

## MUX-16/MUX-28

### FEATURES

- JFET Switches Rather Than CMOS
- Highly Resistant To Static Discharge Damage
- No SCR Latch-up Problems
- Low "ON" Resistance — 290Ω Typical
- Low Leakage Current
- Digital Inputs Compatible With TTL and CMOS
- Break-Before-Make Action
- 125° C Temperature-Tested Dice Available
- Overvoltage Protected
- Supply Loss Protection
- MUX-16 Pin Compatible With DG506, HI-506A, AD7506
- MUX-28 Pin Compatible With DG507, HI-507A, AD7507
- Available In Die Form

### ORDERING INFORMATION †

25°C RESISTANCE	PACKAGE			OPERATING TEMPERATURE RANGE

400Ω	—	—	MUX28FPC	XIND

\* For devices processed in total compliance to MIL-STD-883, add /883 after part number. Consult factory for 883 data sheet.

† Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.

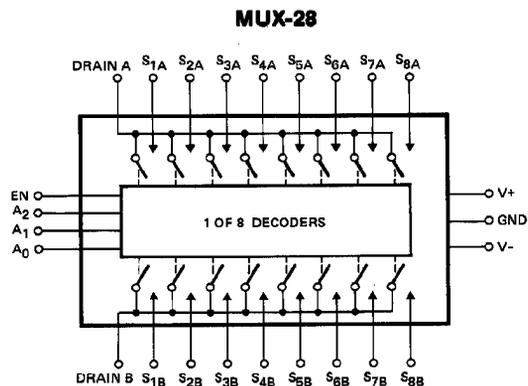

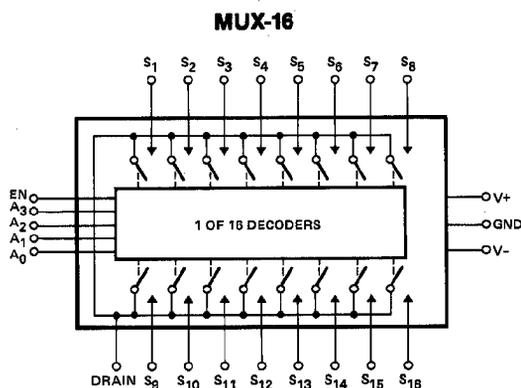

### GENERAL DESCRIPTION

The MUX-16 is a monolithic 16-channel analog multiplexer which connects a single output to 1 of the 16 analog inputs depending upon the state of a 4-bit binary address. Disconnection of the output is provided by a logical "0" at the ENABLE input, thereby providing a package selection function.

The MUX-28 is a monolithic 8-channel differential analog multiplexer configured in a double pole, 8-position (plus OFF) electronic switch array. A 3-bit binary input address connects a pair of independent analog inputs from each 8-channel input section to the corresponding pair of independent analog outputs. Disconnection of both inputs is provided by a logical "0" at the ENABLE input, thereby offering a package select function.

Fabricated with Precision Monolithics' high performance Bipolar-JFET technology, these devices offer low, constant "ON" resistance. Performance advantages include low leakage currents and fast settling time with low crosstalk to satisfy a wide variety of applications. These multiplexers do not suffer from latch-up or static discharge blow-out problems associated with similar CMOS parts. The digital inputs are designed to operate from both TTL and CMOS levels while always providing a definite break-before-make action without the need for external pull-up resistors. For single 8-channel and dual 4-channel models, refer to the MUX-08/MUX-24 data sheet.

### NOTES:

- Conditions applied to leakage tests insure worst case leakages.
- $R_L = 10M\Omega, C_L = 10pF$ .
- Crosstalk is measured by driving channel 8 (8B\*) with channel 7 (7B\*) ON.  
 $R_L = 1M\Omega, C_L = 10pF, V_S = 5V$  RMS,  $f = 500kHz$ .
- "OFF" isolation is measured by driving channel 8 (8B) with ALL channels OFF.  
 $R_L = 1k\Omega, C_L = 10pF, V_S = 5V$  RMS,  $f = 500kHz$ .  $C_{DS}$  is computed from the OFF isolation measurement.
- Sample tested.
- Guaranteed by leakage current and  $R_{ON}$  tests.

## APPLICATIONS INFORMATION

These analog multiplexers employ ion-implanted JFETs in a switch configuration designed to assure break-before-make (B.B.M.) action. The turn-off time is much faster than the turn-on time to guarantee B.B.M. over the full operating temperature and input voltage range. Fabricated with JFET processing rather than CMOS, special handling is not necessary to prevent damage to this multiplexer. Because the digital inputs only require a 2.0V logic "1" input level, power-consuming pullup resistors are not required for TTL compatibility to insure break-before-make switching as is most often the case with CMOS multiplexers. The digital inputs utilize PNP input transistors where input current is maximum at the logic "0" level and drops to that of a reverse-biased diode (about 10nA) as the input voltage is raised above  $\approx 1.4V$ .

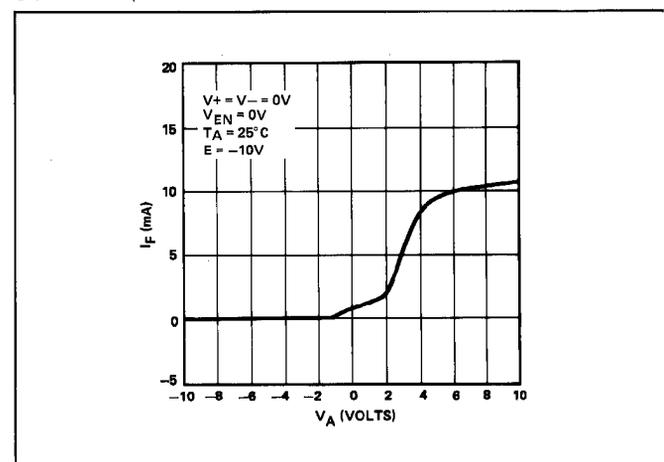

The "ON" resistance,  $R_{ON}$  of the analog switches is constant over the wide input voltage range of  $-15V$  to  $+11V$  with  $V_{SUPPLY} = \pm 15V$ . The overvoltage and supply-loss V-I characteristics shown indicate typical performance when the multiplexer is subjected to abnormal signals. For normal operation, however, positive input voltages should be restricted to 11V (or 4V less than the positive supply). This assures that the  $V_{GS}$  of an OFF FET switch remains greater than its  $V_P$ , preventing that channel from being falsely turned ON.

When operating with negative input voltages, the gate-to-channel diode will be turned on if the voltage drop across an ON switch exceeds  $-0.6V$ . While this condition will cause an error in the output, it will not damage the switch. In lab tests, the multiplexer output has been loaded with a  $0.01\mu F$  capacitor in the circuit of Figure 1. With  $V_1 = -10V$  and  $V_{16} = +10V$ , the logic input was driven at a 1kHz rate. The positive-going slew rate was  $0.3V/\mu Sec$  which is equivalent to a normal  $I_{DSS}$  of 3mA. The negative-going slew rate was  $0.7V/\mu sec$  which is equivalent to a "reverse"  $I_{DSS}$  of 7mA. Note that when switch one (1) is first turned ON it has a drop of  $-20V$  across its terminals. In spite of that fact, the current is limited to approximately twice its normal  $I_{DSS}$ .
