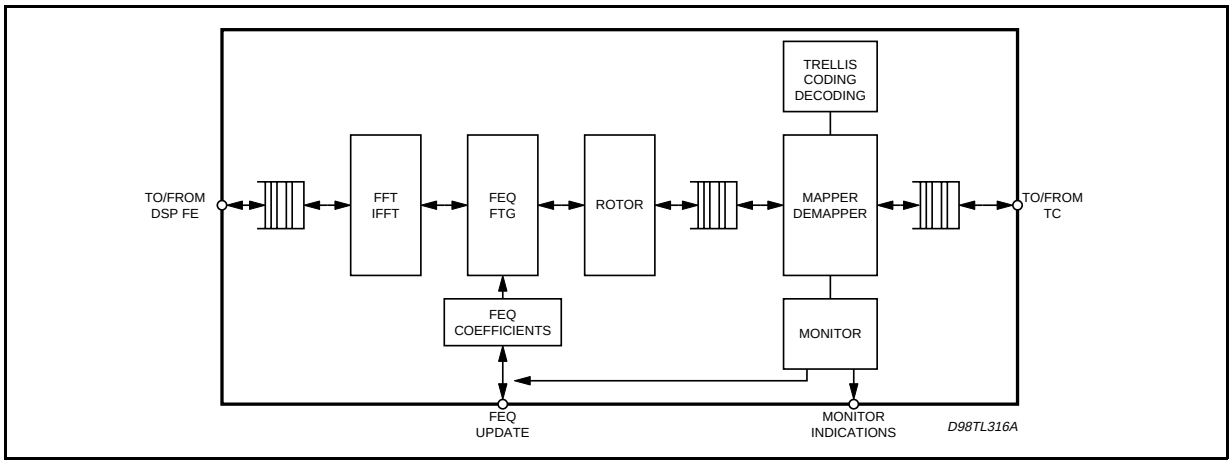


This stream is still affected by carrier specific channel distortion resulting in an attenuation of the signal amplitude and a rotation of the signal phase. To compensate, a Frequency domain equalizer (FEQ) and a Rotor (phase shifter) are implemented. The frequency domain equalisation performs an operation on the received vector in order to match it with the associated point in the constellation. The coefficient used to perform the equalisation are floating point, and may be updated by hardware or software, using a mechanism of active and inactive table to avoid DMT synchro problems.
In the transmit path, the IFFT reverses the DMT symbol from frequency domain to time domain.

The IFFT block is preceded by Fine Tune Gain (FTG) and Rotor stages, allowing for a compensation of the possible frequency mismatch between the master clock frequency and the transmitter clock frequency (which may be locked to another reference).

The Inverse Fast Fourier Transform process is used to transform from frequency domain to time domain (transmit path). On ATU-C side, 512 frequencies are processed, giving 1024 samples in the time domain. On ATU-R side, 256 positive frequencies are processed, giving 512 samples in the time domain.

The FFT module is a slave DSP engine controlled by the firmware running on an external controller. It works off line and communicates with other blocks through buffers controlled by the “Data Symbol Timing Unit”. The DSP executes a program stored in a RAM area, which constitutes a flexible element that allows for future system enhancements.

DPLL

The Digital PLL module receives a metric for the phase error of the pilot tone. In general, the clock frequencies at the ends (transmitter and receiver) do not match exactly. The phase error is filtered and integrated by a low pass filter, yielding an estimation of the frequency offset. Various processes can use this estimate to deal with the frequency mismatch.

In particular, small accumulated phase error can be compensated in the frequency domain by a rotation of the received code constellation (Rotor). Larger errors are compensated in the time domain by inserting or deleting clock cycles in the sample input sequence.

Eventually that leads to achieve less than 2ppm between the two ends.

Mapper/Demapper, Monitor, Trellis Coding, FEQ Update

The Demapper converts the constellation points computed by the FFT to a block of bits. This means to identify a point in a 2D QAM constellation plane. The Demapper supports Trellis coded demodulation and provides a Viterbi maximum likelihood estimator. When the Trellis is active, the Demapper receives an indication for the most likely constellation subset to be used.

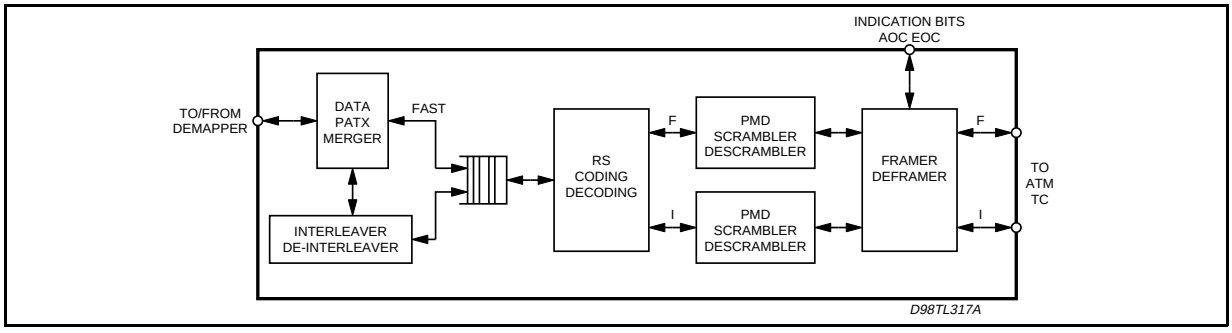
In the transmit direction, the mapper receives a bit stream from the Trellis encoder and modulates the bit stream on a set of carriers (up to 256). It generate coordinates for 2n QAM constellation, where n < 15 for all carriers.

The Mapper performs the inverse operation, mapping a block of bits into one constellation point (in a complex x+jy representation) which is passed to the IFFT block. The Trellis Encoder generates redundant bits to improve the robustness of the transmission, using a 4-Dimensional Trellis Coded Modulation scheme. This feature can be disabled.
The Monitor computes error parameters for carriers specified in the Demapper process. Those parameters can be used for updates of adaptive filters coefficients, clock phase adjustments, error detection,etc. A series of values is constantly monitored, such as signal power, pilot phase deviations, symbol erasures generation, loss of frame,etc.

Generic TC Layer Functions

These functions relate to byte oriented data streams. They are completely described in ANSI T 1.4 13. Additions described in the Issue 2 of

Figure 6. Generic TC Layer Functions



this specification are also supported.
The data received from the demapper may be split into two paths, one dedicated to an interleaved data flow the other one for a fast data flow. No external RAM is needed for the interleaved path.
The interleaving/deinterleaving is used to increase the error correcting capability of block codes for error bursts. After deinterleaving (if applicable), the data flow enters a Reed-Solomon error correcting code decoder, able to correct a number of bytes containing bit errors. The decoder also uses the information of previous receiving stages that may have detected the errored bytes and have labelled them with an “erasure” indication”.
Each time the RS decoder detects and corrects errors in a RS codeword, an RS correction event is generated. The occurrence of such events can be signalled to the management layer.
After the RS decoder, the corrected byte stream is descrambled in the PMD (Physical Medium Dependent) descramblers.
Two descramblers are used, for interleaved and non-interleaved data flows.
These are defined in ANSI T1.413.
After descrambling, the data flows enter the Deframer that extracts and processes bytes to support Physical layer related functions according to ANSI T1.413. The ADSL frames indeed contain physical layer-related information in addition to the data passed to the higher layers. In particular, the deframer extracts the EOC (Embedded Operations Channel), the AOC (ADSL Overhead Control) and the indicators bits and passes them to the appropriate processing unit (e.g. the transceiver controller). The deframer also performs a CRC check (Cyclic Redundancy Check) on the received frame and generates events in case of error detection.
Event counters can be read by management processes. The outputs of the deframer are an interleaved and a fast data streams.
These data streams can either carry ATM cells or another type of traffic. In the latter case, the ATM specific TC layer functional block, described hereafter, is bypassed and the data stream is directly presented at the input of the interface module.

ATM Specific TC Layer Functions

The 2 bytes streams (fast and slow) are received from the byte-based processing unit. When ATM cells are transported, this block provides basic cell functions such as cell synchronization, cell payload descrambling, idle/unassigned cell filter, cell Header Error Correction (HEC) and detection. The cell processing happens according to ITU-T I.163 standard. Provision is also made for BER measurements at this ATM cell level. When non cell oriented byte streams are transported, the cell processing unit is not active. The interface

Figure 7. ATM Specific TC Layer Functions

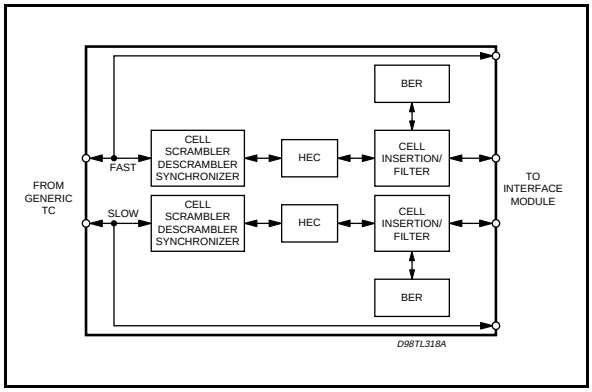


Figure 8. Interface Module

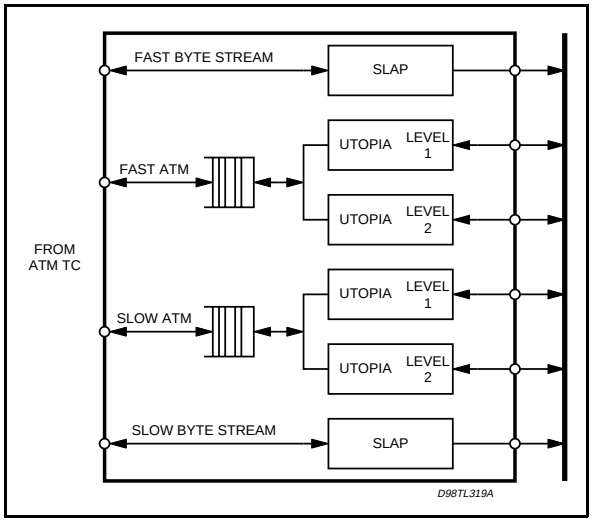


module collects cells (from the cell-based function module) or a Byte stream (from the deframer). Cells are stored in FIFO’s (424 bytes or 8 cell wide, transmit buffers have the same size), from which they are extracted by 2 interface submodules, one providing a Utopia level 1 interface and the other a Utopia level 2 interface.
Byte stream are dumped on the SLAP (Synchronous Link Access Protocol) interface.
Only one type of interface can be enabled in a specific configuration.

DMT Symbol Timing Unit (DSTU)

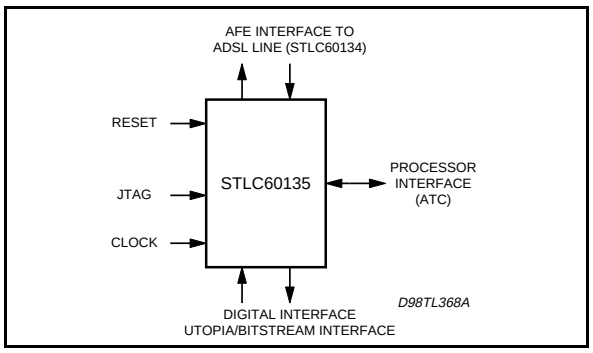
The DSTU interfaces with various modules, like DSP FrontEnd, FFT/IFFT, Mapper/Demapper, RS , Monitor and Transceiver Controller. It consists of a real time and a scheduler modules. The real time unit generate a timebase for the DMT symbols (sample counter), superframes (symbol counter) and hyper-frames (sync counter). The timebases can be modified by various control features. They are continuously fine-tuned by the DPLL module.

The DSTU schedulers execute a program, controlled by program opcodes and a set of variables, the most important of which are real time counters. The transmit and receive sequencers are completely independent and run different programs. An independent set of variables is assigned to each of them. The sequencer programs can be updated in real time.

STLC60135 interfaces

■ Overview

Figure 9. STLC60135 interfaces



■ Processor Interface (ATC)

The STLC60135 is controlled and configured by an external processor across the processor interface. All programmable coefficients and parameters are loaded through this path.

The ADSL initialization is also controlled by this interface

Two interface types are supported; A generic asynchronous interface (i.e. PowerPC or any microprocessor interface) and a specific i960 interface. The choice is made by the OBC_TYPE pin. (0 selects i960 type interface, 1 selects generic access).

Data and addresses are multiplexed.

STLC60135 works in 16 bits data access, so address bit 0 is not used. Address bit 1 is not multiplexed with data. It has its own pin : BE1

Byte acces are not supported. Access cycle read or write are always in 16 bits data wide, ie bit address A0 is always zero value. The interrupt request pin to the processor is INTB, and is an Open Drain output.

Tle STLC60135 supports both little and big endian. The default feature is big endian.

Figure 10. Processor Interface Read cycle i960 mode

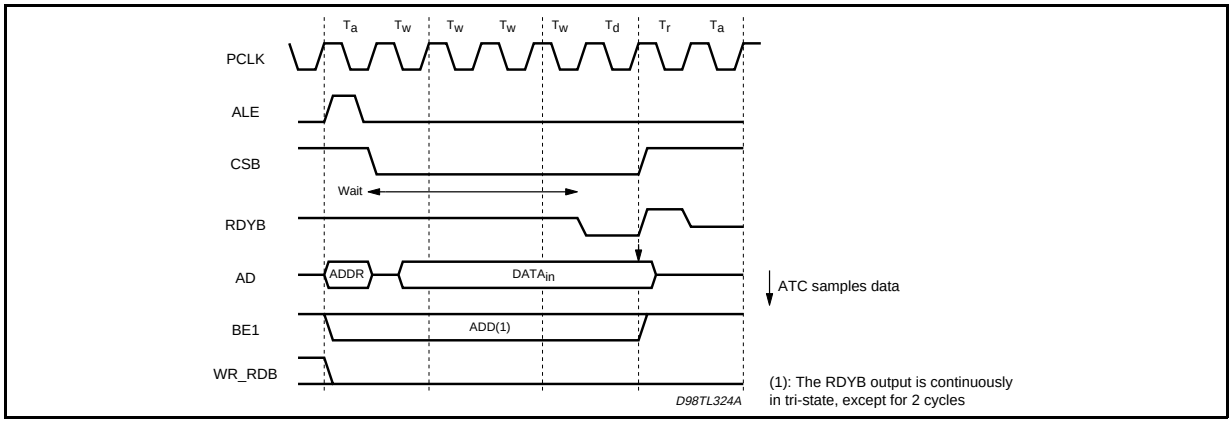


Figure 11. Processor Interface Write Cycle i960 mode

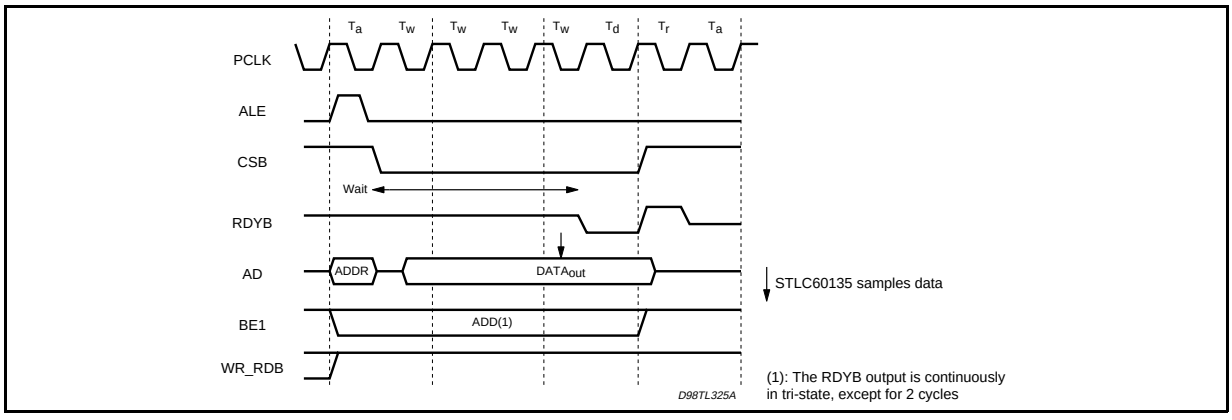

The processor interface in i960 mode

The i960 mode supports a synchronous bus interface protocol.
Address and data are multiplexed. The processor is bus master and the STLC60135 is bus slave.
Synchronous means that all signals are synchronous with the input clock PCLK pin.

The bus cycles are directly started and driven by the processor. Addresses (BE1, AD[2..15]) have to be present before ATC asserts the ALE signal.

STLC60135 latches the address on the falling edge of ALE signal.
The RDYB output is synchronous to PCLK.

A bus cycle consists of an Access cycle (Ta), Wait cycles (Tw), Data cycle (Td) and Recovery cycle (Tr).

Processor Interface Pins and Functional Description i960 mode

Name	Type	Function
AD[0...15]	I/O	Multiplexed Address/Data bus
BE1	I	Address bit 1
ALE	I	Address Latch Enable
WR_RDB	I	Access direction: Write (1), Read (0)
PCLK	I	Processor Clock
CSB	I	Chip Select
RDYB	OZ	Bus cycle ready indication
INTB	O	Interrupt

Generic Interface

This interface is suitable for a number of processors using a multiplexed Address/data bus. In this case, synchronisation of the input signals with PCLK pin is not necessary.

■ Digital interface ATM or serial

Digital Interface for data to the loop before modulation and from the loop after demodulation.

This interface collects cells (from the cell based function module) or a byte stream (from the deframer). Cells are stored in a fifo, 2 interfaces submodules can extract data from the fifo. Byte streams are dumped on the bitstream interface (with no fifo).

3 kinds of interface are allowed

- Utopia Level 1
- Utopia Level 2
- Bitstream based on a proprietary exchange

The interface selection is programmed by writing the Utopia PHY address register.

Only one interface can be enabled in a ST60135 configuration.

Utopia Level 1 supports only one PHY device. Utopia Level 2 supports multi-PHY devices (See Utopia Level 2 specifications).

Each buffer provides storage for 8 ATM cells (both directions for Fast and Interleaved channel).

The Utopia Level 2 supports point to multipoint configurations by introducing an addressing capability and by making distinction between polling and selecting a device.

Figure 15. Receive Interface

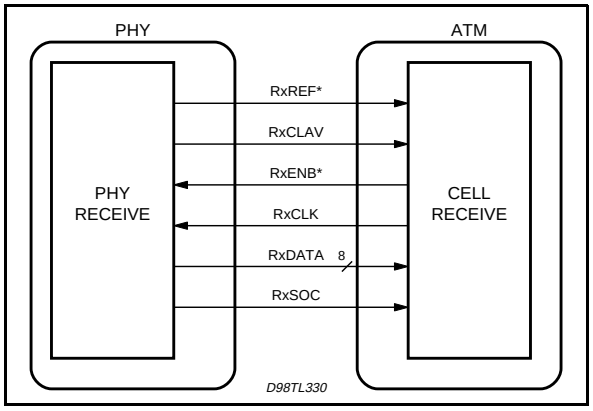

Figure 16. Transmit Interface

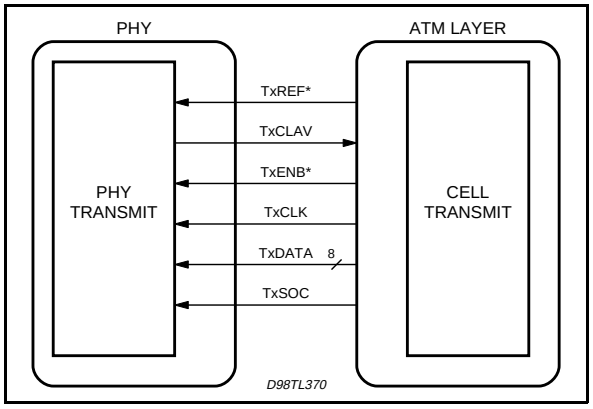
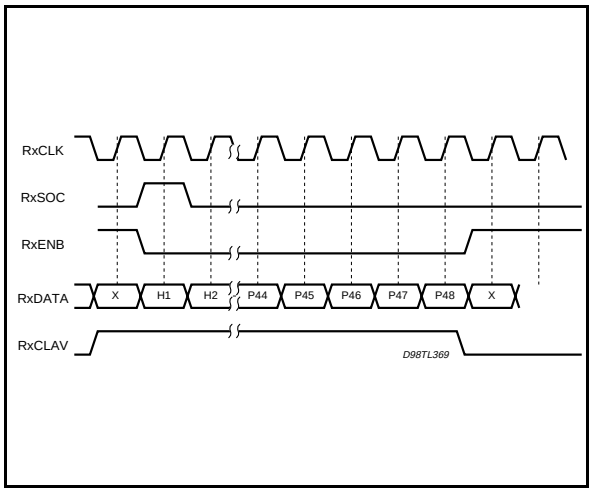


Utopia Level 1 Interface

The ATM forum takes the ATM layer chip as a reference. It defines the direction from ATM to physical layer as the Transmit direction. The direction from physical layer to ATM is the Receive direction. Figures 15 & 16 show the interconnection between ATM and PHY layer devices, the optional signals are not supported and not shown.

The Utopia interface transfers one byte in a single clock cycle, as a result cells are transformed in 53 clock cycles.
Both transmit and receive are synchronized on clocks generated by the ATM layer chip, and no specific relationship between receive and transmit clocks is required.
In this mode, the STLC60135 can only support one data flow : either interleaved or fast .

Figure 17. Timing (Utopia 1 Receive Interface)



Pin Description

Name	Type	Meaning	Usage	Remark
RxClav	O	Receive Cell available	Signals to the ATM chip that the STLC60135 has a cell ready for transfer	Remains active for the entire cell transfer
RxEnb*	I	Receive Enable	Signals to the STLC60135 that the ATM chip will sample and accept data during next clock cycle	RxData and RxSOC could be tri-state when RxEnb* is inactive (high). Active low signal
RxClk	I	Receive Byte Clock	Gives the timing signal for the transfer, generated by ATM layer chip.	
RxData	O	Receive Data (8bits)	ATM cell data, from STLC60135 chip to ATM chip, byte wide. Rx Data [7] is the MSB.	
RxSOC	O	Receive Start Cell	Identifies the cell boundary on RxData	Indicate to the ATM layer chip that RxData contains the first valid byte of a cell.
RxRef *	O	Reference Clock	8 kHz clock transported over the network	Active low signal

*Active low signal

When RxEnb is asserted, the STLC60135 reads data from its internal fifo and presents it on RxData and RxSOC on each low-to-high transition of RxClk, ie the ATM layer chip samples all RxData and RxSOC on the rising edge of RxSOC on the rising edge of RxClk.

Pin Description

Name	Type	Meaning	Usage	Remark
TxClav	O	Transmit Cell available	Signals to the ATM chip that the physical layer chip is ready to accept a complete cell	Remains active for the entire cell transfer
TxEnb*	I	Transmit Enable	Signals to the STLC60135 that TxData and TxSOC are valid	
TxClk	I	Transmit Byte Clock	Gives the timing signal for the transfer, generated by ATM layer chip.	
TxData	I	Transmit Data (8bits)	ATM cell data, from ATM layer chip to STLC60135, byte wide. TxData [7] is the MSB.	
TxSOC	I	Transmit Start of Cell	Identifies the cell boundary on TxData	TxData contains the first valid byte of the cell.
TxRef *	I	Reference Clock	8kHz clock from the ATM layer chip	

*Active low signal

The STLC60135 samples TxData and TxSOC signals on the rising edge of TxClk, if TxEnb is asserted.

TxClk, RxClk, AC electrical characteristics

Symbol	Parameters	Min	Max	Unit
F	Clock frequency	1.5	25	MHz
Tc	Clock duty cycle	40	60	%
Tj	Clock peak to peak jitter		5	%
Trf	Clock rise fall time		4	ns

T12	Signal going High impedance to RxClk	1		ns
L	Load		100	pF

Figure 18. Timing (Utopia 1 Transmit Interface)

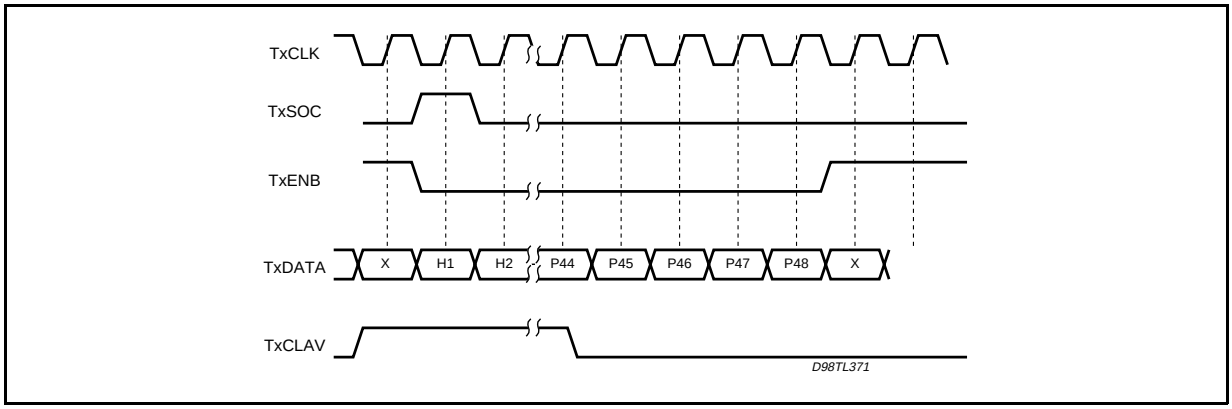

Figure 19. Timing Specification (Utopia 1)

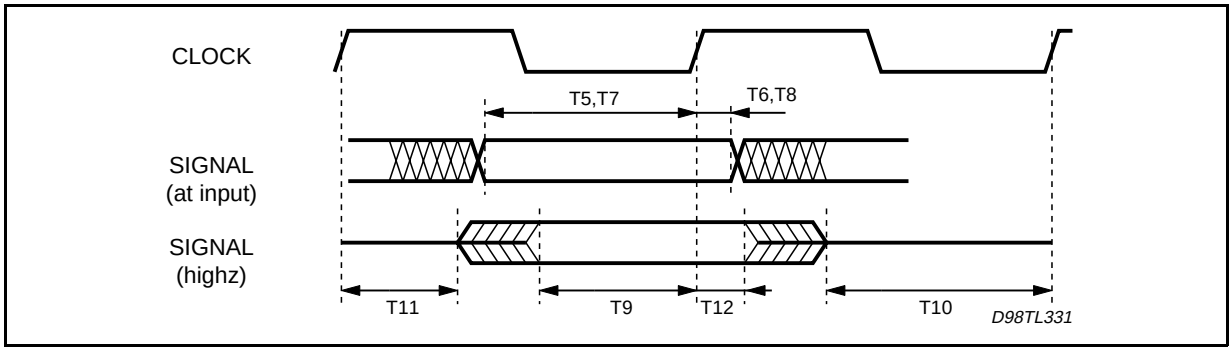


DIGITAL INTERFACE

Utopia Level 2 Interface

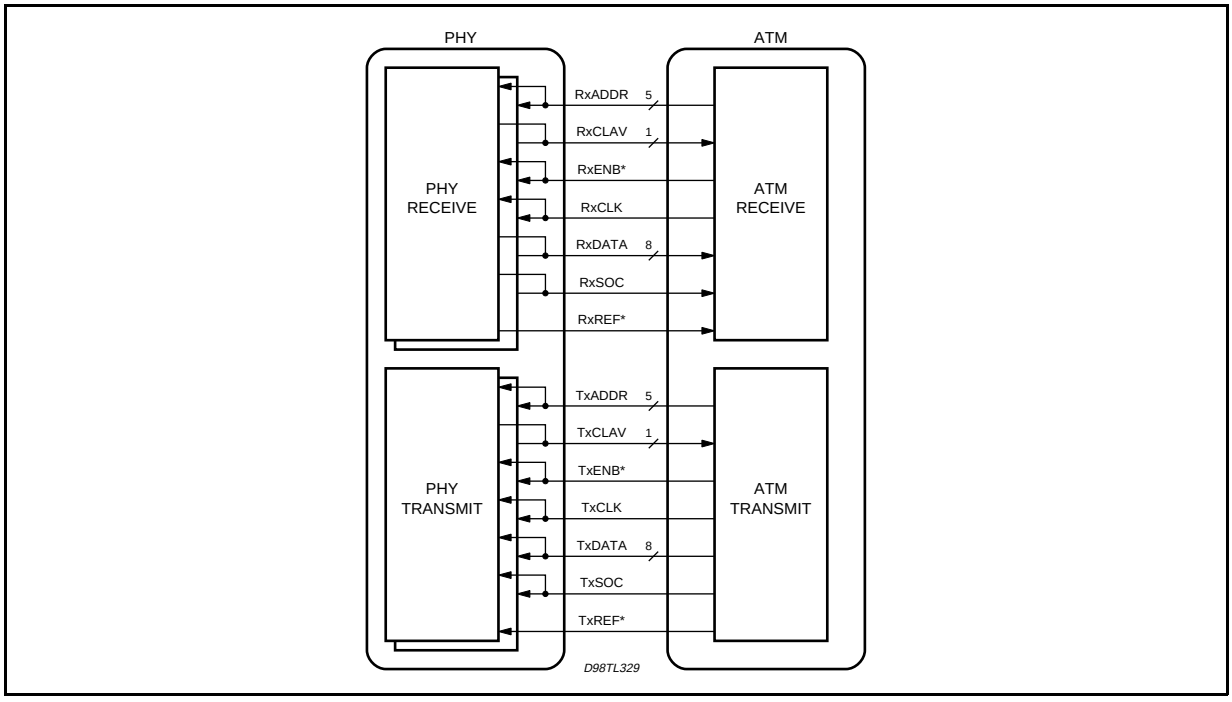
The ATM forum takes the ATM layer chip as a reference. It defines the direction from ATM to physical layer as the Transmit direction. The direction from physical layer to ATM is the Receive direction. Figure 20 shows the interconnection between ATM and PHY layer devices, the optional signals are not supported and not shown.

The UTOPIA interface transfers one byte in a single clock cycle, as a result cells are transferred in 53 clock cycles.
Both transmit and receive interfaces are synchronized on clocks generated by the ATM layer chip, and no specific relationship between Receive and Transmit clock is assumed, they must be regarded as mutually asynchronous clocks. Flow control signals are available to match the bandwidth constraints of the physical layer and the ATM layer. The UTOPIA level 2 supports point to multipoint configurations by introducing on addressing capability and by making a distinction between polling and selecting a device:

- the ATM chip polls a specific physical layer chip by putting its address on the address bus when the Enb* line is asserted. The addressed physical layer answers the next cycle via the Clav line reflecting its status at that time.

- the ATM chip selects a specific physical layer by putting its address on the address bus when the Enb* line is deasserted and asserting the Enb* line on the next cycle. The addressed physical layer chip will be the target or source of the next cell transfer.

Figure 20. Signal at Utopia Level 2 Interface



Utopia Level 2 Signals

The physical chip sends cell data towards the ATM layer chip.

The ATM layer chip polls the status of the fifo of the physical layer chip.

The cell exchange proceeds like:

a) The physical layer chip signals the availability of a cell by asserting RxClav when polled by the ATM chip.

b) The ATM chips selects a physical layer chip, then starts the transfer by asserting RxEnb*.

c) If the physical layer chip has data to send, it puts them on the RxData line the cycle after it sampled RxEnb* active. It also advances the offset in the cell. If the data transferred is the first byte of a cell, RxSOC is 1b at the time of the data transfer, 0b otherwise.

d) The ATM chip accepts the data when they are available. If RxSOC was 1b during the transfer, it resets its internal offset pointer to the value 1, otherwise it advances the offset in the cell.

STLC60135 Utopia Level 2 MPHY Operation

Utopia level 2 MPHY operation can be done by various interface schemes. The STLC60135 supports only the required mode, this mode is referred to as "Operation with 1 TxClav and 1 RxClav".

PHY Device Identification

The STLC60135 holds 2 PHY layer Utopia ports, one is dedicated to the fast data channel, the other one to the interleaved data channel. The associated PHY address is specified by the PHY_ADDR_x fields in the Utopia PHY address register. Beware that an incorrect address configuration may lead to bus conflicts. A feature is defined to disable (tri-state) all outputs of the Utopia interface. It is enabled by the TRI_STATE_EN bit in the Rx_interface control register.

Pin Description Utopia 2 (Receive Interface)

Name	Type	Meaning	Usage	Remark
RxClav	O	Receive Cell available	Signals to the ATM chip that the STLC60135 has a cell ready for transfer	Remains active for the entire cell transfer
RxEnb*	I	Receive Enable	Signals to the physical layer that the ATM chip will sample and accept data during next clock cycle	RxData and RxSOC could be tri-state when RxEnb* is inactive (high)
RxClk	I	Receive Byte Clock	Gives the timing signal for the transfer, generated by ATM layer chip.	
RxData	O	Receive Data (8 bits)	ATM cell data, from physical layer chip to ATM chip, byte wide.	
RxSOC	O	Receive Start Cell	Identifies the cell boundary on RxData	Indicate to the ATM layer chip that RxData contains the first valid byte of a cell.
RxAddr	I	Receive Address (5 bits)	Use to select the port that will be active or polled	
RxRef *	O	Reference Clock	8kHz clock transported over the network	

*Active low signal

Pin Description Utopia 2 (Transmit interface)

Name	Type	Meaning	Usage	Remark
TxClav	O	Transmit Cell available	Signals to the ATM chip that the physical layer chip is ready to accept a cell	Remains active for the entire cell transfer
TxEnb*	I	Transmit Enable	Signals to the physical layer that TxData and TxSOC are valid	
TxClk	I	Transmit Byte Clock	Gives the timing signal for the transfer, generated by ATM layer chip.	
TxData	I	Transmit Data (8 bits)	ATM cell data, to physical layer chip to ATM chip, byte wide.	
TxSOC	I	Transmit Start of Cell	Identifies the cell boundary on TxData	
TxAddr	I	Transmit Address (5 bits)	Use to select the port that will be active or polled	
TxRef *	I	Reference Clock	8kHz clock from the ATM layer chip	

*Active low signal

BitStream Interface

The Bitstream interface is a proprietary point to point interface. The STLC60135 is the bus master of the interface. The interface is synchronous, a common clock is used.

SLAP (Synchronous Link Access Protocol) Interface

The SLAP interface is a point to point bitstream interface. The STLC60135 is the bus master of the interface.

The interface is synchronous, a common clock (SLAP_CLOCK) is used. The basic idea is illustrated in Figure 20.

The SLAP interface dumps the data of the fast and interleaved channels on 2 separate sub interfaces.

The data flow from the SLAP interface must be enabled by the Transceiver Controller. A disabled cell interface does not dump data on its interface.

Receive SLAP Interface

The interface signals use 2 signal types: (refer to fig. 22)

- SLR_DATA [1:0]: data pins, a byte is transferred in 4 cycles of 2 bits. The msb are transmitted first, odd bits are asserted on SLR_DATA [1].

- SLR_VAL: indicates the data transfer and the byte boundary

- SLR_FRAME: indicates the start of a superframe

Notice 2 SLAP interfaces are supported, one for the fast data flow, the other one for the interleaved data flow.

The logic timing diagram is shown in figure 23.

Figure 21. Common Clock Data Transfer

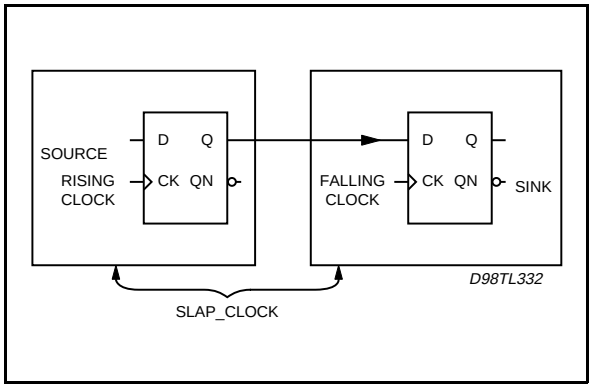


Figure 22. Receive Path, SLAP Interface

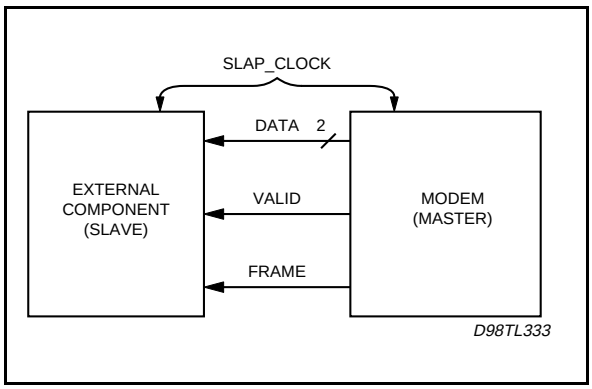

Figure 23. Receive SLAP Interface Timing

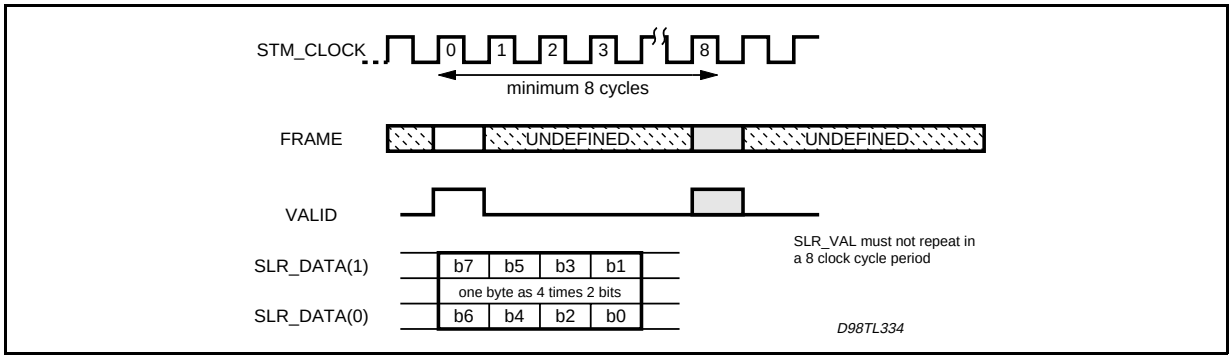

The implementation must guarantee that all active SLR_Valid signals must be separated by at least 8 clock cycles.

Refer to Figure 23. The SLR_FRAME signals are asserted when the first pair of bits of a frame are transferred. For the fast channel a frame is defined as a superframe timebase.

For the interleaved channel the frame is defined by a timebase period of 4 superframes. Both timebases are synchronized to the data flow.

Transmit SLAP Interface

The Transmit interface uses the following signals (refer to Figure 24)

- SLT_REQ: byte request
- SLT_FRAME: start of frame indication

Figure 24. Interface Towards PHY Layer

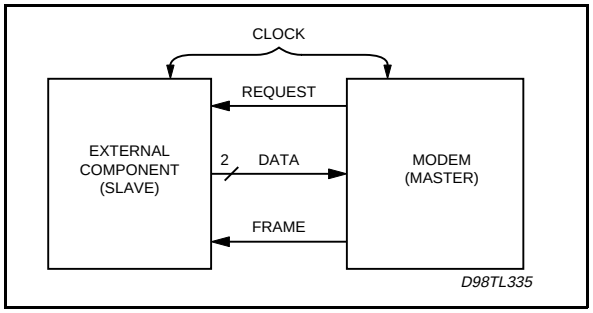

Figure 26. Interface Timing

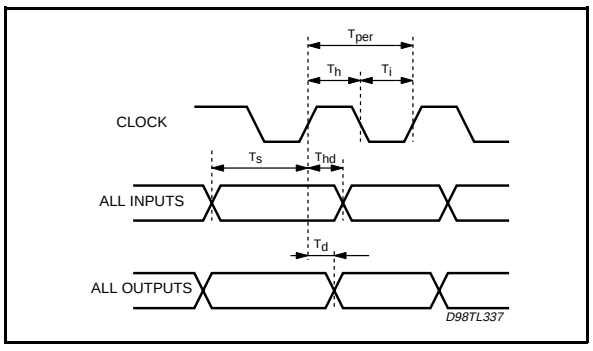


- SLT_DATA [1:0] data pins, a byte is transferred 2 bits at the time in 4 successive clock cycles. MSB first, odd bits on SLT_DATA [1]

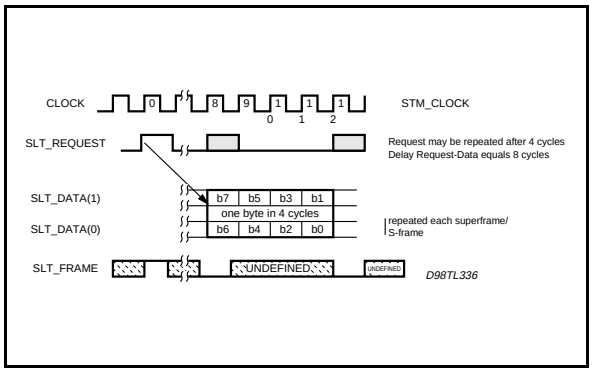
The logical timing diagram is shown in Figure 25. The delay between Request and the associated data byte is defined as 8 cycles.

The SLT_FRAME signals are asserted when the first pair of bits of a frame are transferred. For the fast channel a frame is defined as a superframe timebase.

For the interleaved channel the frame is defined by a timebase period of 4 superframes.

Both timebases are synchronized to the data flow and guarantee that the frame indication is asserted when the first bits of the first DMT symbol are transferred.

Figure 25. Transmit SLAP Interface Timing Diagram



SLAP INTERFACE, AC Electrical Characteristics

Td	Data Delay	20pF load	3		6	ns

■ Analog Front End Control Interface

The Analog Front End Interface is designed to be connected to the STLC60134 Analog Front End component.

Transmit Interface

The 16 bit words are multiplexed on 4 AFTXD output signals. As a result 4 cycles are needed to transfer 1 word. Refer to table 1 for the bit/pin allocation for the 4 cycles. The first of 4 cycles is identified by the CLWD signal. Refer to Figure 26.

Figure 27. Transmitt Word Timing Diagram

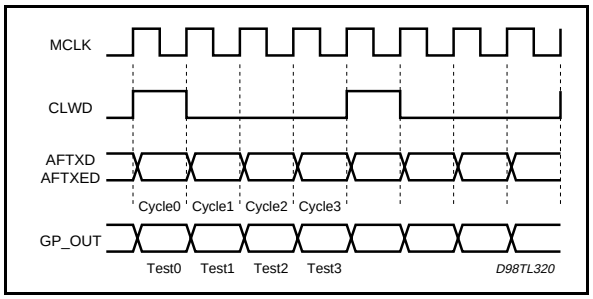

Figure 28. Receive Word Timing Diagram

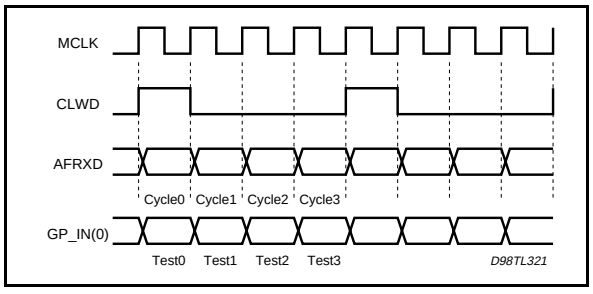

Figure 29. Transmit Interface

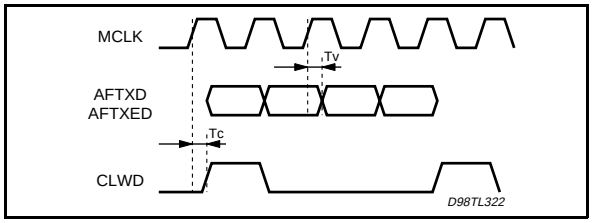

The STLC60135 fetches the 16 bit word to be multiplexed on AFTXD from the Tx Digital Front-End module.

Receive Interface

The 16 bit receive word is multiplexed on 4 AFRXD input signals. As a result 4 cycles are needed to transfer 1 word. Refer to Table 2 for the bit / pin allocation for the 4 cycles. The first of 4 cycles is identified by the CLWD must repeat after 4 MCLK cycles.

Tests, Clock, JTAG Interface

- Mclk: Master Clock (35.328MHz) generated by VCXO

- ATM receive interface, asynchronous clock generated by Utopia Master

- ATM transmit interface, asynchronous clock generated by Utopia Master

- ATC clock (Pclk): external asynchronous clock (synchronous with ATC in case of i960 specific interface)

JTAG TP interface: Standard Test Access Port, Used with the boundary scan for chip and board testing.
This JTAG TAP interface consists in 5 signals:

TDI, TDO, TCK & TMS.

TSRTB: Test Reset, reset the TAP controller. TRSTB is an active low signal.

bits from 3 to 15 are reserved

Reset Initialization

The STLC60135 supports two reset modes:

- A 'hardware' reset is activated by the RESETB pin (active low). A hard reset occurs when a low input value is detected at the RESETB input. The low level must be applied for at least 1ms to guarantee a correct reset operation. All clocks and power supplies must be stable for 200ns prior to the rising edge of the RESETB signal.
- 'Soft' reset activated by the controller write access to a soft reset configuration bit. The reset process takes less than 10000 MCLK clock cycles.

ELECTRICAL SPECIFICATIONS

Generic

The values presented in the following table apply for all inputs and/or outputs unless specified otherwise. Specifically they are not influenced by the choice between CMOS or TTL levels.

DC Electrical Characteristics

(All voltages are referenced to VSS, unless otherwise specified, positive current is towards the device)

IO Buffers Generic DC Characteristics

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
I_{IN}	Input Leakage Current	$V_{IN} = V_{SS}$, V_{DD} no pull up / pull down	-10		10	µA
I_{OZ}	Tristate Leakage Current	$V_{IN} = V_{SS}$, V_{DD} no pull up / pull down	-10		10	µA
I_{PU}	Pull up Current	$V_{IN} = V_{SS}$	-25	-66	-125	mA
I_{PD}	Pull Down Current	$V_{IN} = V_{DD}$	25	66	125	mA
R_{PU}	Pull up Resistance	$V_{IN} = V_{SS}$		50		KΩ
R_{PD}	Pull Down Resistance	$V_{IN} = V_{DD}$		50		KΩ

IO Buffers Dynamic DC Characteristics

Important for transient but measured at (near) DC

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
C_{IN}	Input Capacitance	@f = 1MHz		5		pF
dI/dt	Current Derivative	8mA driver, slew rate control		23.5		mA/ns
		8mA driver, no slew rate control		89	-125	mA/ns
I_{peak}	Peak Current	8mA driver, slew rate control		85		mA
		8mA driver, no slew rate control		100		mA
C_{OUT}	Output Capacitance (also bidirectional and tristate drivers)	@f = 1MHz		7		pF

Input / Output CMOS Generic Characteristics

The values presented in the following table apply for all CMOS inputs and/or outputs unless specified otherwise.

CMOS IO Buffers Generic Characteristics

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
V_{IL}	Low Level Input Voltage				0.2 x V_{DD}	V
V_{IH}	High Level Input Voltage		0.8 x V_{DD}			V
V_{HY}	Schmitt trigger hysteresis	slow edge < 1V/ms, only for SCHMITx	0.8			V
V_{OL}	Low Level Output Voltage	I_{OUT} = XmA*			0.4	V
V_{OH}	High Level Output Voltage	I_{OUT} = XmA*	0.85 x V_{DD}			V

* The reference current is dependent on the exact buffer chosen and is a part of the buffer name. The available values are 2, 4 and 8mA.

Input/ Output TTL Generic Characteristics

The values presented in the following table apply for all TTL inputs and/or outputs unless specified otherwise

Symbol	Parameter	Test Condition	Min.	Typ.	Max.	Unit
V_{IL}	Low Level Input Voltage				0.8	V
V_{IH}	High Level Input Voltage		2.0			V
V_{ILHY}	Low Level Threshold, falling	slow edge < 1V/ms	0.9		1.35	V
V_{IHHY}	High Level Threshold, rising	slow edge < 1V/ms	1.3		1.9	V
V_{HY}	Schmitt Trigger Hysteresis	slow edge < 1V/ms	0.4		0.7	V
V_{OL}	Low Level Output Voltage	I_{OUT} = XmA*			0.4	V
V_{OH}	High Level Output Voltage	I_{OUT} = XmA*	2.4			V

* The reference current is dependent on the exact buffer chosen and is a part of the buffer name. The available values are 2, 4 and 8mA.
