Preface

The *S3C8238/C8235/F8235 Microcontroller User's Manual* is designed for application designers and programmers who are using the S3C8238/C8235/F8235 microcontroller for application development.
It is organized in two main parts:

Part I	Programming Model	Part II	Hardware Descriptions

Part I contains software-related information to familiarize you with the microcontroller's architecture, programming model, instruction set, and interrupt structure. It has six chapters:

Chapter 1	Product Overview	Chapter 4	Control Registers
Chapter 2	Address Spaces	Chapter 5	Interrupt Structure
Chapter 3	Addressing Modes	Chapter 6	Instruction Set

Chapter 1, "Product Overview," is a high-level introduction to S3C8238/C8235/F8235 with general product descriptions, as well as detailed information about individual pin characteristics and pin circuit types.

Chapter 2, "Address Spaces," describes program and data memory spaces, the internal register file, and register addressing. Chapter 2 also describes working register addressing, as well as system stack and user-defined stack operations.

Chapter 3, "Addressing Modes," contains detailed descriptions of the addressing modes that are supported by the S3C8-series CPU.

Chapter 4, "Control Registers," contains overview tables for all mapped system and peripheral control register values, as well as detailed one-page descriptions in a standardized format. You can use these easy-to-read, alphabetically organized, register descriptions as a quick-reference source when writing programs.

Chapter 5, "Interrupt Structure," describes the S3C8238/C8235/F8235 interrupt structure in detail and further prepares you for additional information presented in the individual hardware module descriptions in Part II.

Chapter 6, "Instruction Set," describes the features and conventions of the instruction set used for all S3C8-series microcontrollers. Several summary tables are presented for orientation and reference. Detailed descriptions of each instruction are presented in a standard format. Each instruction description includes one or more practical examples of how to use the instruction when writing an application program.

A basic familiarity with the information in Part I will help you to understand the hardware module descriptions in Part II. If you are not yet familiar with the S3C-series microcontroller family and are reading this manual for the first time, we recommend that you first read Chapters 1–3 carefully. Then, briefly look over the detailed information in Chapters 4, 5, and 6. Later, you can reference the information in Part I as necessary.

Part II "hardware Descriptions," has detailed information about specific hardware components of the S3C8238/C8235/F8235 microcontroller. Also included in Part II are electrical, mechanical, Flash MCU, and development tools data. It has 16 chapters:

Chapter 7	Clock Circuit	Chapter 15	10-bit Analog-to-Digital Converter
Chapter 8	RESET and Power-Down	Chapter 16	Voltage Booster
Chapter 9	I/O Ports	Chapter 17	Voltage Level Detector
Chapter 10	Basic Timer	Chapter 18	Pattern Generation Module
Chapter 11	8-bit Timer A/B	Chapter 19	Electrical Data
Chapter 12	16-bit Timer 1	Chapter 20	Mechanical Data
Chapter 13	Watch Timer	Chapter 21	S3F8235 Flash MCU
Chapter 14	LCD Controller/Driver	Chapter 22	Development Tools

Two order forms are included at the back of this manual to facilitate customer order for S3C8238/C8235/F8235 microcontrollers: the Mask ROM Order Form, and the Mask Option Selection Form. You can photocopy these forms, fill them out, and then forward them to your local Samsung Sales Representative.

1 PRODUCT OVERVIEW

S3C8-SERIES MICROCONTROLLERS

Samsung's S3C8-series of 8-bit single-chip CMOS microcontrollers offers a fast and efficient CPU, a wide range of integrated peripherals, and various mask-programmable ROM sizes. The major CPU features are:

— Efficient register-oriented architecture
— Selectable CPU clock sources
— Idle and Stop power-down mode released by interrupt or reset
— Built-in basic timer with watchdog function

A sophisticated interrupt structure recognizes up to eight interrupt levels. Each level can have one or more interrupt sources and vectors. Fast interrupt processing (within a minimum of four CPU clocks) can be assigned to specific interrupt levels.

S3C8238/C8235/F8235 MICROCONTROLLER

The S3C8238/C8235/F8235 single-chip CMOS microcontrollers are fabricated using the highly advanced CMOS process, based on Samsung's latest CPU architecture.

The S3C8235 is a microcontroller with a 16K-byte mask-programmable ROM embedded.

The S3F8235 is a microcontroller with a 16K-byte Flash ROM embedded.

Using a proven modular design approach, Samsung engineers have successfully developed the S3C8238/C8235/F8235 by integrating the following peripheral modules with the powerful SAM8 core:

— Five programmable I/O ports, including three 8-bit ports and two 4-bit ports, for a total of 32 pins.
— Eight bit-programmable pins for external interrupts.
— One 8-bit basic timer for oscillation stabilization and watchdog function (system reset).
— Two 8-bit timer/counter and one 16-bit timer/counter with selectable operating modes.
— Watch timer for real time
— 8-channel A/D converter

The S3C8238/C8235/F8235 is versatile microcontroller for camera, LCD and ADC application, etc. They are currently available in 64-pin LQFP, 64-pin QFP and 64-pin SDIP package.

FEATURES

CPU

- SAM88RC CPU core

Memory

- 16K-bytes ROM
- 632 -bytes RAM

Oscillation Sources

- Crystal, Ceramic, RC
- Crystal for subsystem clock
- CPU clock divider (1/1, 1/2, 1/8, 1/16)

Instruction Set

- 78 instructions
- IDLE and STOP instructions added for power-down modes

Instruction Execution Time

- 400 ns at 10-MHz f_{OSC} (minimum)

Interrupts

- 16 interrupt sources with 16 vector.
- 8 level, 16 vector interrupt structure

I/O Ports

- Total 32 bit-programmable pins

Timers and Timer/Counters

- One programmable 8-bit basic timer (BT) for oscillation stabilization control or watchdog timer function
- One 8-bit timer/counter (**Timer A**) with three operating modes; Interval mode, capture mode and PWM mode.
- One 8-bit timer/counter (**Timer B**) Carrier frequency (or PWM) generator.
- One 16-bit capture timer/counter (**Timer 1**) with two operating modes; Interval mode, Capture mode for pulse period or duty.

Watch Timer

- Real-time and interval time measurement.
- Clock generation for LCD.

LCD Controller/Driver

- 8(4)COM X 24SEG (MAX 24 digit)

A/D Converter

- Eight analog input channels
- 20us conversion speed at 10MHz f_{ADC} clock.

Voltage Booster

- LCD drive voltage supply
- S/W control (Enable/Disable)

Low Voltage Reset(LVR)

- Low Voltage Check to make system reset
- V_{LVR} = 2.2V/2.6V/3.6V

Pattern Generation Module

- Pattern generation module triggered by timer match signal and S/W.

Voltage Detector for Indication

- Voltage Detector to indicate specific voltage.
- S/W control (2.4V, 2.7V, 3.3V, 4.5V)

Key Strobe Mode

- Support automatic key strobe output with LCD driver(Maximum 4 x 12 key matrices).

Operating Temperature Range

- -40°C to + 85°C

Operating Voltage Range

- 2.0 V to 5.5 V at 4 MHz f_{OSC} (Preliminary)

Package Type

- 64 pin SDIP, 64 pin QFP, 64 pin LQFP

Smart Option

- Low Voltage Reset(LVR) level and enable/disable are at your hardwired option. (ROM address 3E,3FH)

2 ADDRESS SPACES

OVERVIEW

The S3C8238/C8235/F8235 microcontroller has two types of address space:

— Internal program memory (ROM)
— Internal data memory (RAM)

A 16-bit address bus supports program memory operations. A separate 8-bit register bus carries addresses and data between the CPU and the register file.

The S3C8238/C8235/F8235 has an internal 8/16-Kbyte mask-programmable ROM and 632-byte RAM.

PROGRAM MEMORY (ROM)

Program memory (ROM) stores program codes or table data. The S3C8238 has 8 Kbytes of internal mask-programmable program memory. The S3C8235/F8235 has 16 Kbytes of internal mask programmable program memory. The program memory address range is therefore 0H–3FFFH (see Figure 2-1).

The first 256 bytes of the ROM (0H-0FFH) are reserved for interrupt vector addresses. Unused locations in this address range can be used as normal program memory. If you use the vector address area to store a program code, be careful not to overwrite the vector addresses stored in these locations.

The ROM address at which a program execution starts after a reset is 0100H.

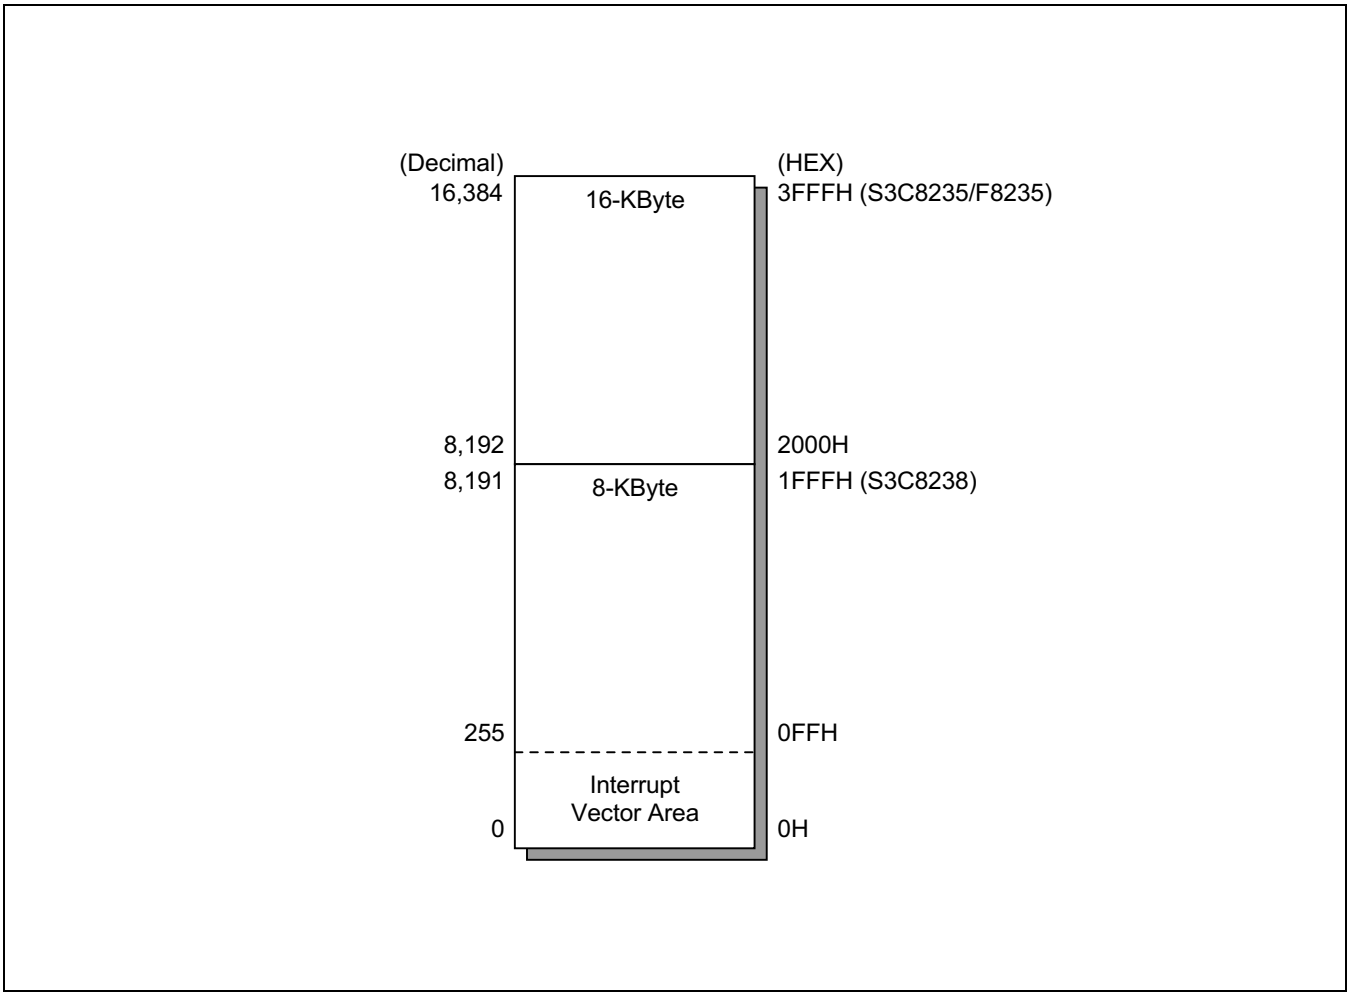

Figure 2-1. Program Memory Address Space

SMART OPTION

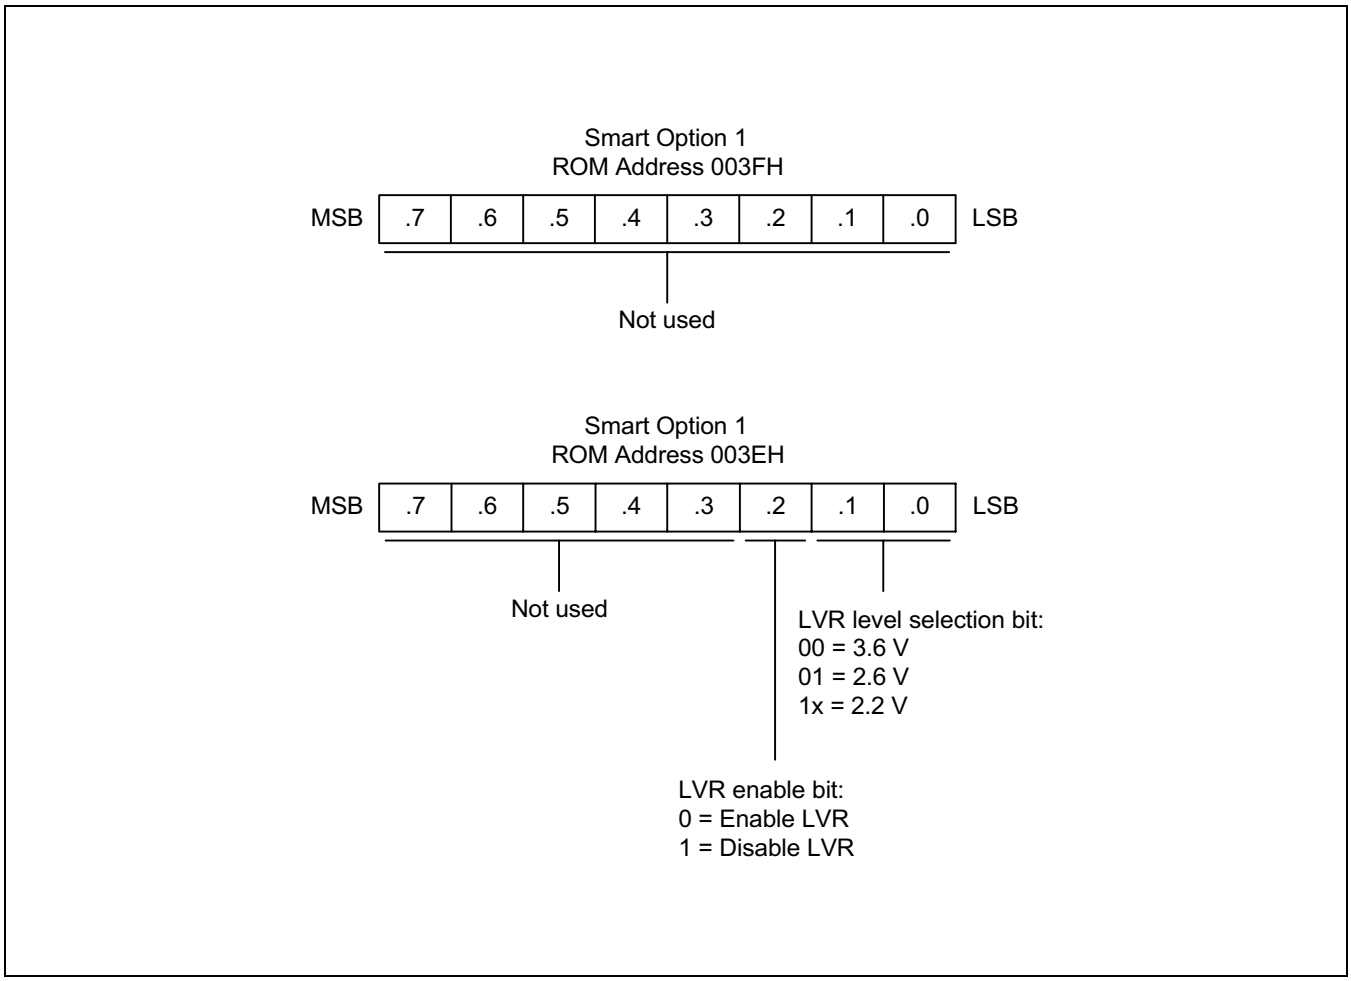

Figure 2-2. Smart Option

Smart option is the ROM option for start condition of the chip. The ROM address used by smart option is from 003EH to 003FH. The S3C8235/C8238/F8235 only use 003EH. The default value of ROM is FFH (LVR disable)

REGISTER ARCHITECTURE

In the S3C8238/C8235/F8235 implementation, the upper 64-byte area of register files is expanded two 64-byte areas, called *set 1* and *set 2*. The upper 32-byte area of set 1 is further expanded two 32-byte register banks (bank 0 and bank 1), and the lower 32-byte area is a single 32-byte common area. In addition, set 2 is logically expanded 2 separately addressable register pages, page 0–page 1.

In case of S3C8238/C8235/F8235 the total number of addressable 8-bit registers is 632. Of these 632 registers, 16 bytes are for CPU and system control registers, 24 bytes are for LCD data registers, 64 bytes are for peripheral control and data registers, 16 bytes are used as a shared working registers, and 512 registers are for general-purpose use.

You can always address set 1 register locations, regardless of which of the 2 register pages is currently selected. Set 1 locations, however, can only be addressed using direct addressing modes.

The extension of register space into separately addressable areas (sets, banks, and pages) is supported by various addressing mode restrictions, the select bank instructions, SB0 and SB1, and the register page pointer (PP).

Specific register types and the area (in bytes) that they occupy in the register file are summarized in Table 2–1.

Table 2-1. S3C8238/C8235/F8235 Register Type Summary

Register Type	Number of Bytes
General-purpose registers (including the 16-byte common working register area, two 192-byte prime register area, and two 64-byte set 2 area)	528
LCD data registers	24
CPU and system control registers	16
Mapped clock, peripheral, I/O control, and data registers	64
Total Addressable Bytes	632

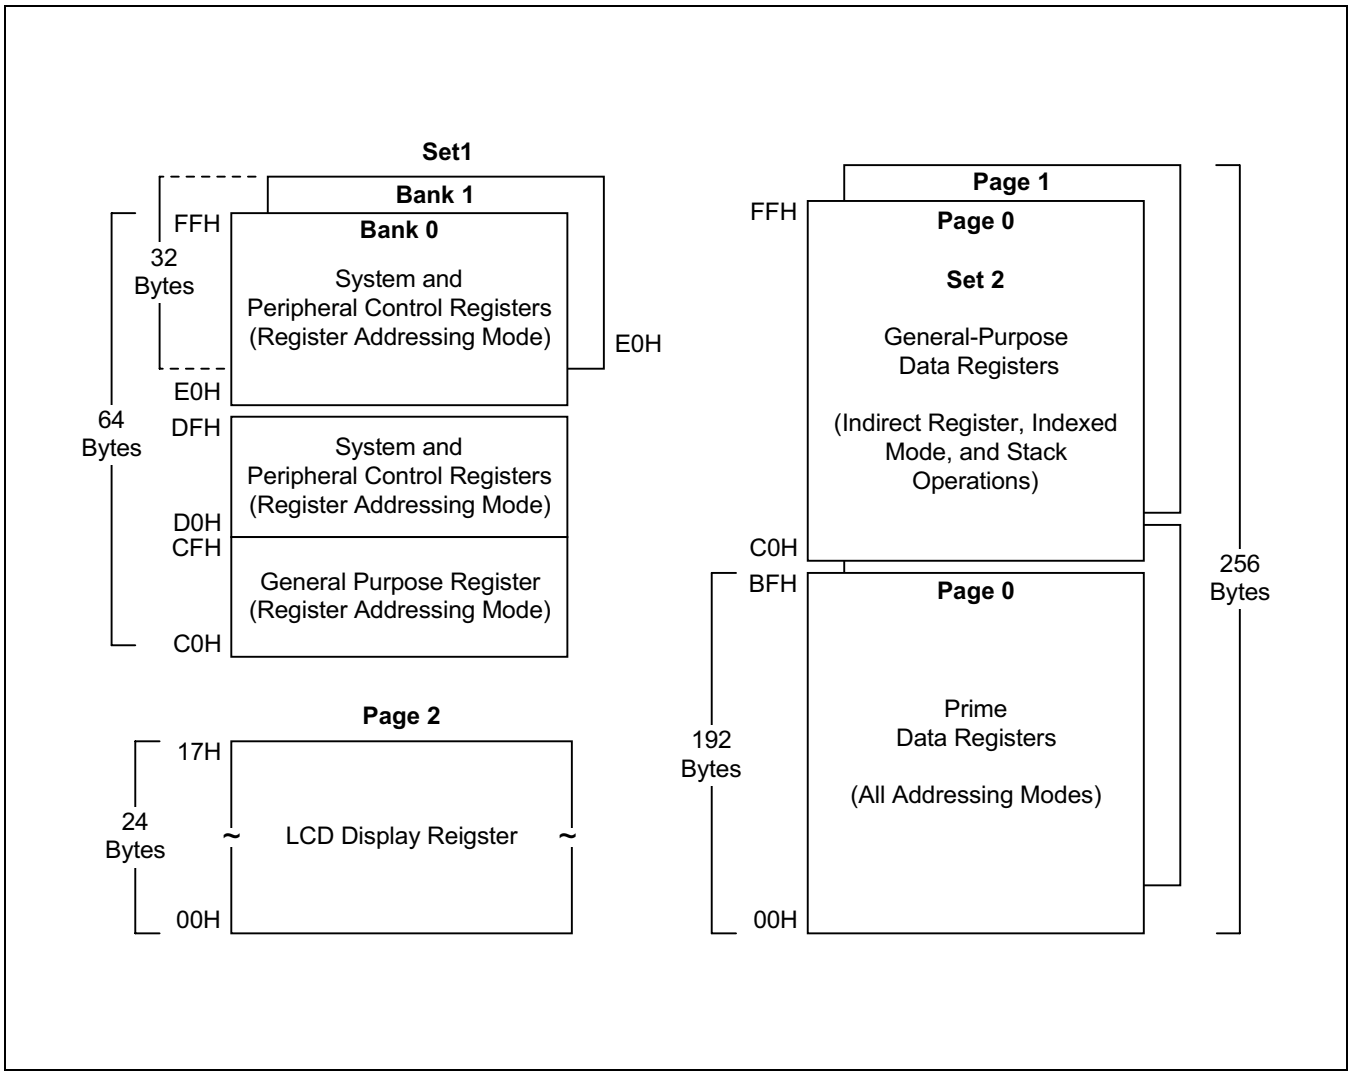

Figure 2-3. Internal Register File Organization

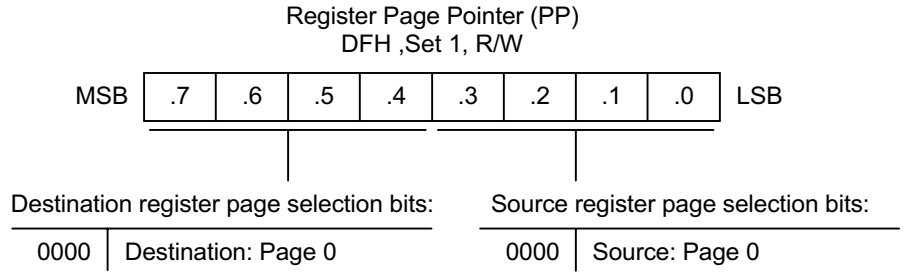
REGISTER PAGE POINTER (PP)

The S3C8-series architecture supports the logical expansion of the physical 256-byte internal register file (using an 8-bit data bus) into as many as 16 separately addressable register pages. Page addressing is controlled by the register page pointer (PP, DFH). In the S3C8238/C8235/F8235 microcontroller, a paged register file expansion is implemented for LCD data registers, and the register page pointer must be changed to address other pages.

After a reset, the page pointer's source value (lower nibble) and the destination value (upper nibble) are always "0000", automatically selecting page 0 as the source and destination page for register addressing.



NOTE: In the S3C8238/C8235/F8235 microcontroller, pages 0, 1, and 2 are implemented. A hardware reset operation writes the 4-bit destination and source values shown above to the register page pointer. These values should be modified to address other pages.

Figure 2-4. Register Page Pointer (PP)

☞ PROGRAMMING TIP — Using the Page Pointer for RAM clear (Page 0, Page 1)

```
        LD      PP,#00H         ;  Destination ← 0, Source ← 0
        SRP     #0C0H
        LD      R0,#0FFH        ;  Page 0 RAM clear starts
RAMCL0  CLR     @R0
        DJNZ    R0,RAMCL0
        CLR     @R0             ;  R0 = 00H

        LD      PP,#10H         ;  Destination ← 1, Source ← 0
        LD      R0,#0FFH        ;  Page 1 RAM clear starts
RAMCL1  CLR     @R0
        DJNZ    R0,RAMCL1
        CLR     @R0             ;  R0 = 00H
```

NOTE: You should refer to page 6-39 and use DJNZ instruction properly when DJNZ instruction is used in your program.

REGISTER SET 1

The term *set 1* refers to the upper 64 bytes of the register file, locations C0H–FFH.

The upper 32-byte area of this 64-byte space (E0H–FFH) is expanded two 32-byte register banks, *bank 0* and *bank 1*. The set register bank instructions, SB0 or SB1, are used to address one bank or the other. A hardware reset operation always selects bank 0 addressing.

The upper two 32-byte areas (bank 0 and bank 1) of set 1 (E0H–FFH) contains 48 mapped system and peripheral control registers. The lower 32-byte area contains 16 system registers (D0H–DFH) and a 16-byte common working register area (C0H–CFH).

Registers in set 1 locations are directly accessible at all times using Register addressing mode. The 16-byte working register area can only be accessed using working register addressing (For more information about working register addressing, please refer to Chapter 3, “Addressing Modes.”)

REGISTER SET 2

The same 64-byte physical space that is used for set 1 locations C0H–FFH is logically duplicated to add another 64 bytes of register space. This expanded area of the register file is called set *2*. For the S3C8328/C8325/F8235, the set 2 address range (C0H–FFH) is accessible on pages 0-1.

The logical division of set 1 and set 2 is maintained by means of addressing mode restrictions. You can use only Register addressing mode to access set 1 locations. In order to access registers in set 2, you must use Register Indirect addressing mode or Indexed addressing mode.

The set 2 register area is commonly used for stack operations.

PRIME REGISTER SPACE

The lower 192 bytes (00H–BFH) of the S3C8238/C8235/F8235's two 256-byte register pages is called *prime register area.* Prime registers can be accessed using any of the seven addressing modes (see Chapter 3, "Addressing Modes.")

The prime register area on page 0 is immediately addressable following a reset. In order to address prime registers on pages 0, or 1 you must set the register page pointer (PP) to the appropriate source and destination values.

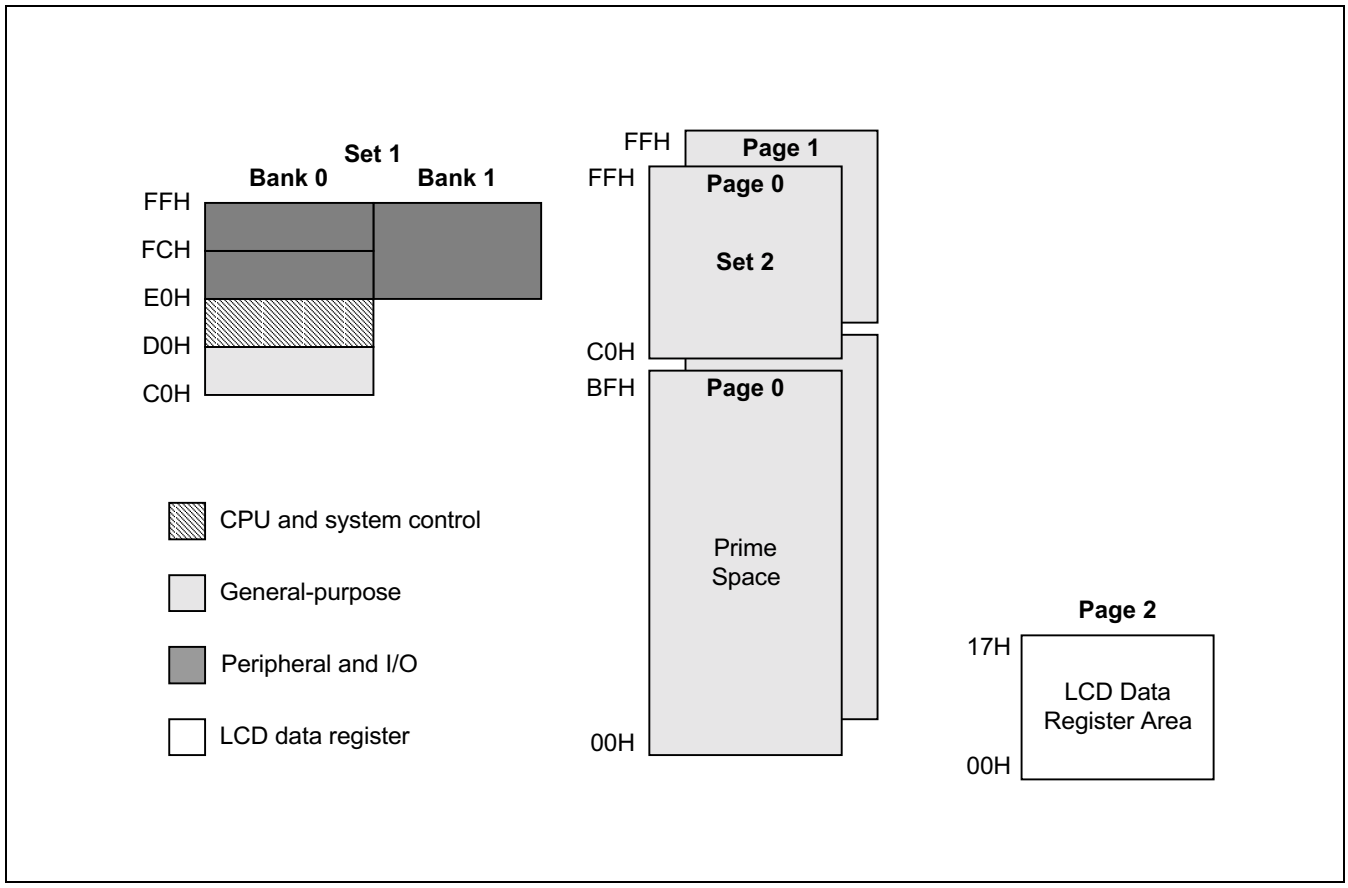


Figure 2-5. Set 1, Set 2, Prime Area Register, and LCD Data Register Map

WORKING REGISTERS

Instructions can access specific 8-bit registers or 16-bit register pairs using either 4-bit or 8-bit address fields. When 4-bit working register addressing is used, the 256-byte register file can be seen by the programmer as one that consists of 328-byte register groups or "slices." Each slice comprises of eight 8-bit registers.

Using the two 8-bit register pointers, RP1 and RP0, two working register slices can be selected at any one time to form a 16-byte working register block. Using the register pointers, you can move this 16-byte register block anywhere in the addressable register file, except for the set 2 area.

The terms slice and block are used in this manual to help you visualize the size and relative locations of selected working register spaces:

— One working register *slice* is 8 bytes (eight 8-bit working registers, R0–R7 or R8–R15)

— One working register *block* is 16 bytes (sixteen 8-bit working registers, R0–R15)

All the registers in an 8-byte working register slice have the same binary value for their five most significant address bits. This makes it possible for each register pointer to point to one of the 24 slices in the register file. The base addresses for the two selected 8-byte register slices are contained in register pointers RP0 and RP1.

After a reset, RP0 and RP1 always point to the 16-byte common area in set 1 (C0H–CFH).

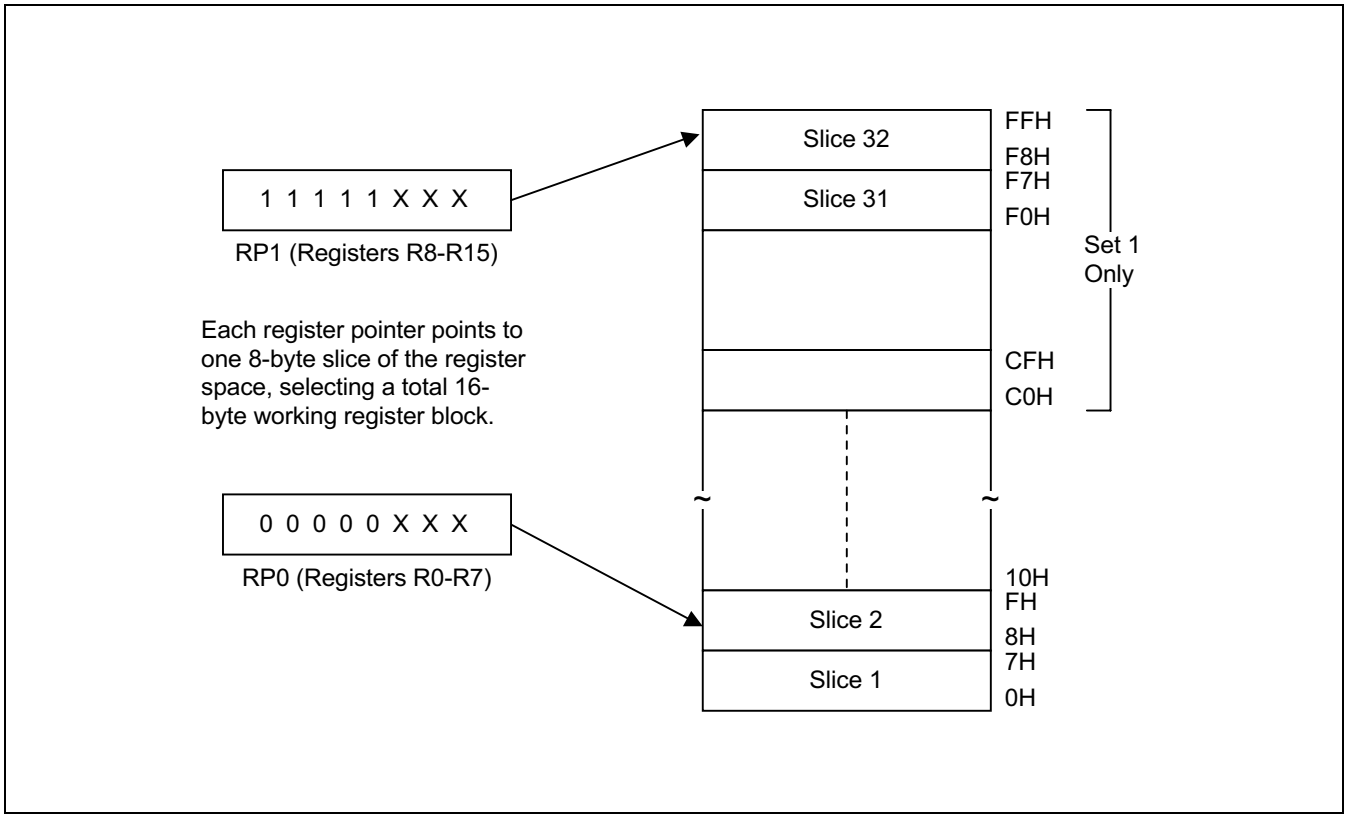

Figure 2-6. 8-Byte Working Register Areas (Slices)

USING THE REGISTER POINTS

After a reset, RP# point to the working register common area: RP0 points to addresses C0H–C7H, and RP1 points to addresses C8H–CFH.

To change a register pointer value, you load a new value to RP0 and/or RP1 using an SRP or LD instruction. (see Figures 2-6 and 2-7).

With working register addressing, you can only access those two 8-bit slices of the register file that are currently pointed to by RP0 and RP1. You cannot, however, use the register pointers to select a working register space in set 2, C0H–FFH, because these locations can be accessed only using the Indirect Register or Indexed addressing modes.

The selected 16-byte working register block usually consists of two contiguous 8-byte slices. As a general programming guideline, it is recommended that RP0 point to the "lower" slice and RP1 point to the "upper" slice (see Figure 2-6).

Because a register pointer can point to either of the two 8-byte slices in the working register block, you can flexibly define the working register area to support program requirements.

☞ PROGRAMMING TIP — Setting the Register Pointers

```
SRP     #70H          ;  RP0 ← 70H, RP1 ← 78H
SRP1    #48H          ;  RP0 ← no change, RP1 ← 48H,
SRP0    #0A0H         ;  RP0 ← A0H, RP1 ← no change
CLR     RP0           ;  RP0 ← 00H, RP1 ← no change
LD      RP1,#0F8H     ;  RP0 ← no change, RP1 ← 0F8H
```

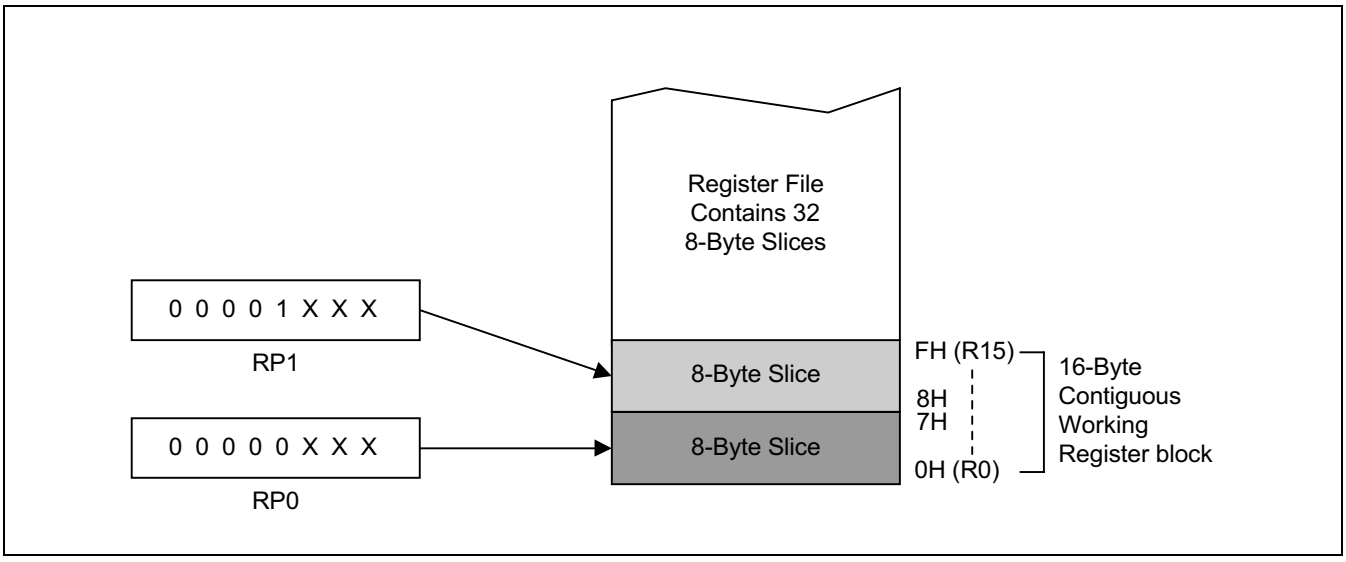

Figure 2-7. Contiguous 16-Byte Working Register Block

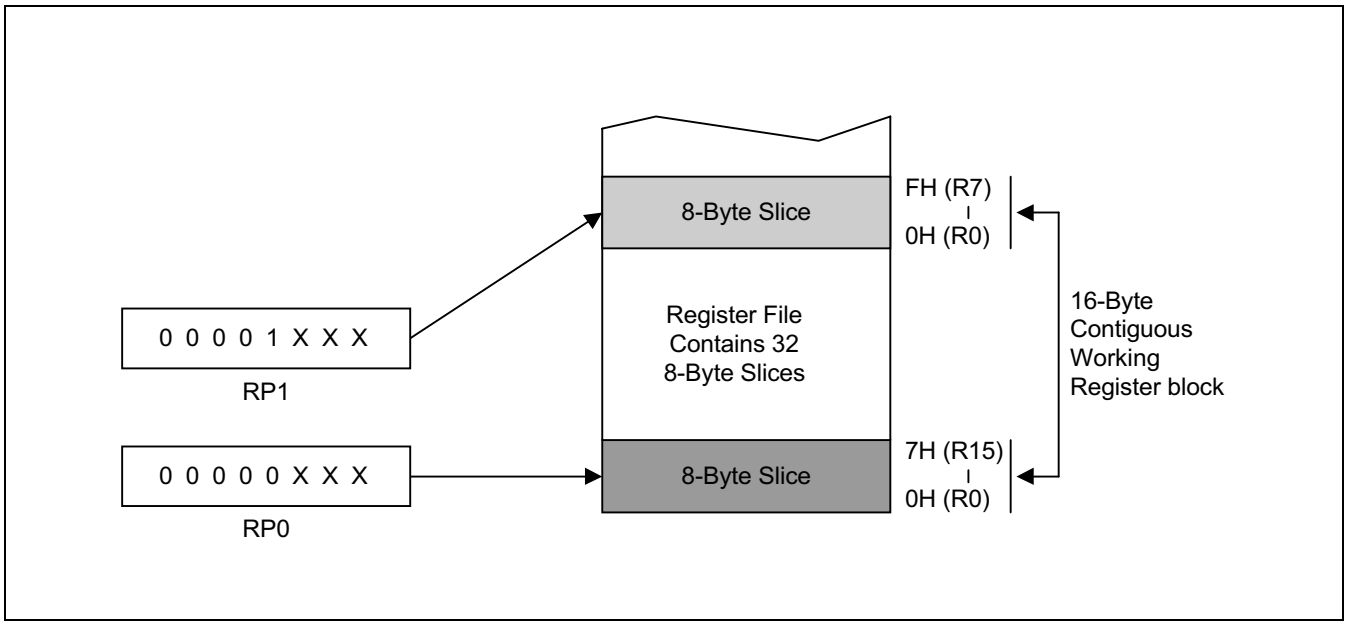

Figure 2-8. Non-Contiguous 16-Byte Working Register Block

☞ PROGRAMMING TIP — Using the RPs to Calculate the Sum of a Series of Registers

Calculate the sum of registers 80H–85H using the register pointer. The register addresses from 80H through 85H contain the values 10H, 11H, 12H, 13H, 14H, and 15 H, respectively:

```
SRP0    #80H        ;  RP0 ← 80H
ADD     R0,R1       ;  R0 ← R0 + R1
ADC     R0,R2       ;  R0 ← R0 + R2 + C
ADC     R0,R3       ;  R0 ← R0 + R3 + C
ADC     R0,R4       ;  R0 ← R0 + R4 + C
ADC     R0,R5       ;  R0 ← R0 + R5 + C
```

The sum of these six registers, 6FH, is located in the register R0 (80H). The instruction string used in this example takes 12 bytes of instruction code and its execution time is 36 cycles. If the register pointer is not used to calculate the sum of these registers, the following instruction sequence would have to be used:

```
ADD     80H,81H     ;  80H ← (80H) + (81H)
ADC     80H,82H     ;  80H ← (80H) + (82H) + C
ADC     80H,83H     ;  80H ← (80H) + (83H) + C
ADC     80H,84H     ;  80H ← (80H) + (84H) + C
ADC     80H,85H     ;  80H ← (80H) + (85H) + C
```

Now, the sum of the six registers is also located in register 80H. However, this instruction string takes 15 bytes of instruction code rather than 12 bytes, and its execution time is 50 cycles rather than 36 cycles.

REGISTER ADDRESSING

The S3C-series register architecture provides an efficient method of working register addressing that takes full advantage of shorter instruction formats to reduce execution time.

With Register (R) addressing mode, in which the operand value is the content of a specific register or register pair, you can access any location in the register file except for set 2. With working register addressing, you use a register pointer to specify an 8-byte working register space in the register file and an 8-bit register within that space.

Registers are addressed either as a single 8-bit register or as a paired 16-bit register space. In a 16-bit register pair, the address of the first 8-bit register is always an even number and the address of the next register is always an odd number. The most significant byte of the 16-bit data is always stored in the even-numbered register, and the least significant byte is always stored in the next (+1) odd-numbered register.

Working register addressing differs from Register addressing as it uses a register pointer to identify a specific 8-byte working register space in the internal register file and a specific 8-bit register within that space.

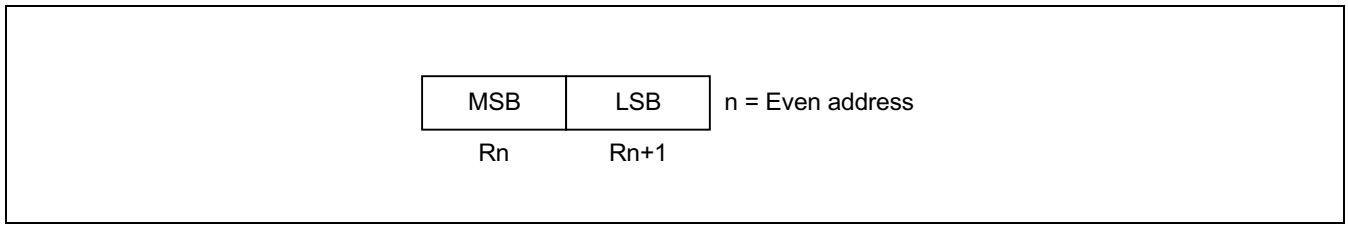

Figure 2-9. 16-Bit Register Pair

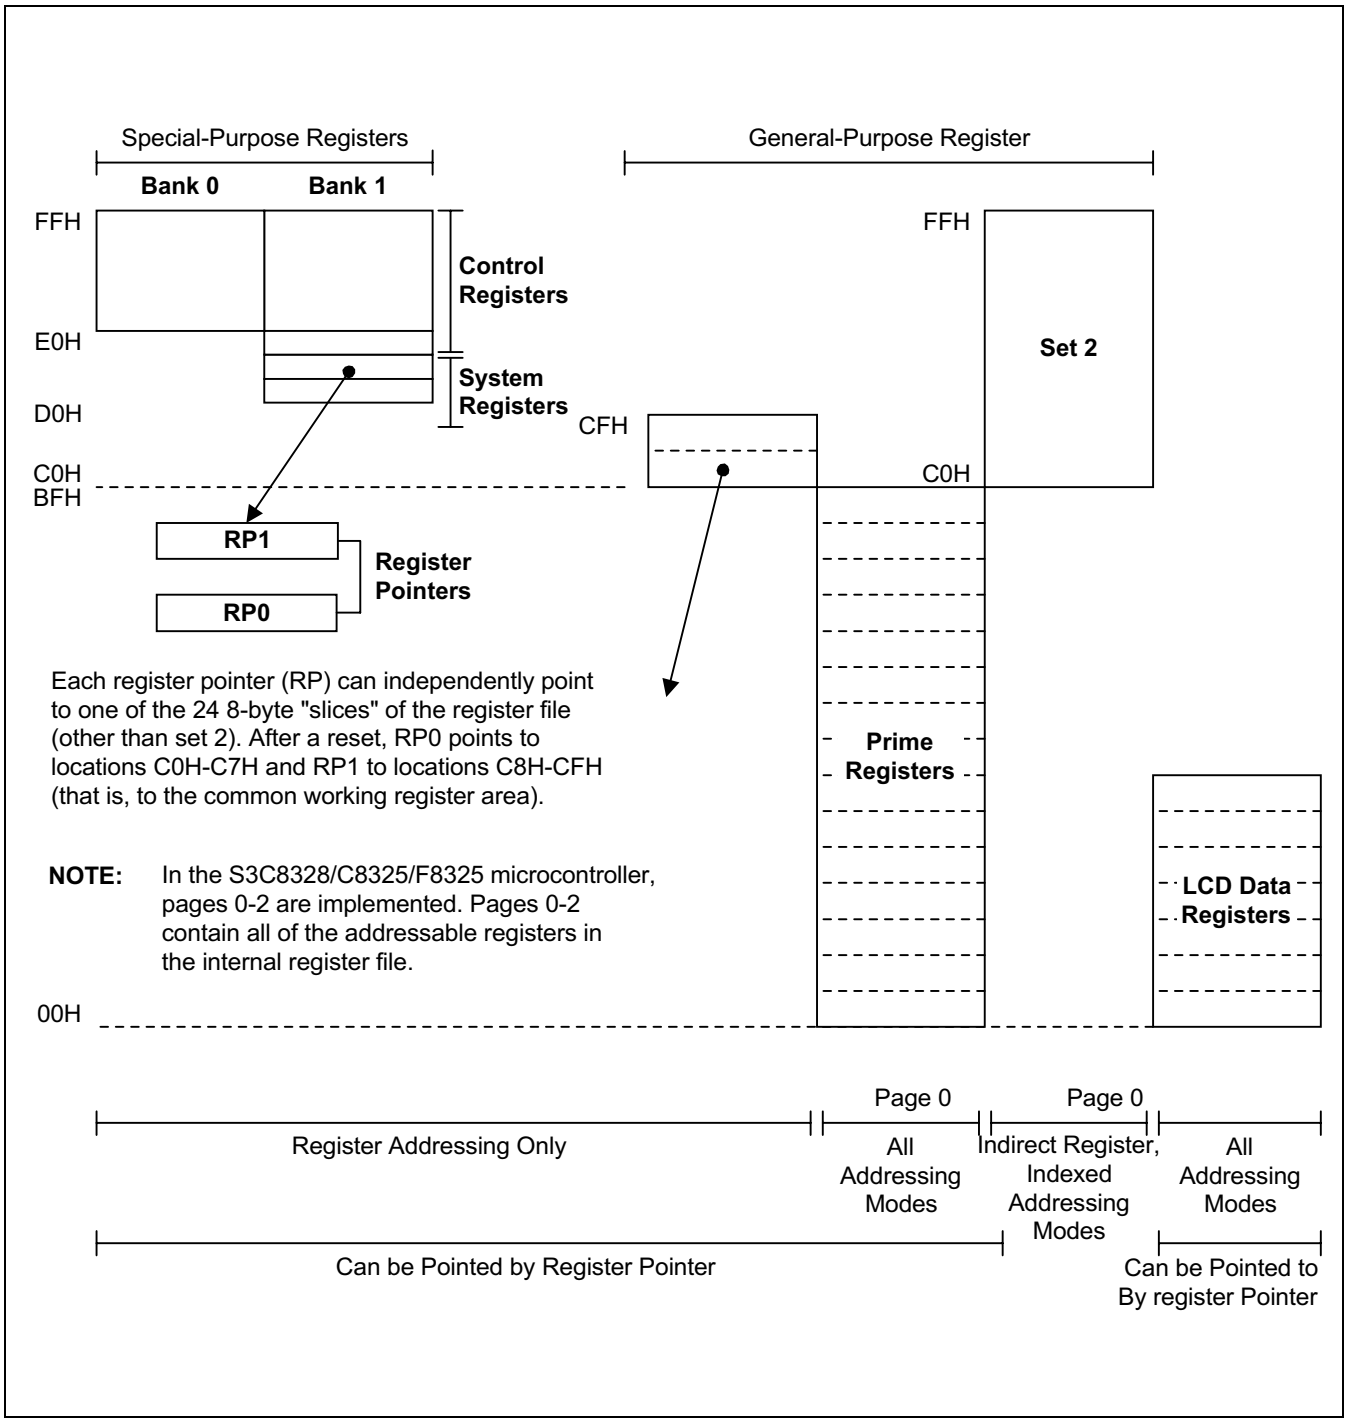

Figure 2-10. Register File Addressing

COMMON WORKING REGISTER AREA (C0H–CFH)

After a reset, register pointers RP0 and RP1 automatically select two 8-byte register slices in set 1, locations C0H–CFH, as the active 16-byte working register block:

RP0 → C0H–C7H

RP1 → C8H–CFH

This 16-byte address range is called *common area*. That is, locations in this area can be used as working registers by operations that address any location on any page in the register file. Typically, these working registers serve as temporary buffers for data operations between different pages.

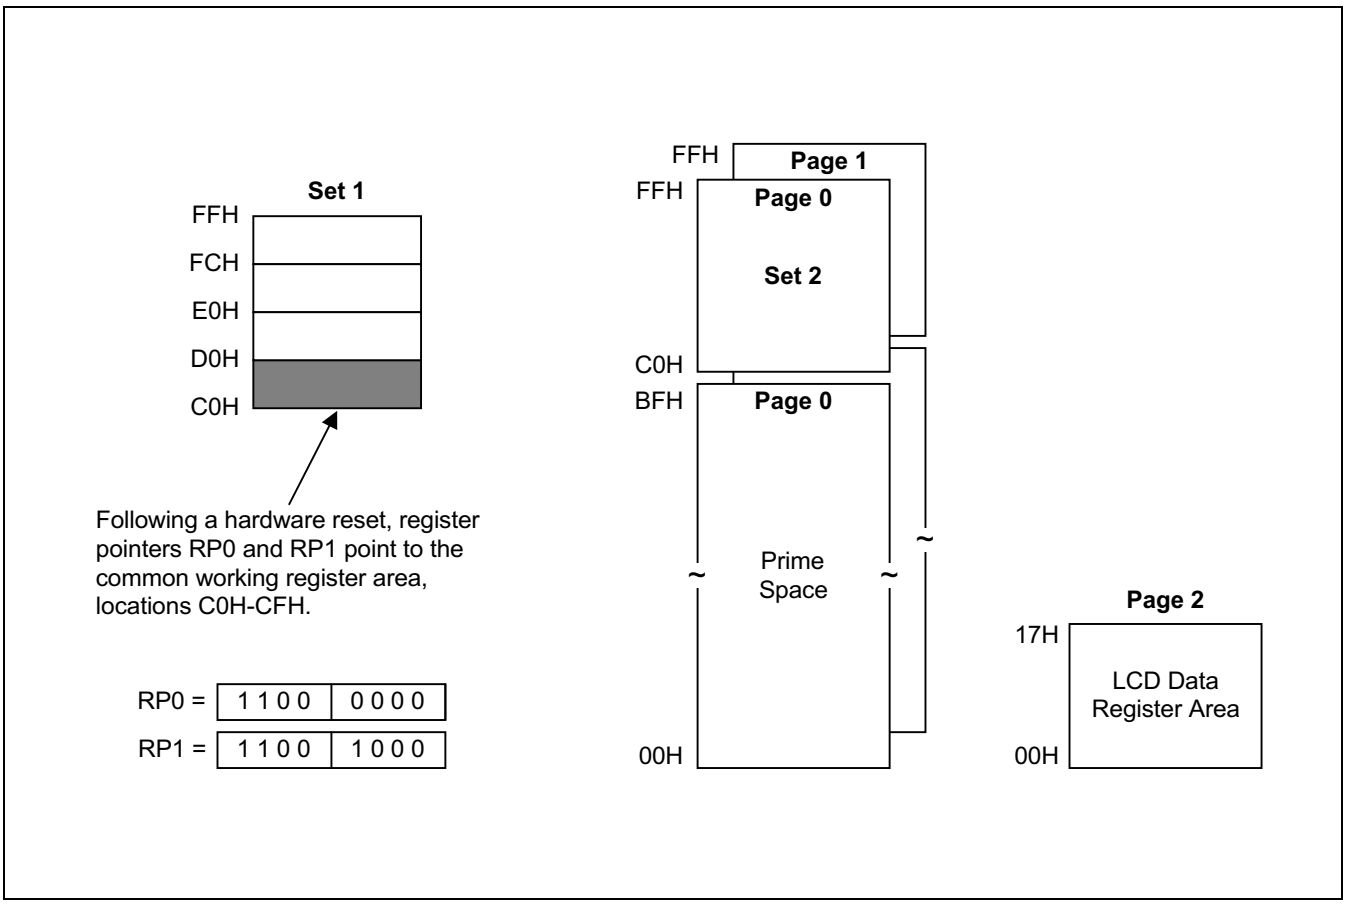

Figure 2-11. Common Working Register Area

☞ PROGRAMMING TIP — Addressing the Common Working Register Area

As the following examples show, you should access working registers in the common area, locations C0H–CFH, using working register addressing mode only.

Examples 1. LD 0C2H,40H ; Invalid addressing mode!

Use working register addressing instead:

```
SRP   #0C0H
LD    R2,40H        ; R2 (C2H) → the value in location 40H
```

2. ADD 0C3H,#45H ; Invalid addressing mode!

Use working register addressing instead:

```
SRP   #0C0H
ADD   R3,#45H       ; R3 (C3H) → R3 + 45H
```

4-BIT WORKING REGISTER ADDRESSING

Each register pointer defines a movable 8-byte slice of working register space. The address information stored in a register pointer serves as an addressing "window" that makes it possible for instructions to access working registers very efficiently using short 4-bit addresses. When an instruction addresses a location in the selected working register area, the address bits are concatenated in the following way to form a complete 8-bit address:

— The high-order bit of the 4-bit address selects one of the register pointers ("0" selects RP0, "1" selects RP1).

— The five high-order bits in the register pointer select an 8-byte slice of the register space.

— The three low-order bits of the 4-bit address select one of the eight registers in the slice.

As shown in Figure 2-11, the result of this operation is that the five high-order bits from the register pointer are concatenated with the three low-order bits from the instruction address to form the complete address. As long as the address stored in the register pointer remains unchanged, the three bits from the address will always point to an address in the same 8-byte register slice.

Figure 2-12 shows a typical example of 4-bit working register addressing. The high-order bit of the instruction "INC R6" is "0", which selects RP0. The five high-order bits stored in RP0 (01110B) are concatenated with the three low-order bits of the instruction's 4-bit address (110B) to produce the register address 76H (01110110B).

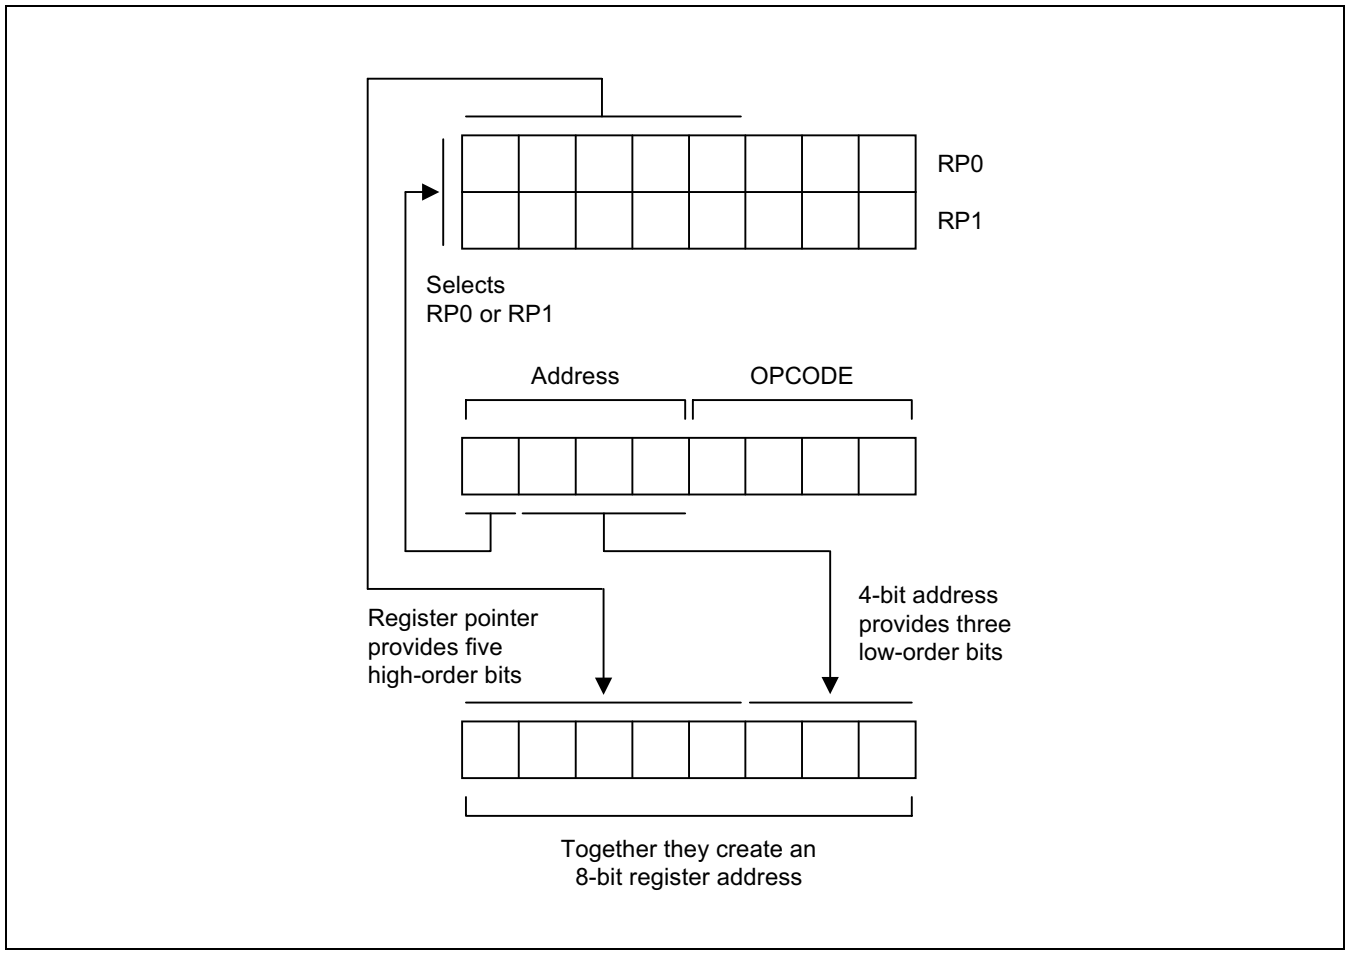

Figure 2-12. 4-Bit Working Register Addressing

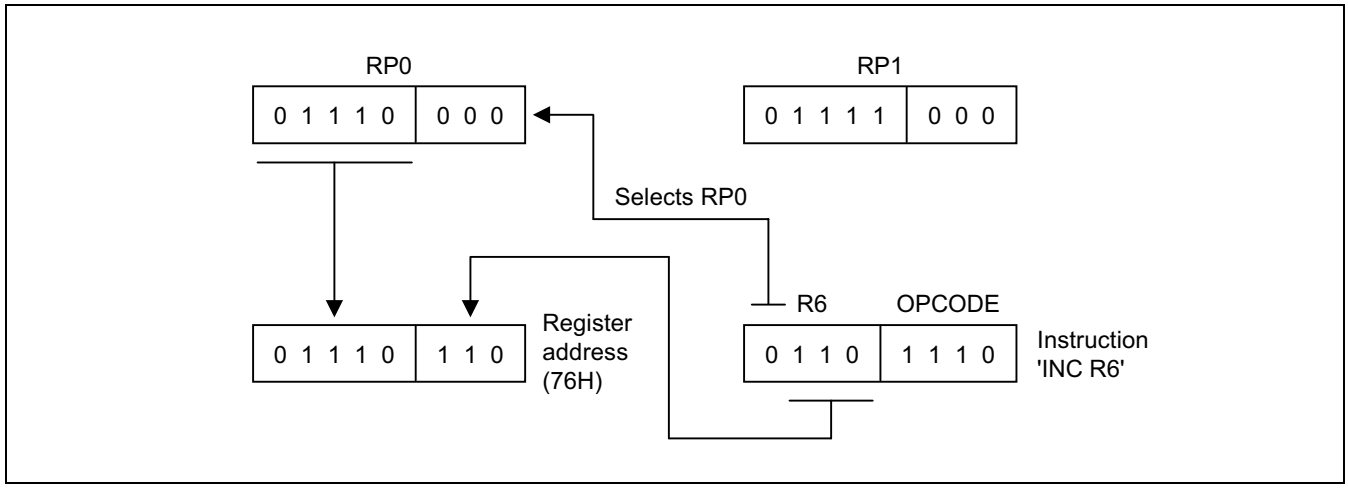

Figure 2-13. 4-Bit Working Register Addressing Example

8-BIT WORKING REGISTER ADDRESSING

You can also use 8-bit working register addressing to access registers in a selected working register area. To initiate 8-bit working register addressing, the upper four bits of the instruction address must contain the value "1100B." This 4-bit value (1100B) indicates that the remaining four bits have the same effect as 4-bit working register addressing.

As shown in Figure 2-13, the lower nibble of the 8-bit address is concatenated in much the same way as for 4-bit addressing: Bit 3 selects either RP0 or RP1, which then supplies the five high-order bits of the final address; the three low-order bits of the complete address are provided by the original instruction.

Figure 2-14 shows an example of 8-bit working register addressing. The four high-order bits of the instruction address (1100B) specify 8-bit working register addressing. Bit 4 ("1") selects RP1 and the five high-order bits in RP1 (10101B) become the five high-order bits of the register address. The three low-order bits of the register address (011) are provided by the three low-order bits of the 8-bit instruction address. The five address bits from RP1 and the three address bits from the instruction are concatenated to form the complete register address, 0ABH (10101011B).

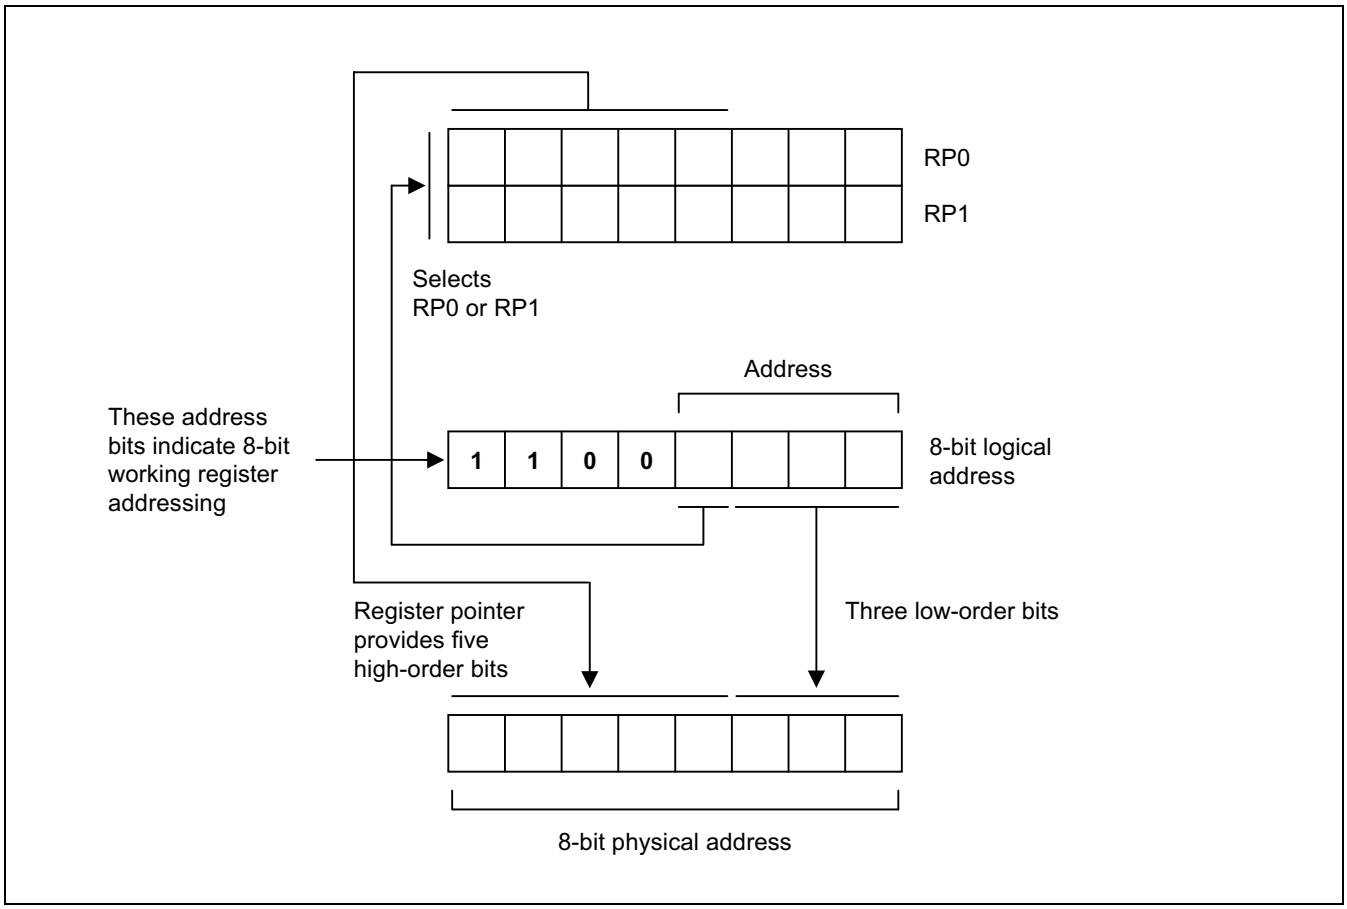

Figure 2-14. 8-Bit Working Register Addressing

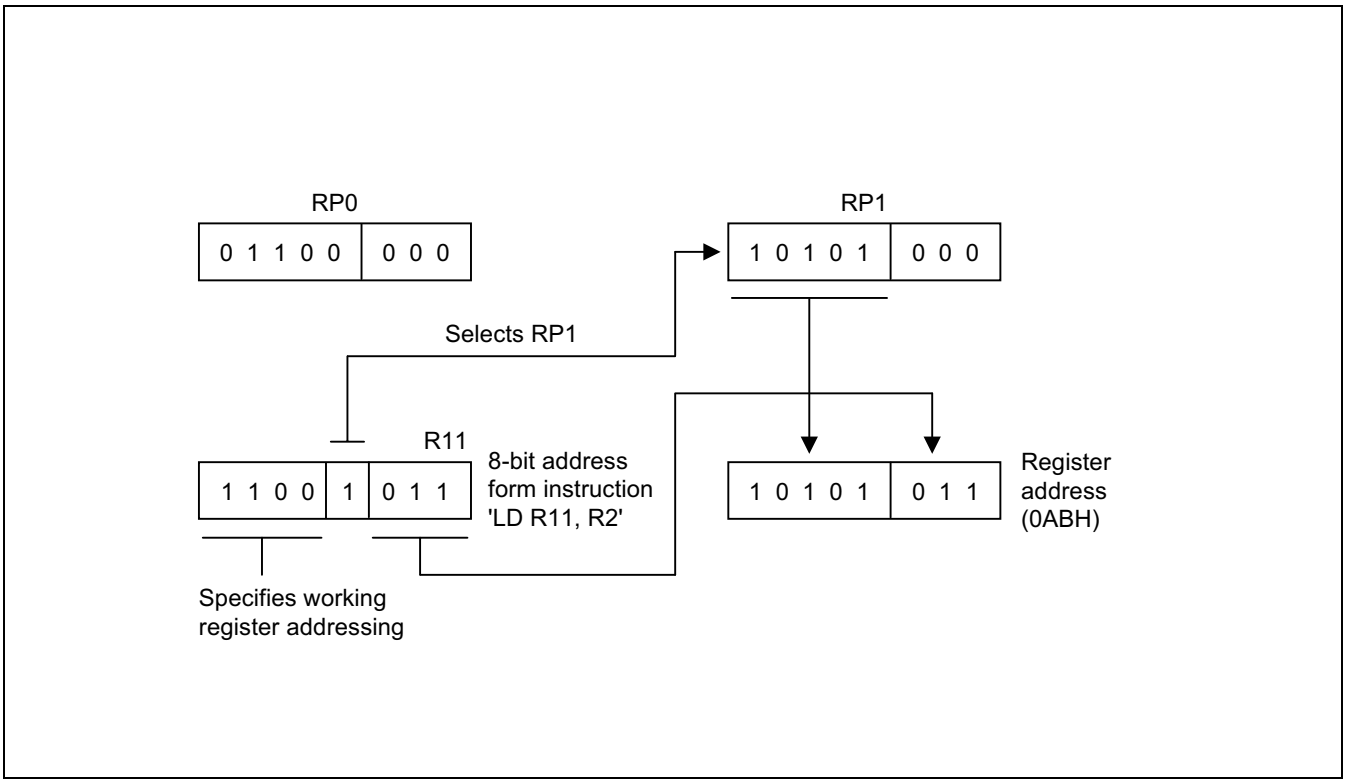

Figure 2-15. 8-Bit Working Register Addressing Example

SYSTEM AND USER STACK

The S3C8-series microcontrollers use the system stack for data storage, subroutine calls and returns. The PUSH and POP instructions are used to control system stack operations. The S3C8238/C8235 architecture supports stack operations in the internal register file.

Stack Operations

Return addresses for procedure calls, interrupts, and data are stored on the stack. The contents of the PC are saved to stack by a CALL instruction and restored by the RET instruction. When an interrupt occurs, the contents of the PC and the FLAGS register are pushed to the stack. The IRET instruction then pops these values back to their original locations. The stack address value is always decreased by one before a push operation and increased by one *after* a pop operation. The stack pointer (SP) always points to the stack frame stored on the top of the stack, as shown in Figure 2-16.

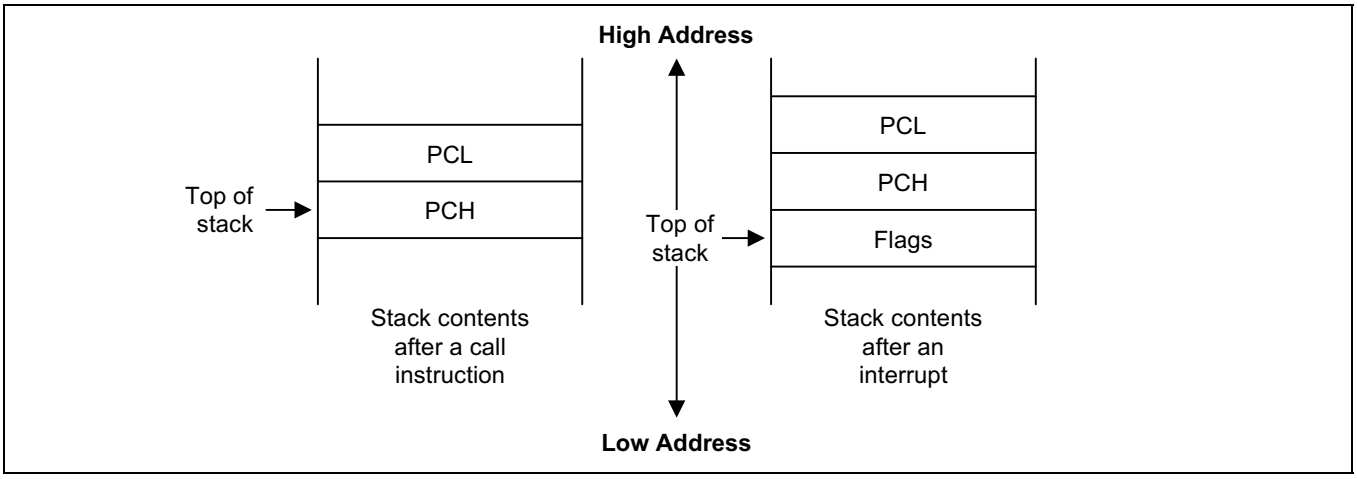

Figure 2-16. Stack Operations

User-Defined Stacks

You can freely define stacks in the internal register file as data storage locations. The instructions PUSHUI, PUSHUD, POPUI, and POPUD support user-defined stack operations.

Stack Pointers (SPL, SPH)

Register locations D8H and D9H contain the 16-bit stack pointer (SP) that is used for system stack operations. The most significant byte of the SP address, SP15–SP8, is stored in the SPH register (D8H), and the least significant byte, SP7–SP0, is stored in the SPL register (D9H). After a reset, the SP value is undetermined.

Because only internal memory space is implemented in the S3C8238/C8235/F8235, the SPL must be initialized to an 8-bit value in the range 00H–FFH. The SPH register is not needed and can be used as a general-purpose register, if necessary.

When the SPL register contains the only stack pointer value (that is, when it points to a system stack in the register file), you can use the SPH register as a general-purpose data register. However, if an overflow or underflow condition occurs as a result of increasing or decreasing the stack address value in the SPL register during normal stack operations, the value in the SPL register will overflow (or underflow) to the SPH register, overwriting any other data that is currently stored there. To avoid overwriting data in the SPH register, you can initialize the SPL value to "FFH" instead of "00H".

☞ PROGRAMMING TIP — Standard Stack Operations Using PUSH and POP

The following example shows you how to perform stack operations in the internal register file using PUSH and POP instructions:

```
LD      SPL,#0FFH       ; SPL ← FFH
                        ; (Normally, the SPL is set to 0FFH by the initialization
                        ; routine)
•
•
•
PUSH    PP              ; Stack address 0FEH ← PP
PUSH    RP0             ; Stack address 0FDH ← RP0
PUSH    RP1             ; Stack address 0FCH ← RP1
PUSH    R3              ; Stack address 0FBH ← R3
•
•
•
POP     R3              ; R3 ← Stack address 0FBH
POP     RP1             ; RP1 ← Stack address 0FCH
POP     RP0             ; RP0 ← Stack address 0FDH
POP     PP              ; PP ← Stack address 0FEH
```

3 ADDRESSING MODES

OVERVIEW

Instructions that are stored in program memory are fetched for execution using the program counter. Instructions indicate the operation to be performed and the data to be operated on. Addressing mode is the method used to determine the location of the data operand. The operands specified in SAM88RC instructions may be condition codes, immediate data, or a location in the register file, program memory, or data memory.

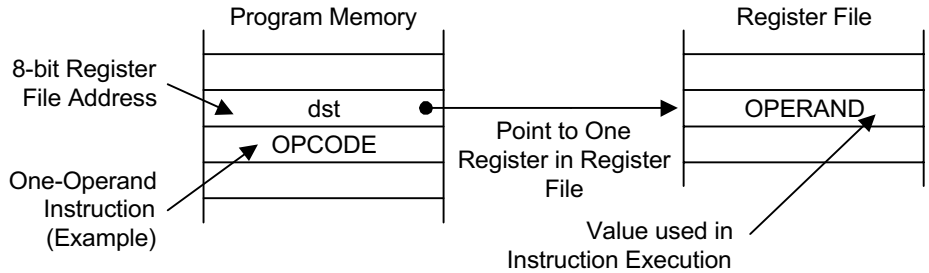
The S3C-series instruction set supports seven explicit addressing modes. Not all of these addressing modes are available for each instruction. The seven addressing modes and their symbols are:

— Register (R)
— Indirect Register (IR)
— Indexed (X)
— Direct Address (DA)
— Indirect Address (IA)
— Relative Address (RA)
— Immediate (IM)

REGISTER ADDRESSING MODE (R)

In Register addressing mode (R), the operand value is the content of a specified register or register pair (see Figure 3-1).

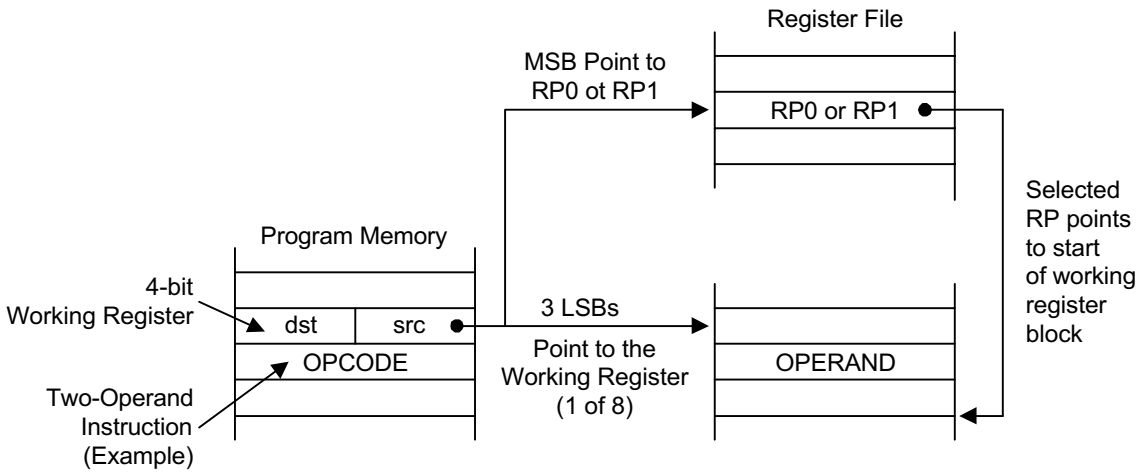
Working register addressing differs from Register addressing in that it uses a register pointer to specify an 8-byte working register space in the register file and an 8-bit register within that space (see Figure 3-2).



Sample Instruction:

```
DEC     CNTR            ;   Where CNTR is the label of an 8-bit register address
```

Figure 3-1. Register Addressing



Sample Instruction:

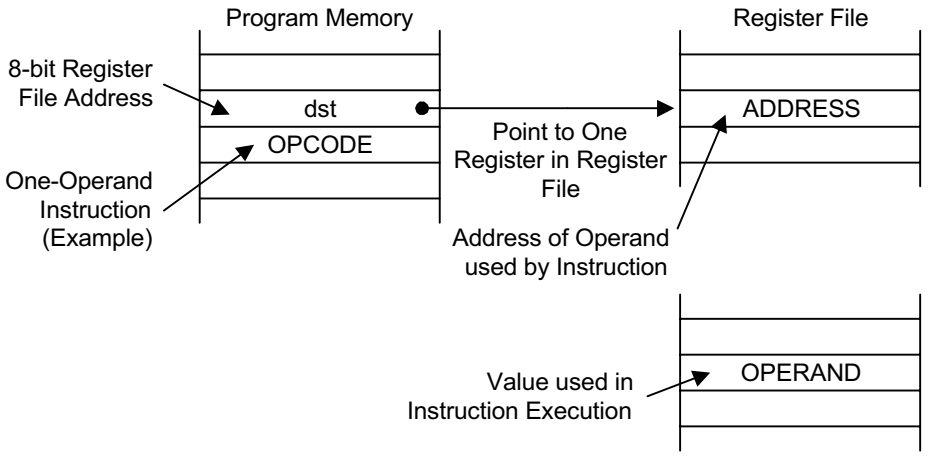
```
ADD     R1, R2          ;   Where R1 and R2 are registers in the currently
                            selected working register area.
```

Figure 3-2. Working Register Addressing

INDIRECT REGISTER ADDRESSING MODE (IR)

In Indirect Register (IR) addressing mode, the content of the specified register or register pair is the address of the operand. Depending on the instruction used, the actual address may point to a register in the register file, to program memory (ROM), or to an external memory space (see Figures 3-3 through 3-6).

You can use any 8-bit register to indirectly address another register. Any 16-bit register pair can be used to indirectly address another memory location. Please note, however, that you cannot access locations C0H–FFH in set 1 using the Indirect Register addressing mode.



Sample Instruction:

```
RL      @SHIFT          ;   Where SHIFT is the label of an 8-bit register address
```

Figure 3-3. Indirect Register Addressing to Register File

INDIRECT REGISTER ADDRESSING MODE (Continued)

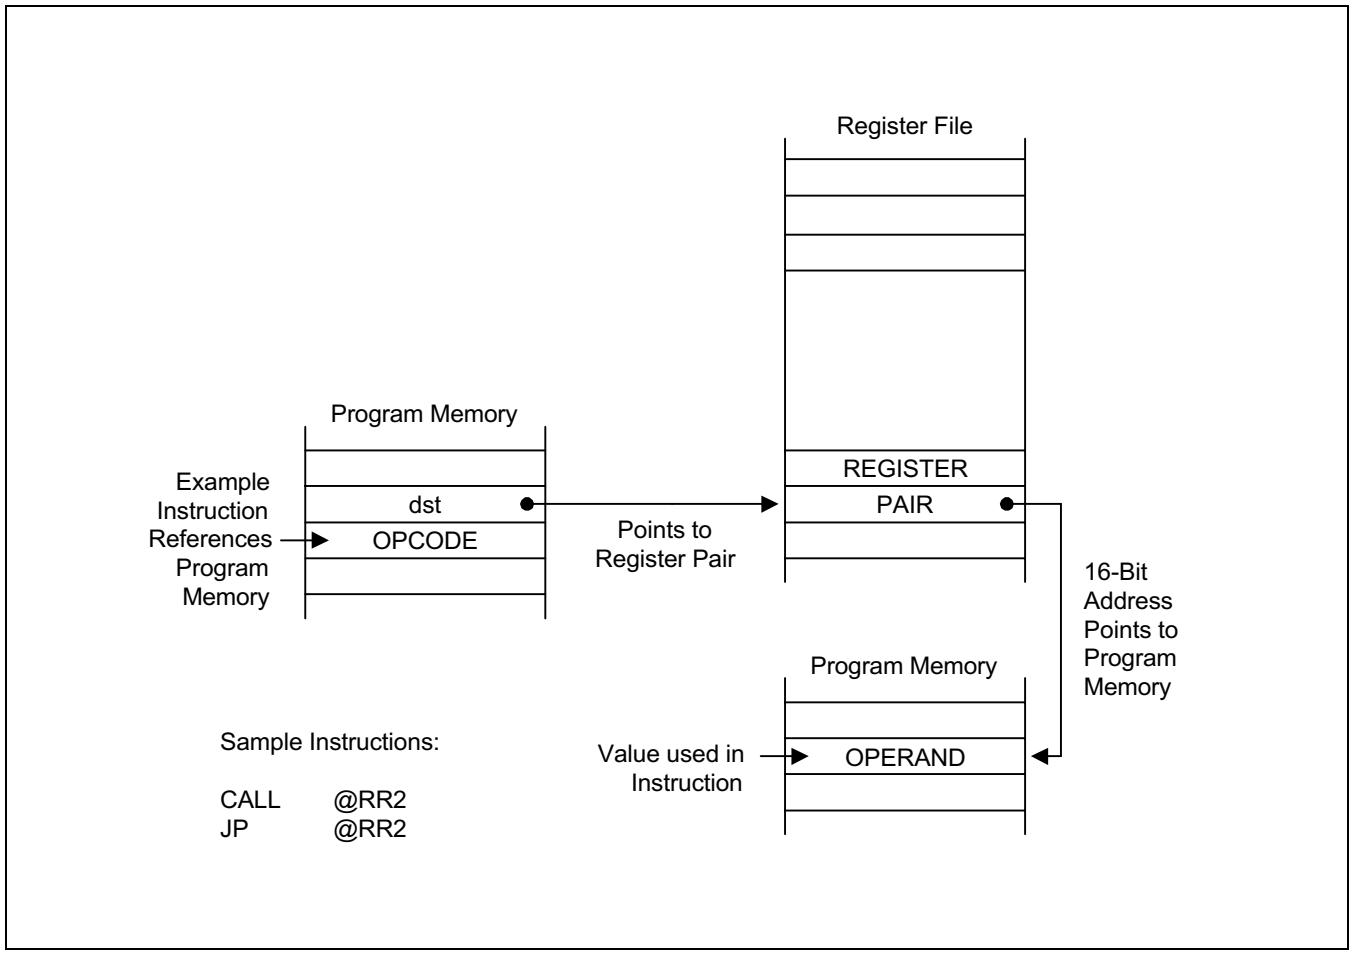


Figure 3-4. Indirect Register Addressing to Program Memory

INDIRECT REGISTER ADDRESSING MODE (Continued)

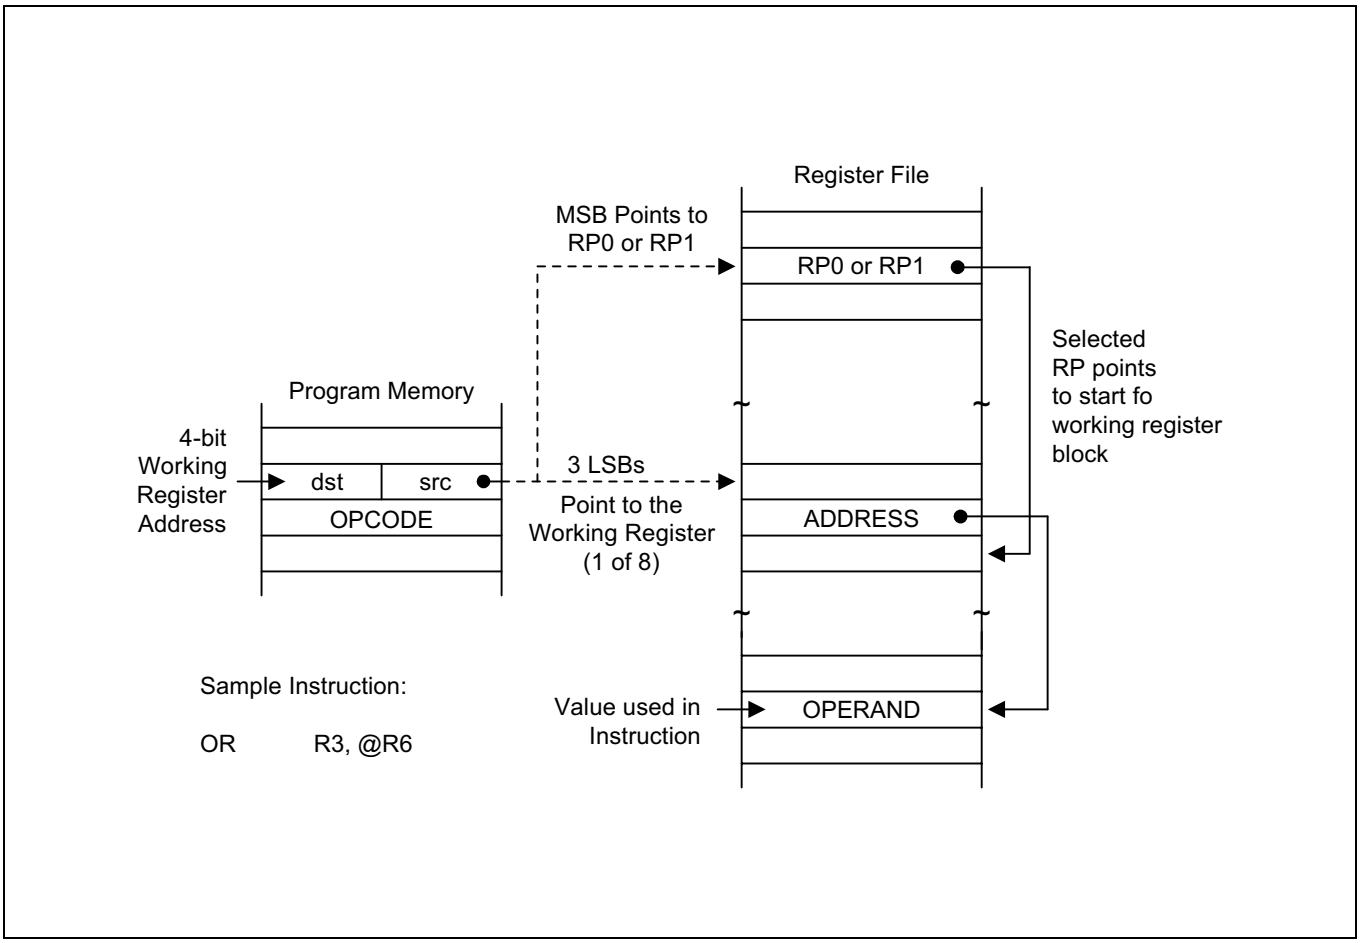

Figure 3-5. Indirect Working Register Addressing to Register File

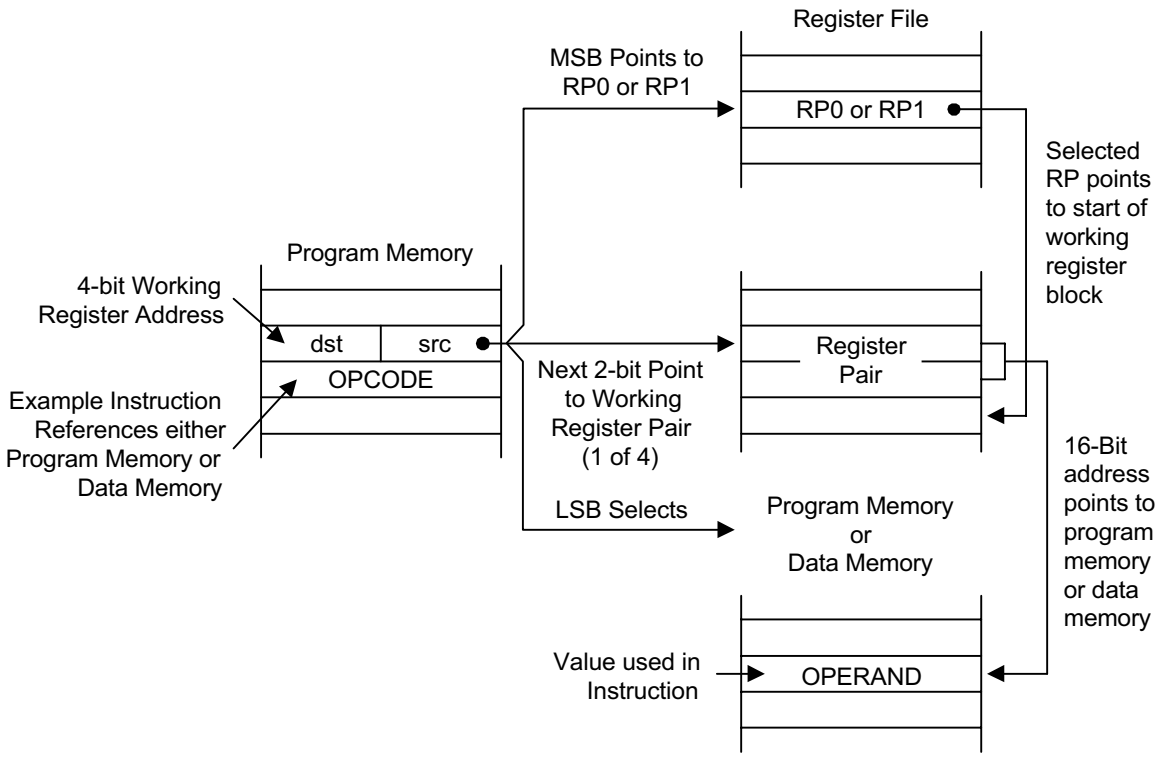
INDIRECT REGISTER ADDRESSING MODE (Concluded)



Sample Instructions:

```
LCD     R5,@RR6      ;  Program memory access
LDE     R3,@RR14     ;  External data memory access
LDE     @RR4, R8     ;  External data memory access
```

Figure 3-6. Indirect Working Register Addressing to Program or Data Memory

INDEXED ADDRESSING MODE (X)

Indexed (X) addressing mode adds an offset value to a base address during instruction execution in order to calculate the effective operand address (see Figure 3-7). You can use Indexed addressing mode to access locations in the internal register file or in external memory. Please note, however, that you cannot access locations C0H–FFH in set 1 using Indexed addressing mode.

In short offset Indexed addressing mode, the 8-bit displacement is treated as a signed integer in the range –128 to +127. This applies to external memory accesses only (see Figure 3-8.)

For register file addressing, an 8-bit base address provided by the instruction is added to an 8-bit offset contained in a working register. For external memory accesses, the base address is stored in the working register pair designated in the instruction. The 8-bit or 16-bit offset given in the instruction is then added to that base address (see Figure 3-9).

The only instruction that supports Indexed addressing mode for the internal register file is the Load instruction (LD). The LDC and LDE instructions support Indexed addressing mode for internal program memory and for external data memory, when implemented.

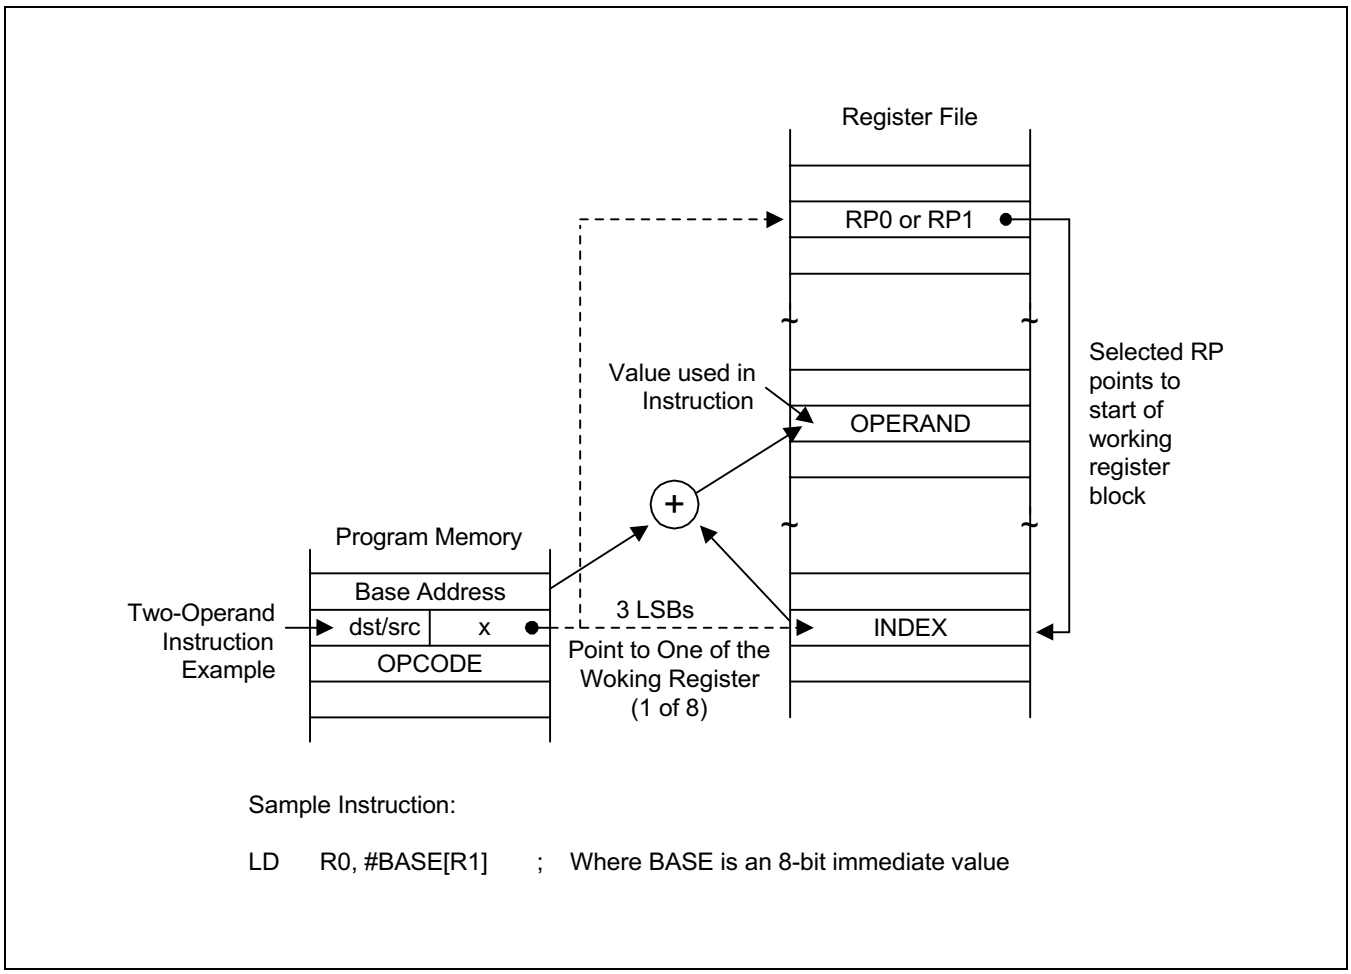


Figure 3-7. Indexed Addressing to Register File

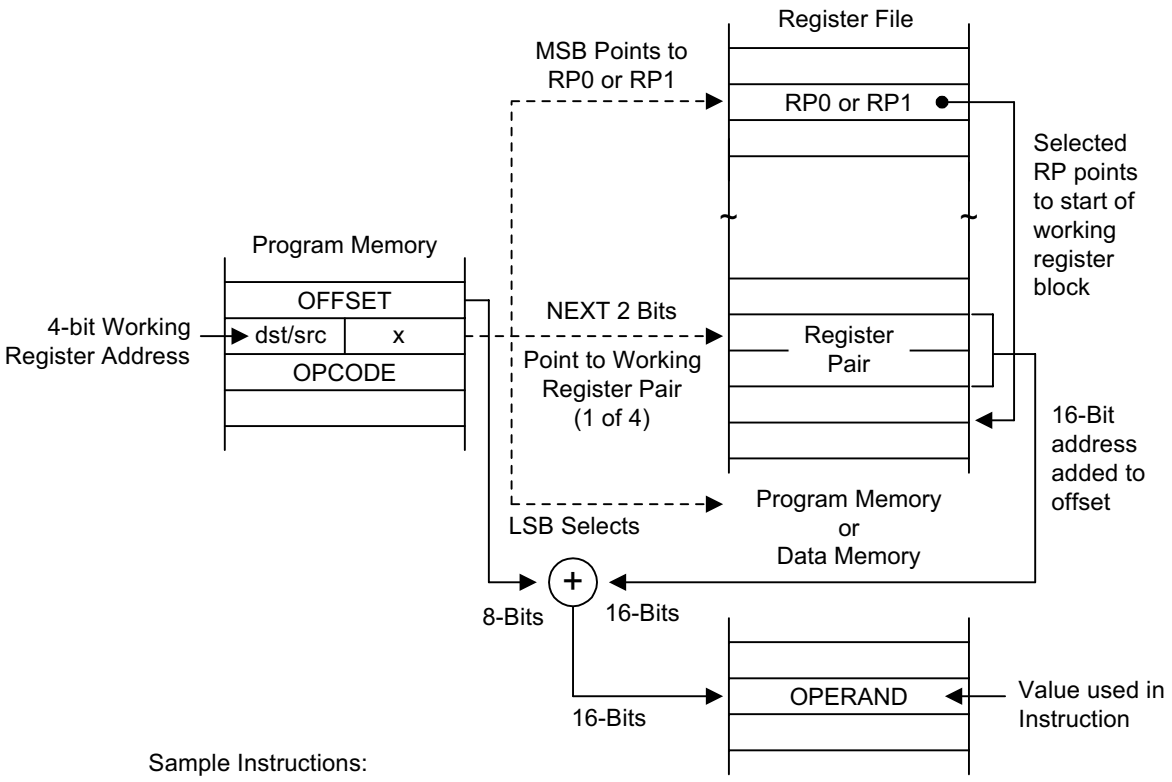
INDEXED ADDRESSING MODE (Continued)

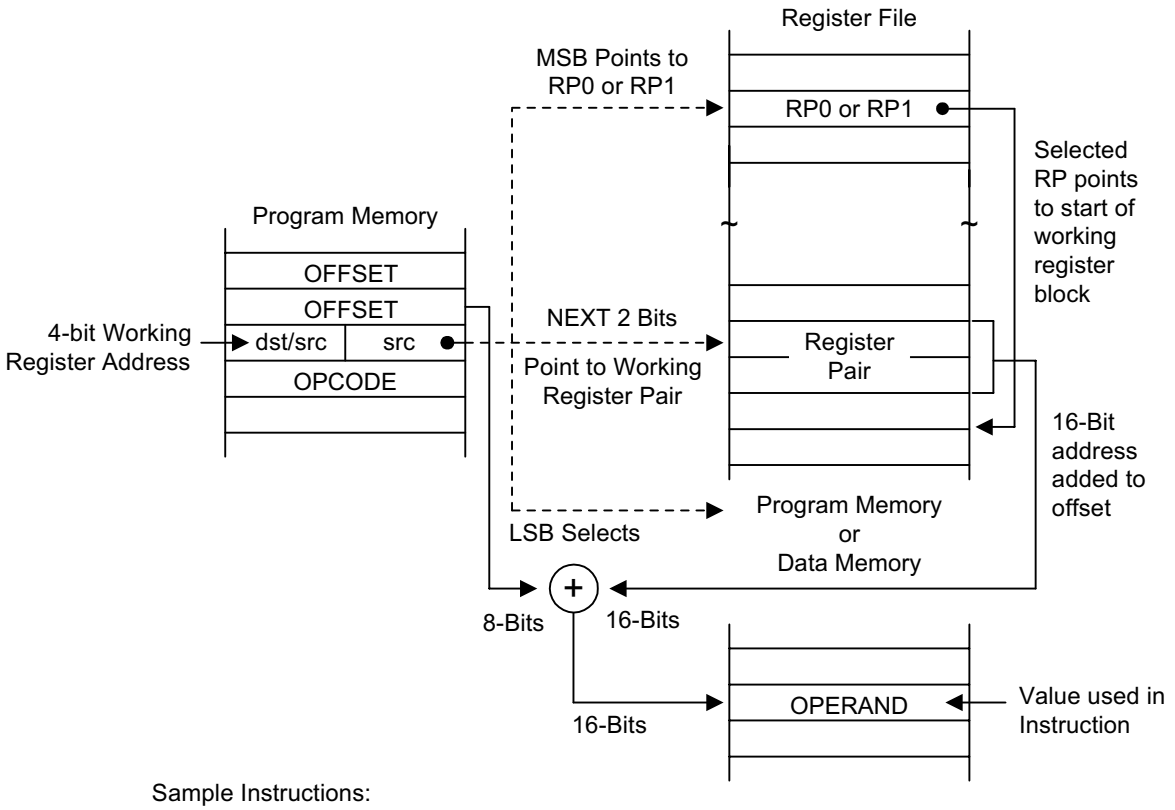


Sample Instructions:

```
LDC     R4, #04H[RR2]     ; The values in the program address (RR2 + 04H)
                          ; are loaded into register R4.
LDE     R4,#04H[RR2]      ; Identical operation to LDC example, except that
                          ; external program memory is accessed.
```

Figure 3-8. Indexed Addressing to Program or Data Memory with Short Offset

INDEXED ADDRESSING MODE (Concluded)



Sample Instructions:

```
LDC     R4, #1000H[RR2]     ; The values in the program address (RR2 + 1000H)
                            ; are loaded into register R4.
LDE     R4,#1000H[RR2]      ; Identical operation to LDC example, except that
                            ; external program memory is accessed.
```

Figure 3-9. Indexed Addressing to Program or Data Memory

DIRECT ADDRESS MODE (DA)

In Direct Address (DA) mode, the instruction provides the operand's 16-bit memory address. Jump (JP) and Call (CALL) instructions use this addressing mode to specify the 16-bit destination address that is loaded into the PC whenever a JP or CALL instruction is executed.

The LDC and LDE instructions can use Direct Address mode to specify the source or destination address for Load operations to program memory (LDC) or to external data memory (LDE), if implemented.

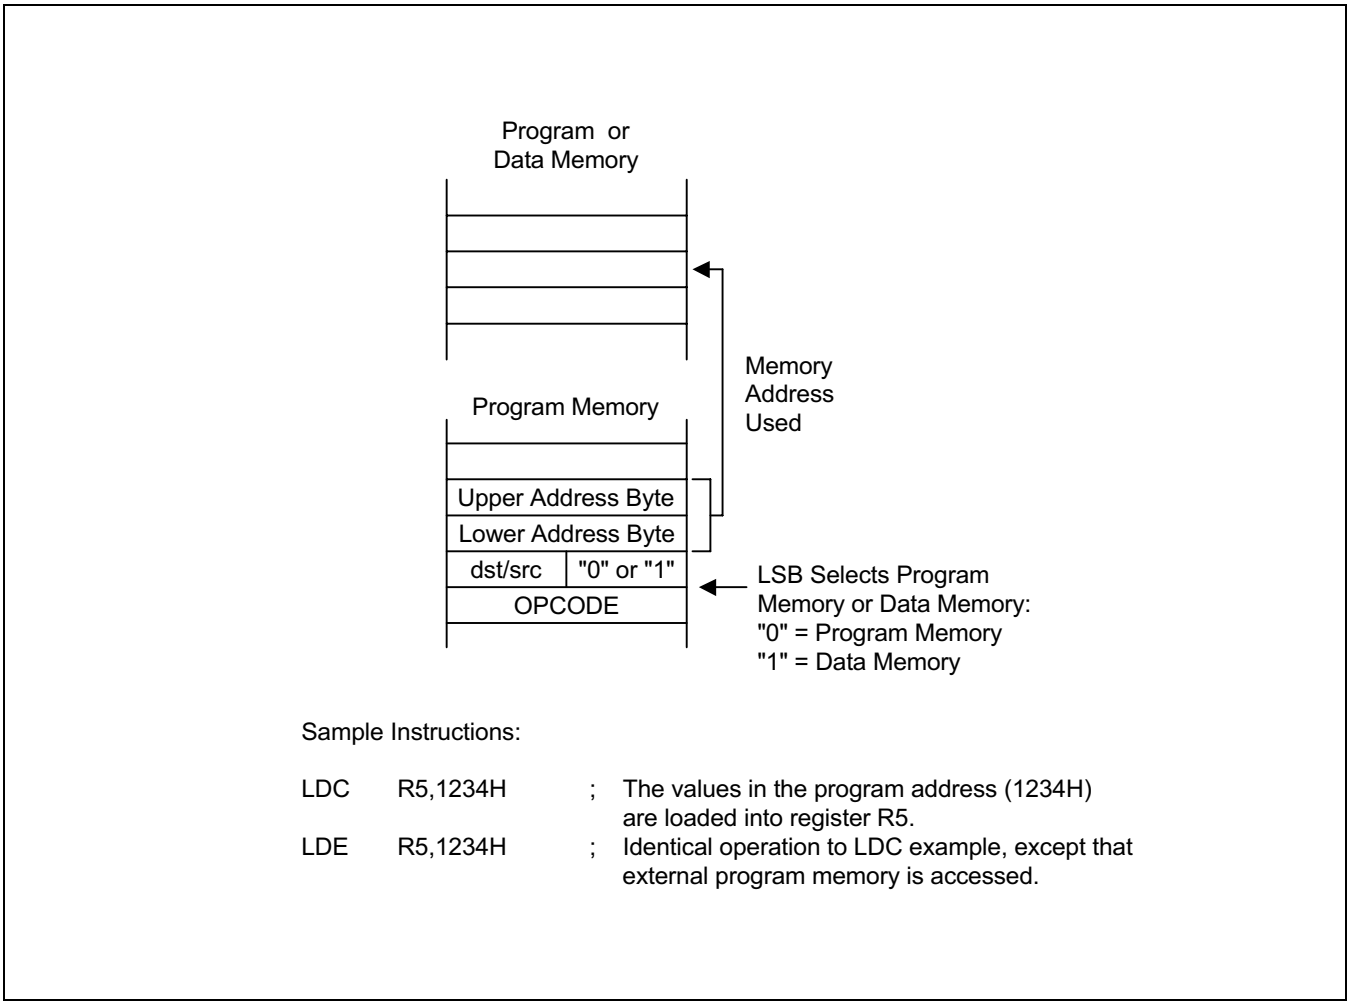


Figure 3-10. Direct Addressing for Load Instructions

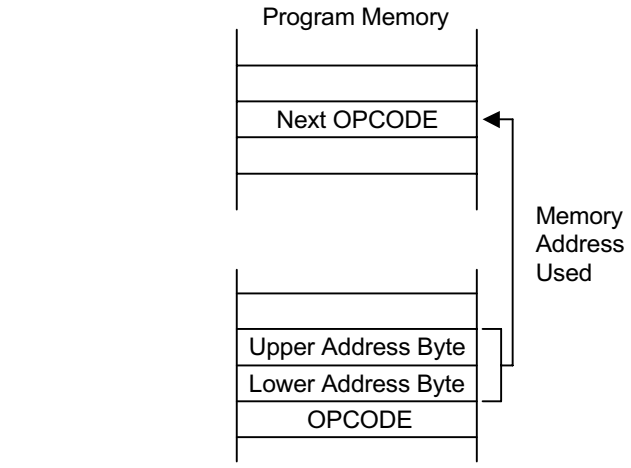
DIRECT ADDRESS MODE (Continued)



Sample Instructions:

```
JP      C,JOB1          ;   Where JOB1 is a 16-bit immediate address
CALL    DISPLAY         ;   Where DISPLAY is a 16-bit immediate address
```

Figure 3-11. Direct Addressing for Call and Jump Instructions

INDIRECT ADDRESS MODE (IA)

In Indirect Address (IA) mode, the instruction specifies an address located in the lowest 256 bytes of the program memory. The selected pair of memory locations contains the actual address of the next instruction to be executed. Only the CALL instruction can use the Indirect Address mode.

Because the Indirect Address mode assumes that the operand is located in the lowest 256 bytes of program memory, only an 8-bit address is supplied in the instruction; the upper bytes of the destination address are assumed to be all zeros.

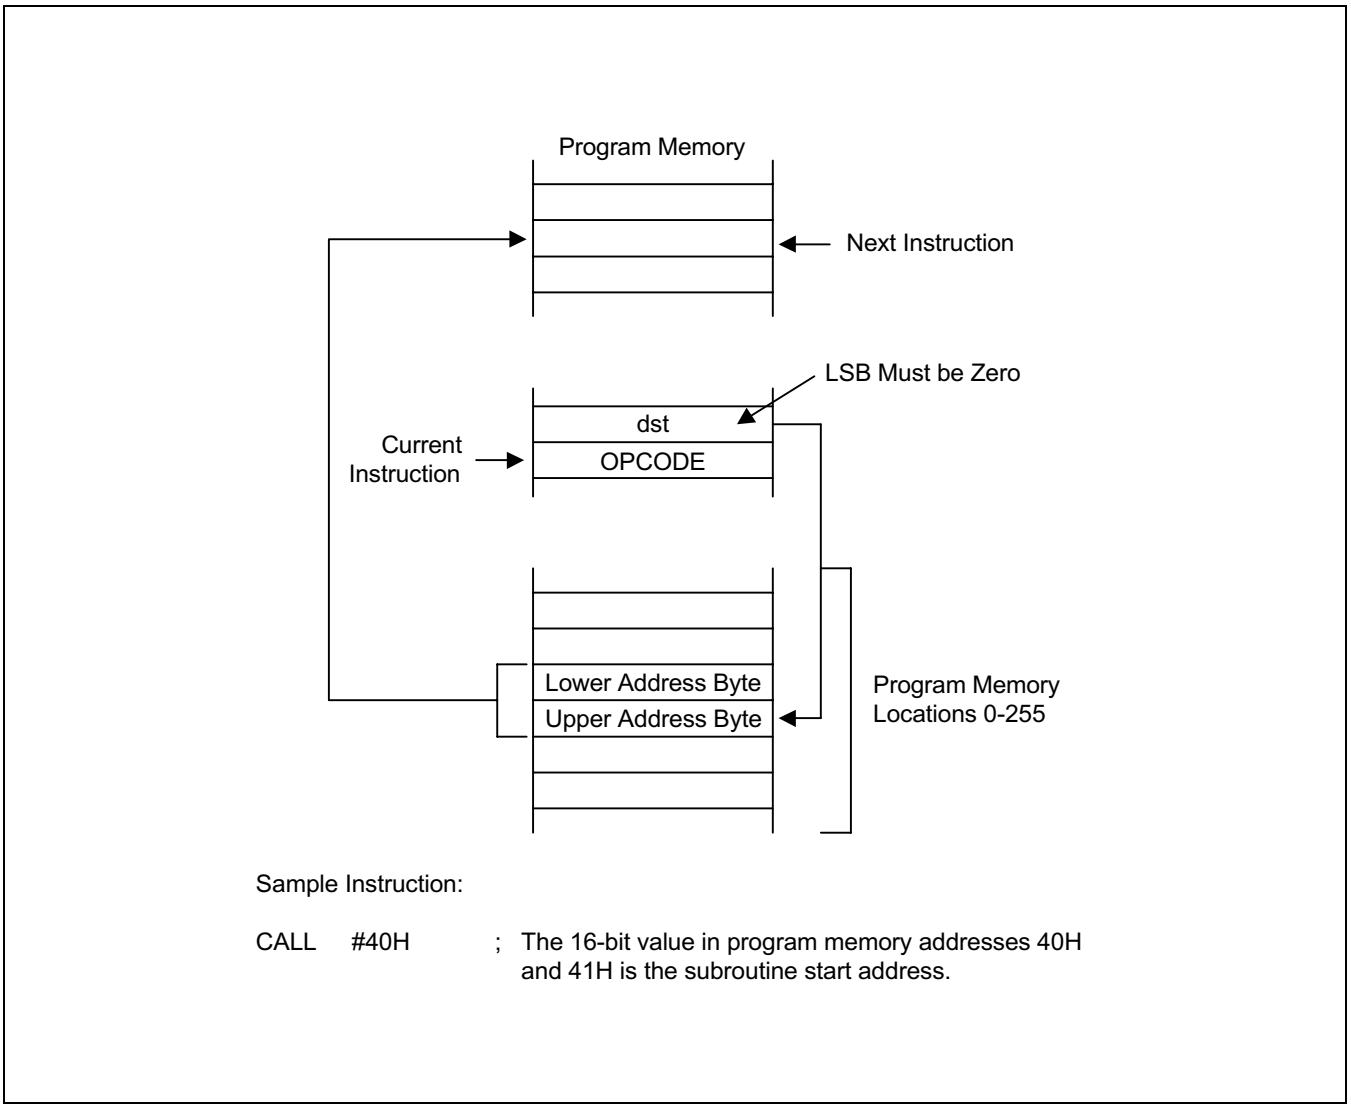


Figure 3-12. Indirect Addressing

RELATIVE ADDRESS MODE (RA)

In Relative Address (RA) mode, a twos-complement signed displacement between – 128 and + 127 is specified in the instruction. The displacement value is then added to the current PC value. The result is the address of the next instruction to be executed. Before this addition occurs, the PC contains the address of the instruction immediately following the current instruction.

Several program control instructions use the Relative Address mode to perform conditional jumps. The instructions that support RA addressing are BTJRF, BTJRT, DJNZ, CPIJE, CPIJNE, and JR.

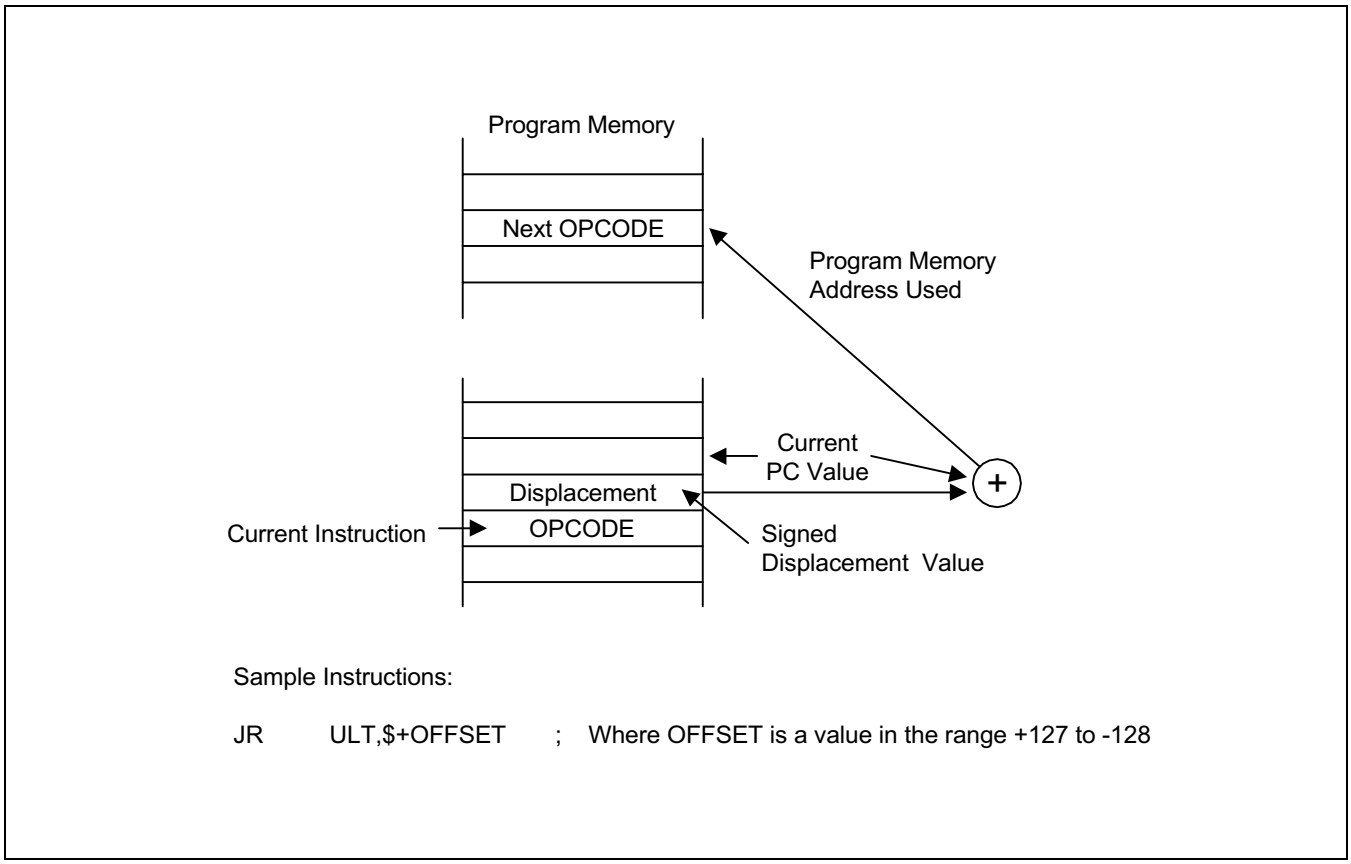

Figure 3-13. Relative Addressing

IMMEDIATE MODE (IM)

In Immediate (IM) addressing mode, the operand value used in the instruction is the value supplied in the operand field itself. The operand may be one byte or one word in length, depending on the instruction used. Immediate addressing mode is useful for loading constant values into registers.

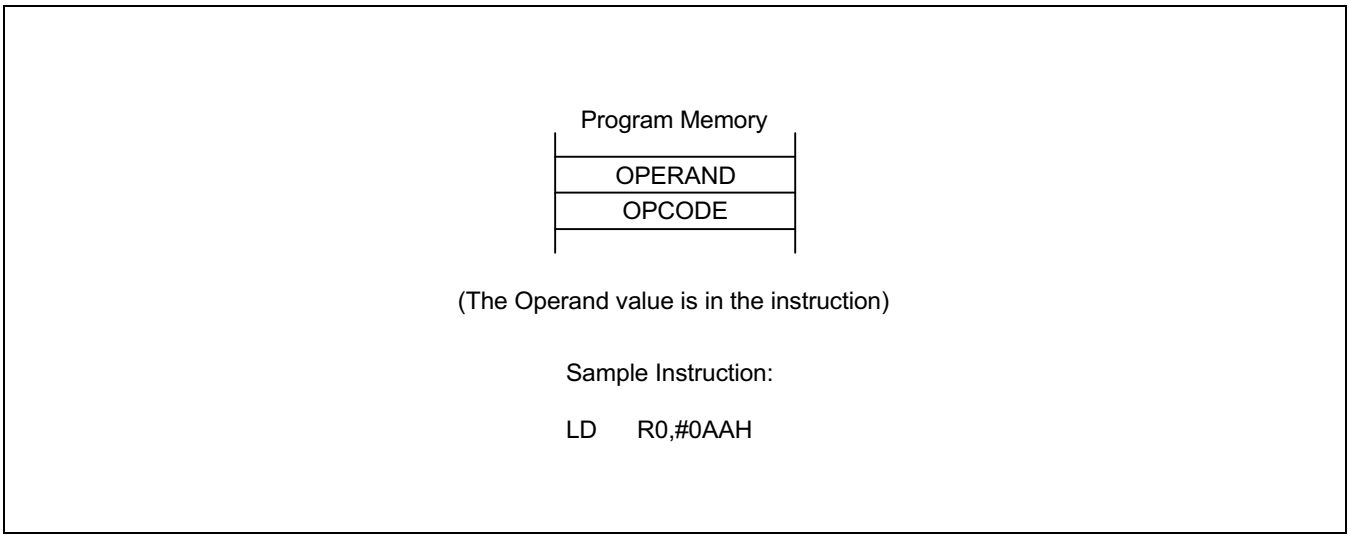

Figure 3-14. Immediate Addressing

4 CONTROL REGISTERS

OVERVIEW

Control register descriptions are arranged in alphabetical order according to register mnemonic. More detailed information about control registers is presented in the context of the specific peripheral hardware descriptions in Part II of this manual.

The locations and read/write characteristics of all mapped registers in the S3C8238/C8235/F8235 register file are listed in Table 4-1. The hardware reset value for each mapped register is described in Chapter 8, "RESET and Power-Down."

Table 4-1. Set 1 Registers

Register Name	Mnemonic	Decimal	Hex	R/W
LCD control register	LCON	208	D0H	R/W
LCD mode register	LMOD	209	D1H	R/W
Location D2H is not mapped.				
Basic timer control register	BTCON	211	D3H	R/W
Clock Control register	CLKCON	222	D4H	R/W
System flags register	FLAGS	213	D5H	R/W
Register pointer 0	RP0	214	D6H	R/W
Register pointer 1	RP1	215	D7H	R/W
Stack pointer (high byte)	SPH	216	D8H	R/W
Stack pointer (low byte)	SPL	217	D9H	R/W
Instruction pointer (high byte)	IPH	218	DAH	R/W
Instruction pointer (low byte)	IPL	219	DBH	R/W
Interrupt request register	IRQ	220	DCH	R
Interrupt mask register	IMR	221	DDH	R/W
System mode register	SYM	222	DEH	R/W
Register page pointer	PP	223	DFH	R/W

Table 4-2. Set 1, Bank 0 Registers

Register Name	Mnemonic	Decimal	Hex	R/W
Port 0 Data Register	P0	224	E0H	R/W
Port 1 Data Register	P1	225	E1H	R/W
Port 2 Data Register	P2	226	E2H	R/W
Port 3 Data Register	P3	227	E3H	R/W
Port 4 Data Register	P4	228	E4H	R/W
Port 0 interrupt control register	P0INT	229	E5H	R/W
Port 0 interrupt pending register	P0PND	230	E6H	R/W
Port 3 interrupt control register	P3INT	231	E7H	R/W
Port 3 interrupt pending register	P3PND	232	E8H	R/W
Timer A/Timer 1 interrupt pending register	TINTPND	233	E9H	R/W
Timer A control register	TACON	234	EAH	R/W
Timer A counter register	TACNT	235	EBH	R
Timer A data register	TADATA	236	ECH	R/W
Timer B control register	TBCON	237	EDH	R/W
Timer B data register(high byte)	TBDATAH	238	EEH	R/W
Timer B data register(low byte)	TBDATAL	239	EFH	R/W
Key strobe data register	KSDATA	240	F0H	R
Voltage level detector control register	VLDCON	241	F1H	R/W
Watch timer control register	WTCON	242	F2H	R/W
Oscillator control register	OSCCON	243	F3H	R/W
STOP Control register	STPCON	244	F4H	R/W
Pattern generation control register	PGCON	245	F5H	R/W

Timer 1 data register 2(low byte)	T1DATA2L	247	F7H	R/W
Timer 1 prescaler register	T1PS	248	F8H	R/W
Locations F9H-FFH are not mapped.				

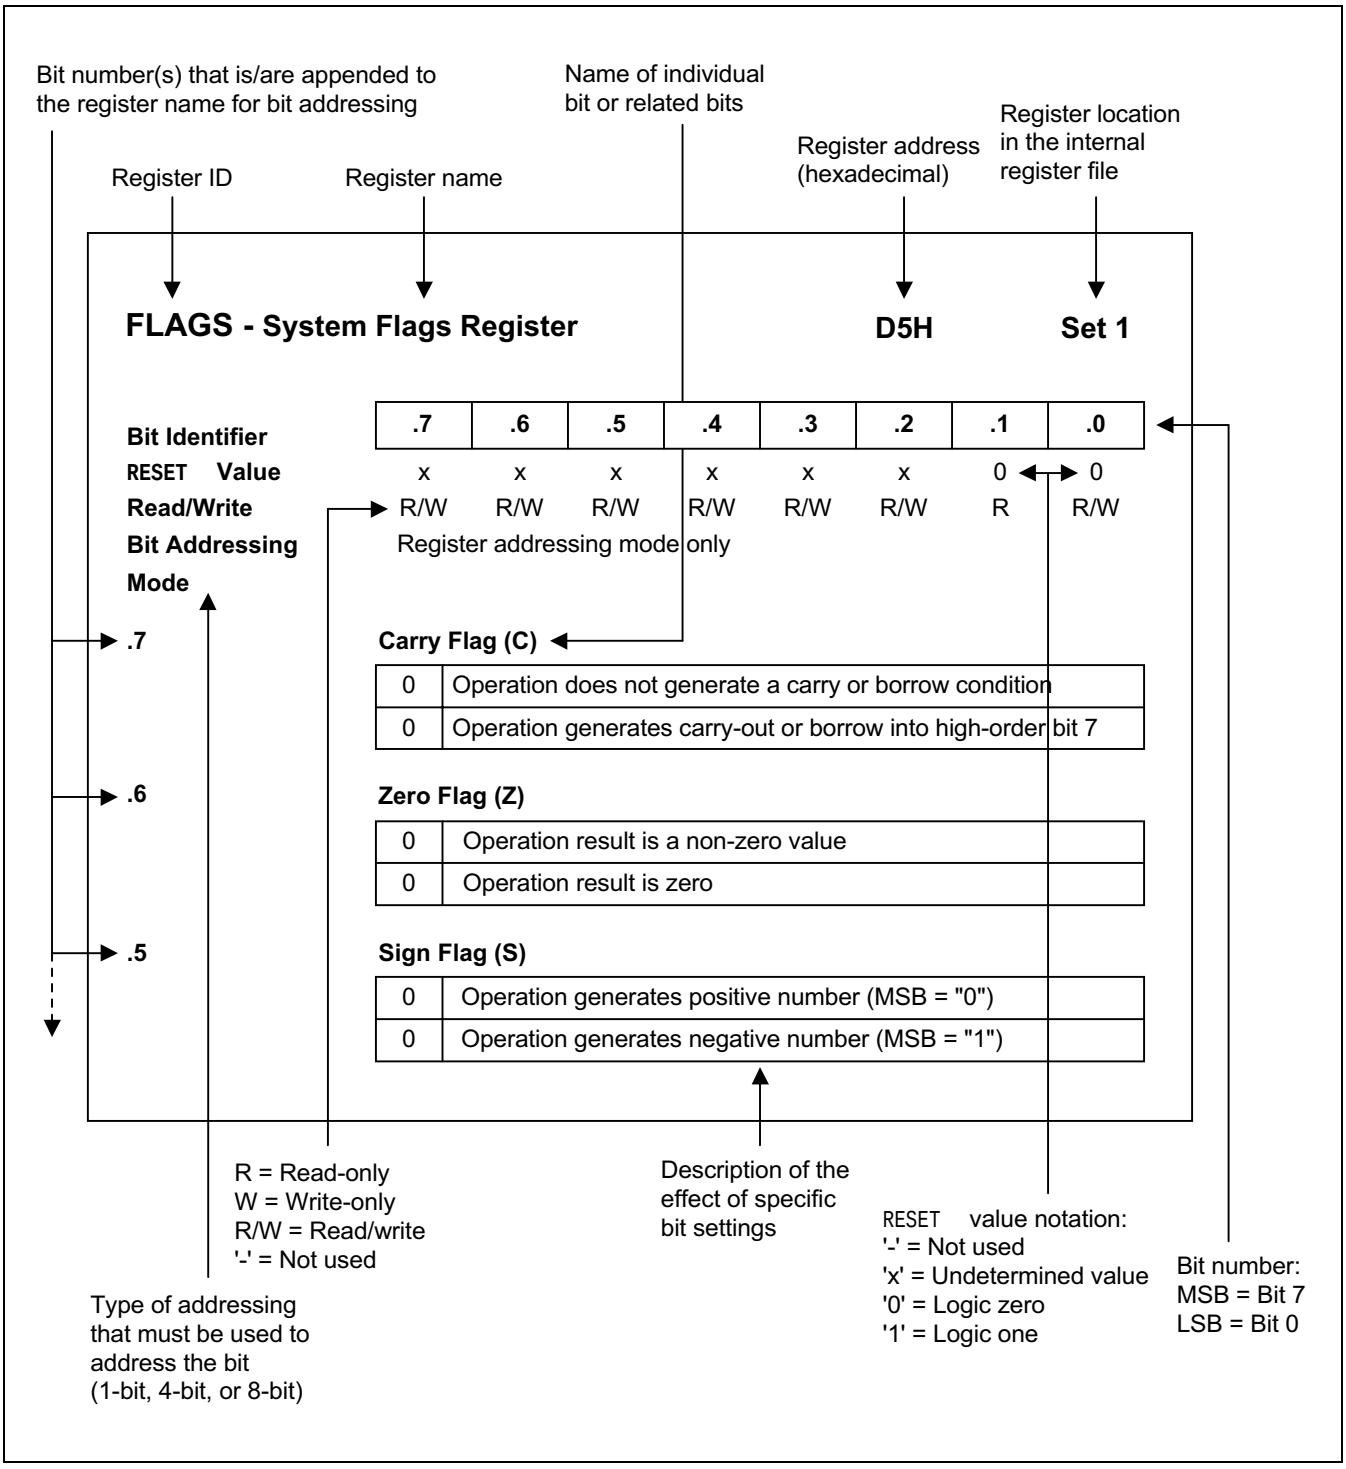

Figure 4-1. Register Description Format

ADCON — A/D Converter Control Register F7H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	0	0	0	0	0	0	0
Read/Write	–	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7

Not used for the S3C8238/C8235/F8235, Always logic zero

.6-.4 A/D Input Pin Selection Bits

0	0	0	ADC0
0	0	1	ADC1
0	1	0	ADC2
0	1	1	ADC3
1	0	0	ADC4
1	0	1	ADC5
1	1	0	ADC6
1	1	1	ADC7

.3 ADC Interrupt Enable Bit

0	ADC interrupt disable
1	ADC interrupt enable

.2-.1 Clock Source Selection Bits

0	0	fxx/16
0	1	fxx/8
1	0	fxx/4
1	1	fxx

.0 Start or Enable Bit

0	Disable operation
1	Start operation

ADINT — A/D Conversion Interrupt Register FAH Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	–	–	–	–	–	–	0
Read/Write	–	–	–	–	–	–	–	R/W
Addressing Mode	Register addressing mode only							

.7-.1

Not used for the S3C8238/C8235/F8235

.0

Interrupt Pending Bits (or EOC)

0	Interrupt is not pending (When reading) Clear pending bit (When writing)
1	Interrupt is pending (When reading)

BTCON — Basic Timer Control Register D3H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.4 Watchdog Timer Function Disable Code (for System Reset)

1	0	1	0	Disable watchdog timer function
Others				Enable watchdog timer function

.3-.2 Basic Timer Input Clock Selection Bits

0	0	fxx/4096 (3)
0	1	fxx/1024
1	0	fxx/128
1	1	Not used

.1 Basic Timer Counter Clear Bit (1)

0	No effect
1	Clear the basic timer counter value

.0 Clock Frequency Divider Clear Bit for Basic Timer (2)

0	No effect
1	Clear both clock frequency dividers

NOTES:

1. When you write a “1” to BTCON.1, the basic timer counter value is cleared to "00H". Immediately following the write operation, the BTCON.1 value is automatically cleared to “0”.
2. When you write a "1" to BTCON.0, the corresponding frequency divider is cleared to "00H". Immediately following the write operation, the BTCON.0 value is automatically cleared to "0".
3. The fxx is selected clock for system (main OSC. or sub OSC.).

CLKCON — System Clock Control Register D4H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	–	–	–	R/W	R/W	–	–	–
Addressing Mode	Register addressing mode only							

.7-.5 Not used for the S3C8238/C8235/F8235 (always logic zero)

.4-.3 **CPU Clock (System Clock) Selection Bits** (note)

0	0	fxx/16
0	1	fxx/8
1	0	fxx/2
1	1	fxx/1 (non-divided)

.2-.0 Not used for the S3C8238/C8235/F8235 (always logic zero)

NOTE: After a reset, the slowest clock (divided by 16) is selected as the system clock. To select faster clock speeds, load the appropriate values to CLKCON.3 and CLKCON.4.

FLAGS — System Flags Register D5H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W
Addressing Mode	Register addressing mode only							

.7 Carry Flag (C)

0	Operation does not generate a carry or underflow condition
1	Operation generates a carry-out or underflow into high-order bit 7

.6 Zero Flag (Z)

0	Operation result is a non-zero value
1	Operation result is zero

.5 Sign Flag (S)

0	Operation generates a positive number (MSB = "0")
1	Operation generates a negative number (MSB = "1")

.4 Overflow Flag (V)

0	Operation result is $\leq$ +127 or $\geq$ –128
1	Operation result is > +127 or < –128

.3 Decimal Adjust Flag (D)

0	Add operation completed
1	Subtraction operation completed

.2 Half-Carry Flag (H)

0	No carry-out of bit 3 or no underflow into bit 3 by addition or subtraction
1	Addition generated carry-out of bit 3 or subtraction generated underflow into bit 3

.1 Fast Interrupt Status Flag (FIS)

0	Interrupt return (IRET) in progress (when read)
1	Fast interrupt service routine in progress (when read)

.0 Bank Address Selection Flag (BA)

0	Bank 0 is selected
1	Bank 1 is selected

IMR — Interrupt Mask Register DDH Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 Interrupt Level 7 (IRQ7) Enable Bit; Key Strobe Interrupt

0	Disable (mask)
1	Enable (un-mask)

.6 Interrupt Level 6 (IRQ6) Enable Bit; AD Interrupt

0	Disable (mask)
1	Enable (un-mask)

.5 Interrupt Level 5 (IRQ5) Enable Bit; Watch Timer Overflow

0	Disable (mask)
1	Enable (un-mask)

.4 Interrupt Level 4 (IRQ4) Enable Bit; External Interrupts P0.4-P0.7

0	Disable (mask)
1	Enable (un-mask)

.3 Interrupt Level 3 (IRQ3) Enable Bit; External Interrupts P0.0-P0.3

0	Disable (mask)
1	Enable (un-mask)

.2 Interrupt Level 2 (IRQ2) Enable Bit; Timer 1 Match/Capture or Overflow

0	Disable (mask)
1	Enable (un-mask)

.1 Interrupt Level 1 (IRQ1) Enable Bit; Timer B Underflow

0	Disable (mask)
1	Enable (un-mask)

.0 Interrupt Level 0 (IRQ0) Enable Bit; Timer A Match/Capture or Overflow

0	Disable (mask)
1	Enable (un-mask)

NOTE: When an interrupt level is masked, any interrupt requests that may be issued are not recognized by the CPU.

IPH — Instruction Pointer (High Byte) DAH Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0 Instruction Pointer Address (High Byte)

The high-byte instruction pointer value is the upper eight bits of the 16-bit instruction pointer address (IP15–IP8). The lower byte of the IP address is located in the IPL register (DBH).

IPL — Instruction Pointer (Low Byte) DBH Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0 Instruction Pointer Address (Low Byte)

The low-byte instruction pointer value is the lower eight bits of the 16-bit instruction pointer address (IP7–IP0). The upper byte of the IP address is located in the IPH register (DAH).

IPR — Interrupt Priority Register FFH Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7, .4, and .1 Priority Control Bits for Interrupt Groups A, B, and C

0	0	0	Group priority undefined
0	0	1	B > C > A
0	1	0	A > B > C
0	1	1	B > A > C
1	0	0	C > A > B
1	0	1	C > B > A
1	1	0	A > C > B
1	1	1	Group priority undefined

.6 Interrupt Subgroup C Priority Control Bit

0	IRQ6 > IRQ7
1	IRQ7 > IRQ6

.5 Interrupt Group C Priority Control Bit

0	IRQ5 > (IRQ6, IRQ7)
1	(IRQ6, IRQ7) > IRQ5

.3 Interrupt Subgroup B Priority Control Bit

0	IRQ3 > IRQ4
1	IRQ4 > IRQ3

.2 Interrupt Group B Priority Control Bit

0	IRQ2 > (IRQ3, IRQ4)
1	(IRQ3, IRQ4) > IRQ2

.0 Interrupt Group A Priority Control Bit

0	IRQ0 > IRQ1
1	IRQ1 > IRQ0

IRQ — Interrupt Request Register DCH Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R	R	R	R	R	R	R	R
Addressing Mode	Register addressing mode only							

.7 Level 7 (IRQ7) Request Pending Bit; Key Strobe Interrupt

0	Not pending
1	Pending

.6 Level 6 (IRQ6) Request Pending Bit; AD Interrupt

0	Not pending
1	Pending

.5 Level 5 (IRQ5) Request Pending Bit; Watch Timer Overflow

0	Not pending
1	Pending

.4 Level 4 (IRQ4) Request Pending Bit; P0.4-P0.7 External Interrupts

0	Not pending
1	Pending

.3 Level 3 (IRQ3) Request Pending Bit; P0.0-P0.3 External Interrupts

0	Not pending
1	Pending

.2 Level 2 (IRQ2) Request Pending Bit; Timer 1 Match/Capture or Overflow

0	Not pending
1	Pending

.1 Level 1 (IRQ1) Request Pending Bit; Timer B Underflow

0	Not pending
1	Pending

.0 Level 0 (IRQ0) Request Pending Bit; Timer A Match/Capture or Overflow

0	Not pending
1	Pending

KSCON — Key Strobe Control Register EBH Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	–	–	0	0	0	0	0
Read/Write	R/W	–	–	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 Key Strobe Enable/Disable Selection Bit

0	Key Strobe output disable
1	Key Strobe output enable

.6-.5

Not used for the S3C8238/C8235/F8235

.4 Strobe Duration Selection Bit

0	45 µsec (1.5 clock)
1	61 µsec (2.0 clock)

.3-.2 Strobe Interval Selection Bits

0	0	1 msec (32 clock)
0	1	2 msec (64 clock)
1	0	3 msec (96 clock)
1	1	4 msec (128 clock)

.1-.0 Key Strobe Output Port Selection Bits

0	0	P4.0-P4.3
0	1	P2.4-P2.7 and P4.0-P4.3
1	x	P2.0-P2.7 and P4.0-P4.3

NOTE: 'x' means don't care.

LCON — LCD Control Register D0H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	–	0	0	0	0
Read/Write	R/W	R/W	R/W	–	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.5 Booster Reference Voltage Selection Bits

0	0	0	0.90 V
0	0	1	0.95 V
0	1	0	1.00 V
0	1	1	1.05 V
1	0	0	1.10 V
1	0	1	1.15 V
1	1	0	1.20 V
1	1	1	1.25 V

.4

Not used for the S3C8238/C8235/F8235

.3-.2 LCD Dot On/Off Control Bits

0	0	Off signal
0	1	On signal
1	x	Normal display

.1-.0 LCD Bias Voltage Selection Bits

0	0	Internal CAP bias; display off (Low signal output through COM/SEG)
0	1	Internal CAP bias; display on (Valid signal output through COM/SEG)
1	x	External register bias; booster off; display on (Valid signal output though COM/SEG)

LMOD — LCD Mode Control Register D1H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 LCD SEG20-23 Output Enable/Disable Selection Bit

0	Output disable
1	Output enable

.6 LCD SEG16-19 Output Enable/Disable Selection Bit

0	Output disable
1	Output enable

.5 LCD SEG12-15 Output Enable/Disable Selection Bit

0	Output disable
1	Output enable

.4 LCD SEG4-7 Output Enable/Disable Selection Bit

0	Output disable
1	Output enable

.3-.2 LCD Clock Signal (LCDCK) Selection Bits

0	0	$fw/2^7$
0	1	$fw/2^6$
1	0	$fw/2^5$
1	1	$fw/2^4$

.1-.0 Duty and Bias Selection Bits

0	0	1/8 duty, 1/4 bias
0	1	1/4 duty, 1/3 bias
1	x	Static

OSCCON — Oscillator Control Register F3H Set 1,Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	–	–	–	–	R/W	R/W	–	R/W
Addressing Mode	Register addressing mode only							

.7-.4

Not used for the S3C8238/C8235/F8235

.3 **Main Sytem Oscillator Control Bit**

0	Main System Oscillator RUN
1	Main System Oscillator STOP

.2 **Sub System Oscillator Control Bit**

0	Sub system oscillator RUN
1	Sub system oscillator STOP

.1

Not used for the S3C8238/C8235/F8235

.0 **System Clock Selection Bit**

0	Main oscillator select
1	Subsystem oscillator select

P0CONH — Port 0 Control Register (High Byte) E0H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.6 P0.7/T1CAP/INT7

0	0	Input mode; (both edge interrupt or T1CAP input - rising start)
0	1	Input mode, pull-up; (falling edge interrupt)
1	0	Push-pull output
1	1	Input mode (T1CAP input - falling start)

.5–.4 P0.6/T1CK/INT6

0	0	Input mode; (both edge interrupt or T1CK input)
0	1	Input mode, pull-up; (falling edge interrup or T1CK input)
1	0	Push-pull output
1	1	Push-pull output

.3–.2 P0.5/T1OUT/INT5

0	0	Input mode; (both edge interrupt)
0	1	Input mode, pull-up; (falling edge interrupt)
1	0	Push-pull output
1	1	Alternative function; T1OUT

.1–.0 P0.4/TBPWM/INT4

0	0	Input mode; (both edge interrupt)
0	1	Input mode, pull-up; (falling edge interrupt)
1	0	Push-pull output
1	1	Alternative function; TBPWM

P0CONL — Port 0 Control Register (Low Byte) E1H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.6 **P0.3/INT3**

0	0	Input mode; interrupt on rising edge
0	1	Input mode, pull-up; interrupt on falling edge
1	0	Input mode; interrupt on both edge
1	1	Push-pull output

.5–.4 **P0.2/INT2**

0	0	Input mode; interrupt on rising edge
0	1	Input mode, pull-up; interrupt on falling edge
1	0	Input mode; interrupt on both edge
1	1	Push-pull output

.3–.2 **P0.1/INT1**

0	0	Input mode; interrupt on rising edge
0	1	Input mode, pull-up; interrupt on falling edge
1	0	Input mode; interrupt on both edge
1	1	Push-pull output

.1–.0 **P0.0/INT0**

0	0	Input mode; interrupt on rising edge
0	1	Input mode, pull-up; interrupt on falling edge
1	0	Input mode; interrupt on both edge
1	1	Push-pull output

P0INT — Port 0 Interrupt Control Register E5H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 P0.7 External Interrupt (INT7) Enable Bit

0	Disable interrupt
1	Enable interrupt

.6 P0.6 External Interrupt (INT6) Enable Bit

0	Disable interrupt
1	Enable interrupt

.5 P0.5 External Interrupt (INT5) Enable Bit

0	Disable interrupt
1	Enable interrupt

.4 P0.4 External Interrupt (INT4) Enable Bit

0	Disable interrupt
1	Enable interrupt

.3 P0.3 External Interrupt (INT3) Enable Bit

0	Disable interrupt
1	Enable interrupt

.2 P0.2 External Interrupt (INT2) Enable Bit

0	Disable interrupt
1	Enable interrupt

.1 P0.1 External Interrupt (INT1) Enable Bit

0	Disable interrupt
1	Enable interrupt

.0 P0.0 External Interrupt (INT0) Enable Bit

0	Disable interrupt
1	Enable interrupt

P0PND — Port 0 Interrupt Pending Register E6H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 P0.7/PND7 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.6 P0.6/PND6 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.5 P0.5/PND5 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.4 P0.4/PND4 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.3 P0.3/PND3 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.2 P0.2/PND2 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.1 P0.1/PND1 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.0 P0.0/PND0 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

P1CONH — Port 1 Control Register (High Byte) E4H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.6 P1.7/PG3/AD7/COM4

0	0	Input mode
0	1	AD7 converter input; Normal input off
1	0	Push-pull output (COM4 output enable)
1	1	Alternative function; PG3 output

.5-.4 P1.6/PG2/AD6/COM5

0	0	Input mode
0	1	AD6 converter input; Normal input off
1	0	Push-pull output (COM5 output enable)
1	1	Alternative function; PG2 output

.3-.2 P1.5/PG1/AD5/COM6

0	0	Input mode
0	1	AD5 converter input; Normal input off
1	0	Push-pull output (COM6 output enable)
1	1	Alternative function; PG1 output

.1-.0 P1.4/PG0/AD4/COM7

0	0	Input mode
0	1	AD4 converter input; Normal input off
1	0	Push-pull output (COM7 output enable)
1	1	Alternative function; PG0 output

NOTE: When users use Port 1, users must be care of the pull-up resistance status.

P1CONL — Port 1 Control Register (Low Byte) E5H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.6 **P1.3/AD3**

0	0	Input mode
0	1	AD3 input; Normal input off
1	0	Push-pull output
1	1	Open-drain output

.5-.4 **P1.2/AD2**

0	0	Input mode
0	1	AD2 input; Normal input off
1	0	Push-pull output
1	1	Open-drain output

.3-.2 **P1.1/AD1**

0	0	Input mode
0	1	AD1 input; Normal input off
1	0	Push-pull output
1	1	Open-drain output

.1-.0 **P1.0/AD0**

0	0	Input mode
0	1	AD0 input; Normal input off
1	0	Push-pull output
1	1	Open-drain output

NOTE: When users use Port 1, users must be care of the pull-up resistance status.

P1PUR — Port 1 Pull-up Control Register E3H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 P1.7 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

.6 P1.6 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

.5 P1.5 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

.4 P1.4 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

.3 P1.3 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

.2 P1.2 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

.1 P1.1 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

.0 P1.0 Pull-up Resistor Enable Bit

0	Pull-up disable
1	Pull-up enable

NOTE: You can enable Port 1 pull-up resistor, when Port 1, is configured only as input mode or open-drain output mode.

P2CONH — Port 2 Control Register (High Byte) E6H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.6 P2.7/SEG19/KSTR8

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG19/Key strobe, KSTR8 output enable)
1	1	Open-drain output (SEG19/Key strobe, KSTR8 output enable)

.5-.4 P2.6/SEG18/KSTR7

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG18/Key strobe, KSTR7 output enable)
1	1	Open-drain output (SEG18/Key strobe, KSTR7 output enable)

.3–.2 P2.5/ SEG17/KSTR6

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG17/Key strobe, KSTR6 output enable)
1	1	Open-drain output (SEG17/Key strobe, KSTR6 output enable)

.1–.0 P2.4/ SEG16/KSTR5

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG16/Key strobe, KSTR5 output enable)
1	1	Open-drain output (SEG16/Key strobe, KSTR5 output enable)

P2CONL — Port 2 Control Register (Low Byte) E7H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.6 P2.3/SEG15/KSTR4

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG15/Key strobe, KSTR4 output enable)
1	1	Open-drain output (SEG15/Key strobe, KSTR4 output enable)

.5-.4 P2.2/SEG14/KSTR3

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG14/Key strobe, KSTR3 output enable)
1	1	Open-drain output (SEG14/Key strobe, KSTR3 output enable)

.3-.2 P2.1/SEG13/KSTR2

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG13/Key strobe, KSTR2 output enable)
1	1	Open-drain output (SEG13/Key strobe, KSTR2 output enable)

.1-.0 P2.0/SEG12/KSTR1

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG12/Key strobe, KSTR1 output enable)
1	1	Open-drain output (SEG12/Key strobe, KSTR1 output enable)

P3CON — Port 3 Control Register E8H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.6 P3.3/BUZ/KIN3

0	0	Inputmode; External Interrupt
0	1	Watch timer; Buzzer output
1	0	Push-pull output
1	1	Alternative mode; KIN3 input; Only falling edge interrupt (When key strobe output is enable (KSCON.7 = 1), port status is high-impedence during interval and pull-up during strobe out)

.5-.4 P3.2/TACAP/KIN2

0	x	Inputmode; External Interrupt (TACAP input)
1	0	Push-pull output
1	1	Alternative mode; KIN2 (When key strobe output is enable (KSCON.7 = 1), port status is high-impedence during interval and pull-up during strobe out)

.3-.2 P3.1/TACK/KIN1

0	x	Inputmode; External Interrupt (TACAP input)
1	0	Push-pull output
1	1	Alternative mode; KIN1 (When key strobe output is enable (KSCON.7 = 1), port status is high-impedence during interval and pull-up during strobe out)

.1-.0 P3.0/TAPWM/TAOUT/KIN0

0	0	Inputmode; External Interrupt
0	1	TAPWM or TAOUT output
1	0	Push-pull output
1	1	Alternative mode; KIN0 (When key strobe output is enable (KSCON.7 = 1), port status is high-impedence during interval and pull-up during strobe out)

P3INT — Port 3 Interrupt Control Register E7H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.6 P3.3/KIN3 Interrupt Enable/Disable Selection Bits

0	x	Interrupt Disable
1	0	Interrupt Enable; falling edge
1	1	Interrupt Enable; rising edge

.5-.4 P3.2/KIN2 Interrupt Enable/Disable Selection Bits

0	x	Interrupt Disable
1	0	Interrupt Enable; falling edge
1	1	Interrupt Enable; rising edge

.3-.2 P3.1/KIN1 Interrupt Enable/Disable Selection Bits

0	x	Interrupt Disable
1	0	Interrupt Enable; falling edge
1	1	Interrupt Enable; rising edge

.1-.0 P3.0/KIN0 Interrupt Enable/Disable Selection Bits

0	x	Interrupt Disable
1	0	Interrupt Enable; falling edge
1	1	Interrupt Enable; rising edge

NOTE: When you want to use any pin in P3 as alternative mode to get a key-input(KIN0-3), then you have to choose only falling edge interrupt.

P3PND — Port 3 Interrupt Pending Register E8H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	–	–	–	0	0	0	0
Read/Write	–	–	–	–	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.4 Not used for the S3C8238/C8235/F8235

.3 P3.3/KIN3 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.2 P3.2/KIN2 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.1 P3.1/KIN1 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

.0 P3.0/KIN0 Interrupt Pending Bit

0	Interrupt request is not pending, pending bit clear when write 0
1	Interrupt request is pending

NOTE: When you want to use any pin in P3 as alternative mode to get a key-input(KIN0-3), then you have to choose only falling edge interrupt.

P4CON — Port 4 Control Register EAH Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.6 P4.3/SEG23/PG7/KSTR12

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG23/Key strobe, KSTR12 output enable)
1	1	Alternative function; PG7 output

.5-.4 P4.2/SEG22/PG6/KSTR11

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG22/Key strobe, KSTR11 output enable)
1	1	Alternative function; PG6 output

.3-.2 P4.1/SEG21/PG5/KSTR10

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG21/Key strobe, KSTR10 output enable)
1	1	Alternative function; PG5 output

.1-.0 P4.0/SEG20/PG4/KSTR9

0	0	Input mode
0	1	Input mode, pull-up
1	0	Push-pull output (SEG20/Key strobe, KSTR9 output enable)
1	1	Alternative function; PG4 output

PGCON — Pattern Generation Control Register F5H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	–	–	–	0	0	0	0
Read/Write	–	–	–	–	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.4

Not used for the S3C8238/C8235/F8235

.3 S/W Trigger Start Bit

0	No effect
1	S/W trigger start (Auto clear)

.2 PG Operation Disable/Enable Selection Bit

0	PG operation disable
1	PG operation enable

.1-.0 PG Operation Mode Selection Bits

0	0	Timer A match siganal triggering
0	1	Timer B underflow siganal triggering
1	0	Timer 1 match siganal triggering
1	1	S/W triggering mode

PP — Register Page Pointer DFH Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.4 Destination Register Page Selection Bits

0	0	0	0	Destination: page 0
0	0	0	1	Destination: page 1
0	0	1	0	Destination: page 2

.3-.0 Source Register Page Selection Bits

0	0	0	0	Source: page 0
0	0	0	1	Source: page 1
0	0	1	0	Source: page 2

NOTE: In the S3C8238/C8235/F8235 microcontroller, the internal register file is configured as three pages (Pages 0-2). The pages 0-1 are used for general purpose register file, and page 2 is used for LCD data register or general purpose registers.

RP0 — Register Pointer 0 D6H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	1	1	0	0	0	–	–	–
Read/Write	R/W	R/W	R/W	R/W	R/W	–	–	–
Addressing Mode	Register addressing only							

.7-.3 Register Pointer 0 Address Value

Register pointer 0 can independently point to one of the 256-byte working register areas in the register file. Using the register pointers RP0 and RP1, you can select two 8-byte register slices at one time as active working register space. After a reset, RP0 points to address C0H in register set 1, selecting the 8-byte working register slice C0H–C7H.

.2-.0 Not used for the S3C8238/C8235/F8235

RP1 — Register Pointer 1 D7H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	1	1	0	0	1	–	–	–
Read/Write	R/W	R/W	R/W	R/W	R/W	–	–	–
Addressing Mode	Register addressing only							

.7-.3 Register Pointer 1 Address Value

Register pointer 1 can independently point to one of the 256-byte working register areas in the register file. Using the register pointers RP0 and RP1, you can select two 8-byte register slices at one time as active working register space. After a reset, RP1 points to address C8H in register set 1, selecting the 8-byte working register slice C8H–CFH.

.2-.0 Not used for the S3C8238/C8235/F8235

SPH — Stack Pointer (High Byte) D8H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0 Stack Pointer Address (High Byte)

The high-byte stack pointer value is the upper eight bits of the 16-bit stack pointer address (SP15–SP8). The lower byte of the stack pointer value is located in register SPL (D9H). The SP value is undefined following a reset.

SPL — Stack Pointer (Low Byte) D9H Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0 Stack Pointer Address (Low Byte)

The low-byte stack pointer value is the lower eight bits of the 16-bit stack pointer address (SP7–SP0). The upper byte of the stack pointer value is located in register SPH (D8H). The SP value is undefined following a reset.

STPCON — Stop Control Register F4H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0 STOP Control Bits

1 0 1 0 0 1 0 1	Enable stop instruction
Other values	Disable stop instruction

NOTE: Before executing the STOP instruction, You must set this STPCON register as “10100101b”. Otherwise the STOP instruction will not be executed.

SYM — System Mode Register DEH Set 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	–	–	x	x	x	0	0
Read/Write	R/W	–	–	–	–	–	–	R/W
Addressing Mode	Register addressing mode only							

.7 Not used, always logic zero

.6-.1 Not used for the S3C8238/C8235/F8235

.0 **Global Interrupt Enable Bit** (note)

0	Disable global interrupt processing
1	Enable global interrupt processing

NOTE: Following a reset, you must enable global interrupt processing by executing an EI instruction (not by writing a "1" to SYM.0).

T1CON — Timer 1 Control Register F1H Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.5 Timer 1 Input Clock Selection Bits

0	0	0	fxx/1
0	0	1	fxx/8
0	1	0	fxx/64
0	1	1	T1CK
1	0	x	TBUF
1	1	x	Counter Stop

.4-.3 Timer 1 Operating Mode Selection Bits

0	0	Interval mode
0	1	Capture mode (Capture on falling edge, OVF can occur)
1	0	Capture mode (Capture on rising edge, OVF can occur)
1	1	Capture mode (Capture on both edge, OVF can occur)

.2 Timer 1 Counter Enable Bit

0	No effect
1	Clear the timer 1 counter (Auto-clear bit)

.1 Timer 1 Match/Capture Interrupt Enable Bit

0	Disable interrupt
1	Enable interrupt

.0 Timer 1 Overflow Interrupt Enable

0	Disable overflow interrupt
1	Enable overflow interrupt

TACON — Timer A Control Register EAH Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	–
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	–
Addressing Mode	Register addressing mode only							

.7-.6 Timer A Input Clock Selection Bits

0	0	fxx/1024
0	1	fxx/256
1	0	fxx/64
1	1	External clock (TACK)

.5-.4 Timer A Operating Mode Selection Bits

0	0	Internal mode (TAOUT mode)
0	1	Capture mode (capture on rising edge, counter running, OVF can occur)
1	0	Capture mode (capture on falling edge, counter running, OVF can occur)
1	1	PWM mode (OVF interrupt can occur)

.3 Timer A Counter Clear Bit

0	No effect
1	Clear the timer A counter (After clearing, return to zero)

.2 Timer A Overflow Interrupt Enable Bit

0	Disable overflow interrupt
1	Enable overflow interrupt

.1 Timer A Match/Capture Interrupt Enable Bit

0	Disable interrupt
1	Enable interrupt

.0 Not used for the S3C8238/C8235/F8235

TBCON — Timer B Control Register EDH Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.6 Timer B Input Clock Selection Bits

0	0	fxx
0	1	fxx/2
1	0	fxx/4
1	1	fxx/8

.5–.4 Timer B Interrupt Time Selection Bits

0	0	Elapsed time for low data value
0	1	Elapsed time for high data value
1	0	Elapsed time for low and high data values
1	1	Invalid setting

.3 Timer B Interrupt Enable Bit

0	Disable Interrupt
1	Enable Interrupt

.2 Timer B Start/Stop Bit

0	Stop timer B
1	Start timer B

.1 Timer B Mode Selection Bit

0	One-shot mode
1	Repeating mode

.0 Timer B Output flip-flop Control Bit

0	T-FF is low
1	T-FF is high

NOTE: fxx is selected clock for system.

TINTPND — Timer A,1 Interrupt Pending Register E9H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	–	–	–	0	0	0	0
Read/Write	–	–	–	–	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.4 Not used for the S3C8238/C8235/F8235

.3 Timer 1 Overflow Interrupt Pending Bit

0	No interrupt pending
0	*Clear pending bit when write*
1	Interrupt pending

.2 Timer 1 Match/Capture Interrupt Pending Bit

0	No interrupt pending
0	*Clear pending bit when write*
1	Interrupt pending

.1 Timer A Overflow Interrupt Pending Bit

0	No interrupt pending
0	*Clear pending bit when write*
1	Interrupt pending

.0 Timer A Match/Capture Interrupt Pending Bit

0	No interrupt pending
0	*Clear pending bit when write*
1	Interrupt pending

VLDCON — Voltage Level Detector Control Register F1H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	–	–	–	R/W	R	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7-.4

Not used for the S3C8238/C8235/F8235

.3 VLD Level Set Bit

0	V_{DD} is higher than reference voltage
1	V_{DD} is lower than reference voltage

.2 VLD Operation Enable Bit

0	Operation off
1	Operation on

.1-.0 Reference Voltage Selection Bits

0	0	V_{VLD} = 2.4 V
0	1	V_{VLD} = 2.7 V
1	0	V_{VLD} = 3.3 V
1	1	V_{VLD} = 4.5 V

WTCON — Watch Timer Control Register F2H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 Watch Timer Clock Selection Bit

0	Main system clock divided by 2^7 (fxx/128)
1	Sub system clock (fxt)

.6 Watch Timer Interrupt Enable Bit

0	Disable watch timer interrupt
1	Enable watch timer interrupt

.5–.4 Buzzer Signal Selection Bits

0	0	0.5 kHz buzzer (BUZ) signal output
0	1	1 kHz buzzer (BUZ) signal output
1	0	2 kHz buzzer (BUZ) signal output
1	1	4 kHz buzzer (BUZ) signal output

.3–.2 Watch Timer Speed Selection Bits

0	0	1.0 s Interval
0	1	0.5 s Interval
1	0	0.25 s Interval
1	1	3.91 ms Interval

.1 Watch Timer Enable Bit

0	Disable watch timer; Clear frequency dividing circuits
1	Enable watch timer

.0 Watch Timer Interrupt Pending Bit

0	Interrupt is not pending, Clear pending bit when write
1	Interrupt is pending

5 INTERRUPT STRUCTURE

OVERVIEW

The S3C8-series interrupt structure has three basic components: levels, vectors, and sources. The SAM8 CPU recognizes up to eight interrupt levels and supports up to 128 interrupt vectors. When a specific interrupt level has more than one vector address, the vector priorities are established in hardware. A vector address can be assigned to one or more sources.

Levels

Interrupt levels are the main unit for interrupt priority assignment and recognition. All peripherals and I/O blocks can issue interrupt requests. In other words, peripheral and I/O operations are interrupt-driven. There are eight possible interrupt levels: IRQ0–IRQ7, also called level 0–level 7. Each interrupt level directly corresponds to an interrupt request number (IRQn). The total number of interrupt levels used in the interrupt structure varies from device to device. The S3C8238/C8235/F8235 interrupt structure recognizes eight interrupt levels.

The interrupt level numbers 0 through 7 do not necessarily indicate the relative priority of the levels. They are just identifiers for the interrupt levels that are recognized by the CPU. The relative priority of different interrupt levels is determined by settings in the interrupt priority register, IPR. Interrupt group and subgroup logic controlled by IPR settings lets you define more complex priority relationships between different levels.

Vectors

Each interrupt level can have one or more interrupt vectors, or it may have no vector address assigned at all. The maximum number of vectors that can be supported for a given level is 128 (The actual number of vectors used for S3C8-series devices is always much smaller). If an interrupt level has more than one vector address, the vector priorities are set in hardware. S3C8238/C8235/F8235 uses sixteen vectors.

Sources

A source is any peripheral that generates an interrupt. A source can be an external pin or a counter overflow. Each vector can have several interrupt sources. In the S3C8238/C8235/F8235 interrupt structure, there are sixteen possible interrupt sources.

When a service routine starts, the respective pending bit should be either cleared automatically by hardware or cleared "manually" by program software. The characteristics of the source's pending mechanism determine which method would be used to clear its respective pending bit.

INTERRUPT TYPES

The three components of the S3C8 interrupt structure described before — levels, vectors, and sources — are combined to determine the interrupt structure of an individual device and to make full use of its available interrupt logic. There are three possible combinations of interrupt structure components, called interrupt types 1, 2, and 3. The types differ in the number of vectors and interrupt sources assigned to each level (see Figure 5-1):

Type 1: One level (IRQn) + one vector (V_1) + one source (S_1)

Type 2: One level (IRQn) + one vector (V_1) + multiple sources ($S_1 – S_n$)

Type 3: One level (IRQn) + multiple vectors ($V_1 – V_n$) + multiple sources ($S_1 – S_n$, $S_{n+1} – S_{n+m}$)

In the S3C8238/C8235/F8235 microcontroller, two interrupt types are implemented.

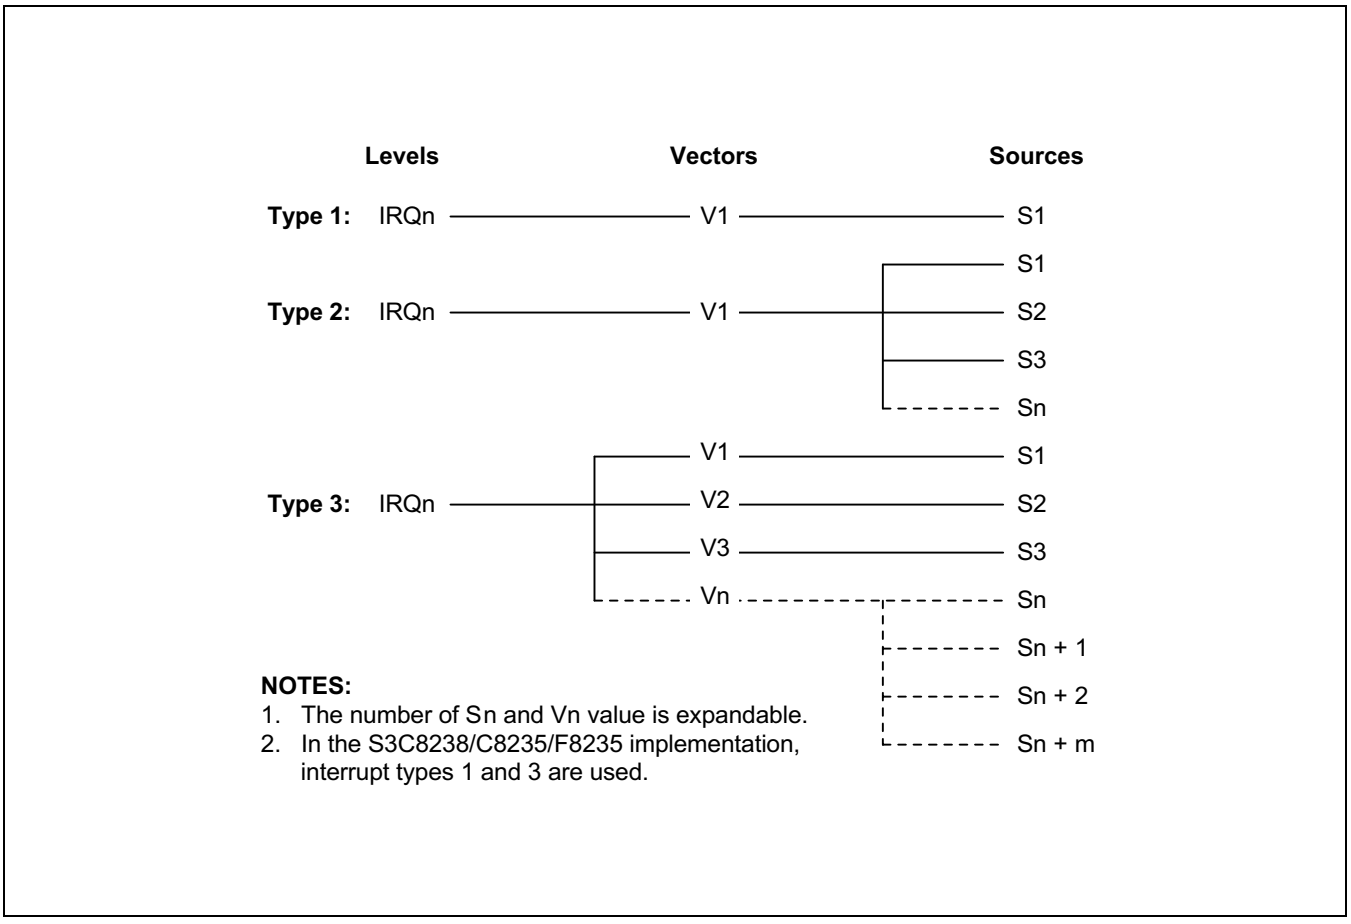

Figure 5-1. S3C8-Series Interrupt Types

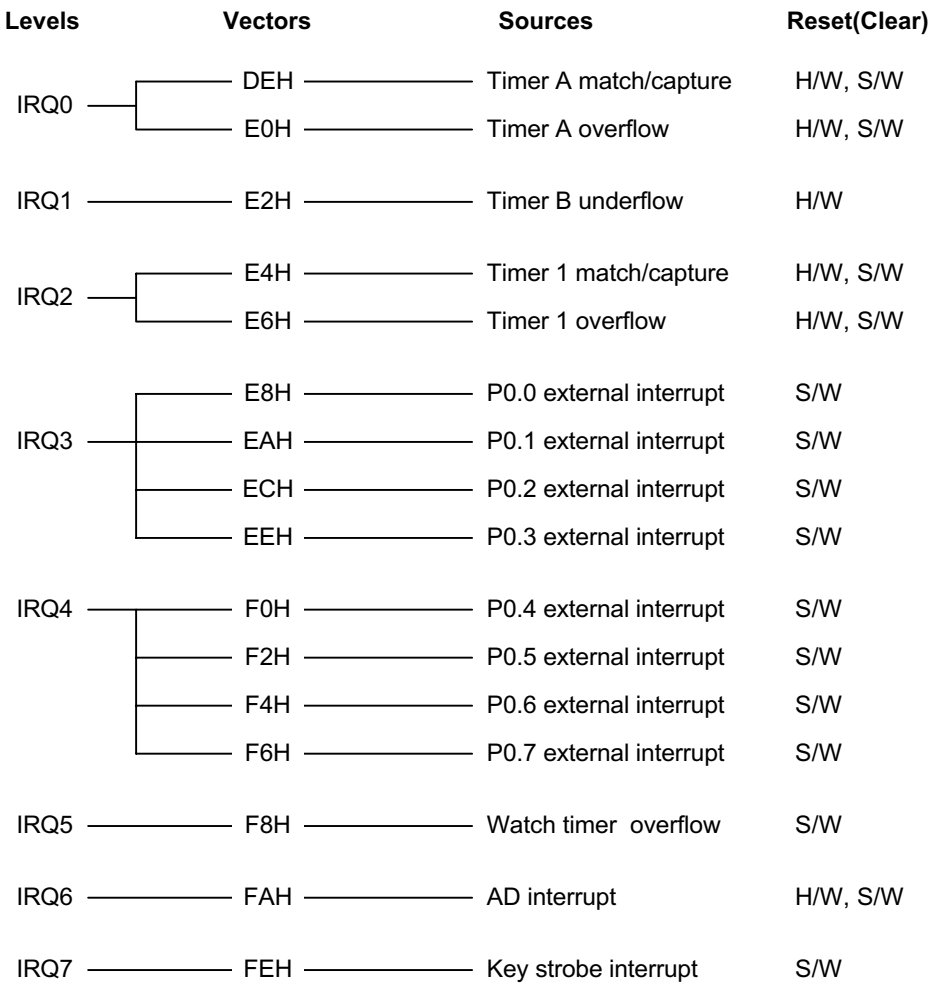
S3C8238/C8235/F8235 INTERRUPT STRUCTURE

The S3C8238/C8235/F8235 microcontroller supports sixteen interrupt sources. All sixteen of the interrupt sources have a corresponding interrupt vector address. Eight interrupt levels are recognized by the CPU in this device-specific interrupt structure, as shown in Figure 5-2.

When multiple interrupt levels are active, the interrupt priority register (IPR) determines the order in which contending interrupts are to be serviced. If multiple interrupts occur within the same interrupt level, the interrupt with the lowest vector address is usually processed first (The relative priorities of multiple interrupts within a single level are fixed in hardware).

When the CPU grants an interrupt request, interrupt processing starts. All other interrupts are disabled and the program counter value and status flags are pushed to stack. The starting address of the service routine is fetched from the appropriate vector address (plus the next 8-bit value to concatenate the full 16-bit address) and the service routine is executed.



NOTES:

1. Within a given interrupt level, the lower vector address has high priority. For example, DEH has higher priority than E0H within the level IRQ0 the priorities within each level are set at the factory.
2. External interrupts are triggered by a rising or falling edge, depending on the corresponding control register setting.

Figure 5-2. S3C8238/C8235/F8235 Interrupt Structure

INTERRUPT VECTOR ADDRESSES

All interrupt vector addresses for the S3C8238/C8235/F8235 interrupt structure are stored in the vector address area of the internal 32-Kbyte ROM, 0H–7FFFH (see Figure 5-3).

You can allocate unused locations in the vector address area as normal program memory. If you do so, please be careful not to overwrite any of the stored vector addresses (Table 5-1 lists all vector addresses).

The program reset address in the ROM is 0100H.

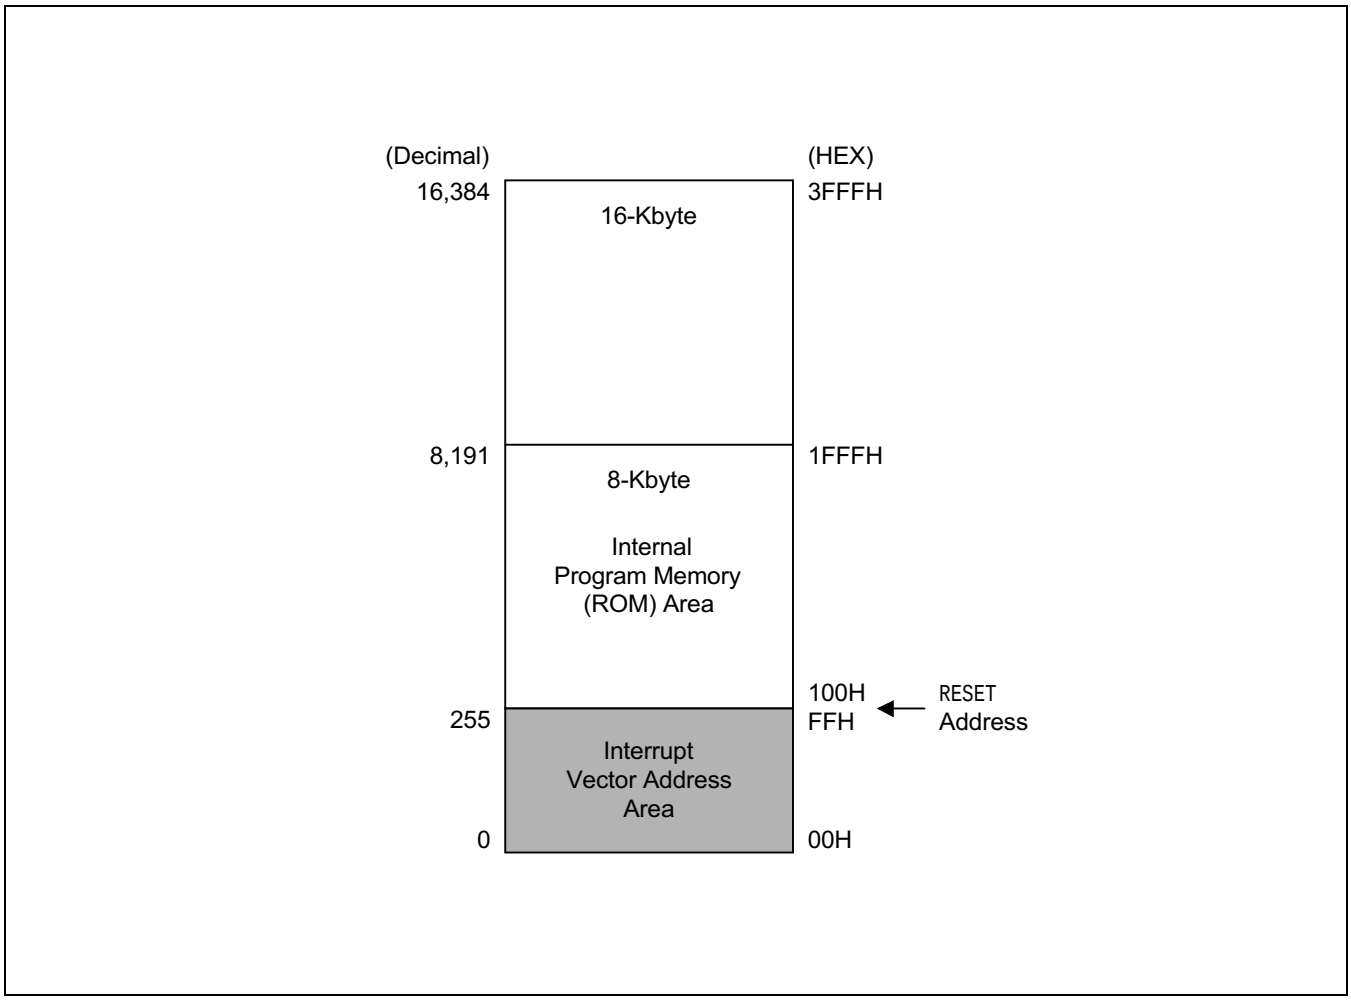


Figure 5-3. ROM Vector Address Area

Table 5-1. Interrupt Vectors

Vector Address		Interrupt Source	Request		Reset/Clear	
Decimal Value	Hex Value		Interrupt Level	Priority in Level	H/W	S/W
254	FEH	Key strobe interrupt	IRQ7	–		√
250	FAH	AD Interrupt	IRQ6	–	√	√
248	F8H	Watch tiner overflow	IRQ5	–		√
246	F6H	P0.7 external interrupt	IRQ4	3		√
244	F4H	P0.6 external interrupt		2		√
242	F2H	P0.5 external interrupt		1		√
240	F0H	P0.4 external interrupt		0		√
238	EEH	P0.3 external interrupt	IRQ3	3		√
236	ECH	P0.2 external interrupt		2		√
234	EAH	P0.1 external interrupt		1		√
232	E8H	P0.0 external interrupt		0		√
230	E6H	Timer 1 overflow	IRQ2	1	√	√
228	E4H	Timer 1 match/capture		0	√	√
226	E2H	Timer B underflow	IRQ1	–	√	
220	E0H	Timer A overflow	IRQ0	1	√	√
218	DEH	Timer A match/capture		0	√	√

NOTES:

1. Interrupt priorities are identified in inverse order: "0" is the highest priority, "1" is the next highest, and so on.
2. If two or more interrupts within the same level contend, the interrupt with the lowest vector address usually has priority over one with a higher vector address. The priorities within a given level are fixed in hardware.

ENABLE/DISABLE INTERRUPT INSTRUCTIONS (EI, DI)

Executing the Enable Interrupts (EI) instruction globally enables the interrupt structure. All interrupts are then serviced as they occur according to the established priorities.

NOTE

The system initialization routine executed after a reset must always contain an EI instruction to globally enable the interrupt structure.

During the normal operation, you can execute the DI (Disable Interrupt) instruction at any time to globally disable interrupt processing. The EI and DI instructions change the value of bit 0 in the SYM register.

SYSTEM-LEVEL INTERRUPT CONTROL REGISTERS

In addition to the control registers for specific interrupt sources, four system-level registers control interrupt processing:

— The interrupt mask register, IMR, enables (un-masks) or disables (masks) interrupt levels.

— The interrupt priority register, IPR, controls the relative priorities of interrupt levels.

— The interrupt request register, IRQ, contains interrupt pending flags for each interrupt level (as opposed to each interrupt source).

— The system mode register, SYM, enables or disables global interrupt processing (SYM settings also enable fast interrupts and control the activity of external interface, if implemented).

Table 5-2. Interrupt Control Register Overview

Control Register	ID	R/W	Function Description
Interrupt mask register	IMR	R/W	Bit settings in the IMR register enable or disable interrupt processing for each of the eight interrupt levels: IRQ0–IRQ7.
Interrupt priority register	IPR	R/W	Controls the relative processing priorities of the interrupt levels. The seven levels of S3C8238/C8235/F8235 are organized into three groups: A, B, and C. Group A is IRQ0 and IRQ1, group B is IRQ2, IRQ3 and IRQ4, and group C is IRQ5, IRQ6, and IRQ7.
Interrupt request register	IRQ	R	This register contains a request pending bit for each interrupt level.
System mode register	SYM	R/W	This register enables/disables fast interrupt processing, dynamic global interrupt processing, and external interface control (An external memory interface is implemented in the S3C8238/C8235/F8235 microcontroller).

NOTE: Before IMR register is changed to any value, all interrupts must be disable.
Using DI instruction is recommended.

INTERRUPT PROCESSING CONTROL POINTS

Interrupt processing can therefore be controlled in two ways: globally or by specific interrupt level and source. The system-level control points in the interrupt structure are:

— Global interrupt enable and disable (by EI and DI instructions or by direct manipulation of SYM.0)

— Interrupt level enable/disable settings (IMR register)

— Interrupt level priority settings (IPR register)

— Interrupt source enable/disable settings in the corresponding peripheral control registers

NOTE

When writing an application program that handles interrupt processing, be sure to include the necessary register file address (register pointer) information.

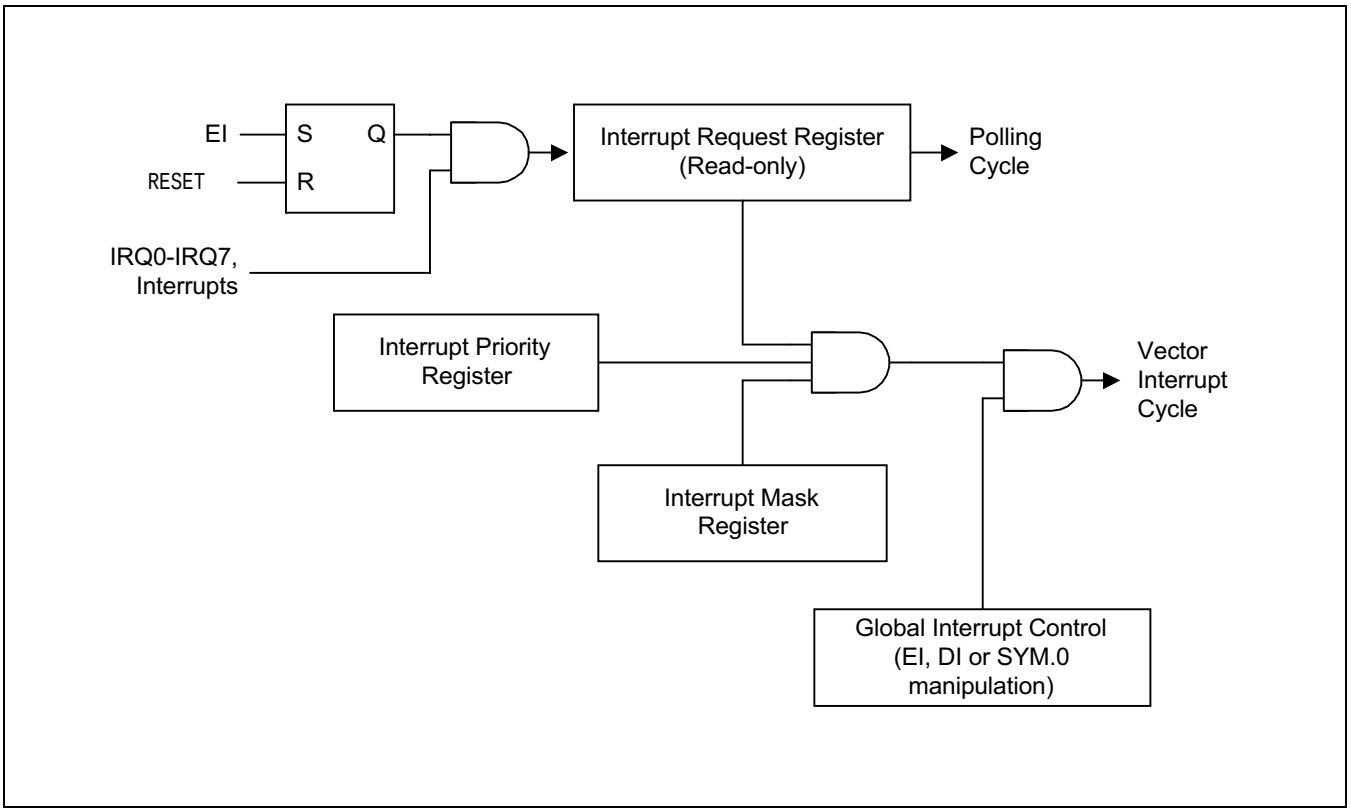

Figure 5-4. Interrupt Function Diagram

PERIPHERAL INTERRUPT CONTROL REGISTERS

For each interrupt source there is one or more corresponding peripheral control registers that let you control the interrupt generated by the related peripheral (see Table 5-3).

Table 5-3. Interrupt Source Control and Data Registers

Interrupt Source	Interrupt Level	Register(s)	Location(s) in Set 1
Timer A overflow	IRQ0	TINTPND	E9H, bank 0
Timer A match/capture		TACON	EAH, bank 0
		TACNT	EBH, bank 0
		TADATA	ECH, bank 0
Timer B underflow	IRQ1	TBCON	EDH, bank 0
		TBDATAH, TBDATAL	EEH, EFH, bank 0
Timer 1 overflow	IRQ2	TINTPND	E9H, bank 0
Timer 1 match/capture		T1CON	F1H, bank 1
		T1CNTH	F2H, bank 1
		T1CNTL	F3H, bank 1
		T1DATA1H	F4H, bank 1
		T1DATA1L	F5H, bank 1
		T1DATA2H	F6H, bank 1
		T1DATA2L	F7H, bank 1
		T1PS	F8H, bank 1
P0.3 external interrupt	IRQ3	P0CONL	E1H, bank 1
P0.2 external interrupt		P0INT	E5H, bank 0
P0.1 external interrupt		P0PND	E6H, bank 0
P0.0 external interrupt			
P0.7 external interrupt	IRQ4	P0CONH	E0H, bank 1
P0.6 external interrupt		P0INT	E5H, bank 0
P0.5 external interrupt		P0PND	E6H, bank 0
P0.4 external interrupt			
Watch timer overflow	IRQ5	WTCON	F2H, bank 0
AD Interrupt	IRQ6	ADCON	F7H, bank 0
		ADDATAH	F8H, bank 0
		ADDATAL	F9H, bank 0
		ADINT	FAH, bank 0
		P1CONH	E4H, bank 1
		P1CONL	E5H, bank 1
Key strobe interrupt	IRQ7	KSCON	EBH, bank 1
		KSDATA	F0H, bank 0

SYSTEM MODE REGISTER (SYM)

The system mode register, SYM (set 1, DEH), is used to globally enable and disable interrupt processing (see Figure 5-5).

A reset clears SYM.0 to "0".

The instructions EI and DI enable and disable global interrupt processing, respectively, by modifying the bit 0 value of the SYM register. In order to enable interrupt processing an Enable Interrupt (EI) instruction must be included in the initialization routine, which follows a reset operation. Although you can manipulate SYM.0 directly to enable and disable interrupts during the normal operation, it is recommended to use the EI and DI instructions for this purpose.

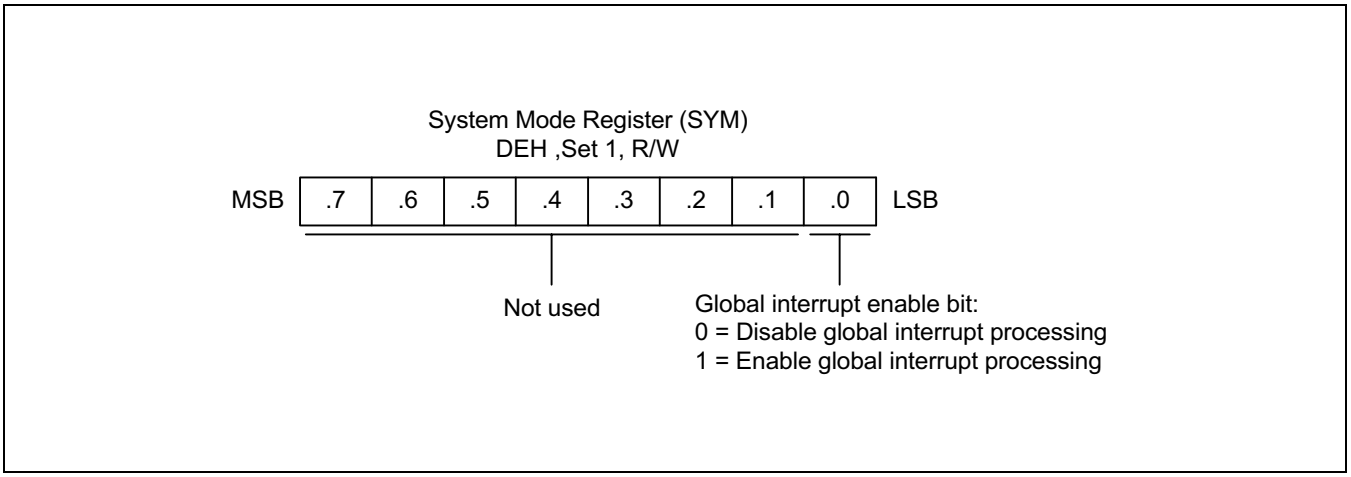

Figure 5-5. System Mode Register (SYM)

INTERRUPT MASK REGISTER (IMR)

The interrupt mask register, IMR (set 1, DDH) is used to enable or disable interrupt processing for individual interrupt levels. After a reset, all IMR bit values are undetermined and must therefore be written to their required settings by the initialization routine.

Each IMR bit corresponds to a specific interrupt level: bit 1 to IRQ1, bit 2 to IRQ2, and so on. When the IMR bit of an interrupt level is cleared to "0", interrupt processing for that level is disabled (masked). When you set a level's IMR bit to "1", interrupt processing for the level is enabled (not masked).

The IMR register is mapped to register location DDH in set 1. Bit values can be read and written by instructions using the Register addressing mode.

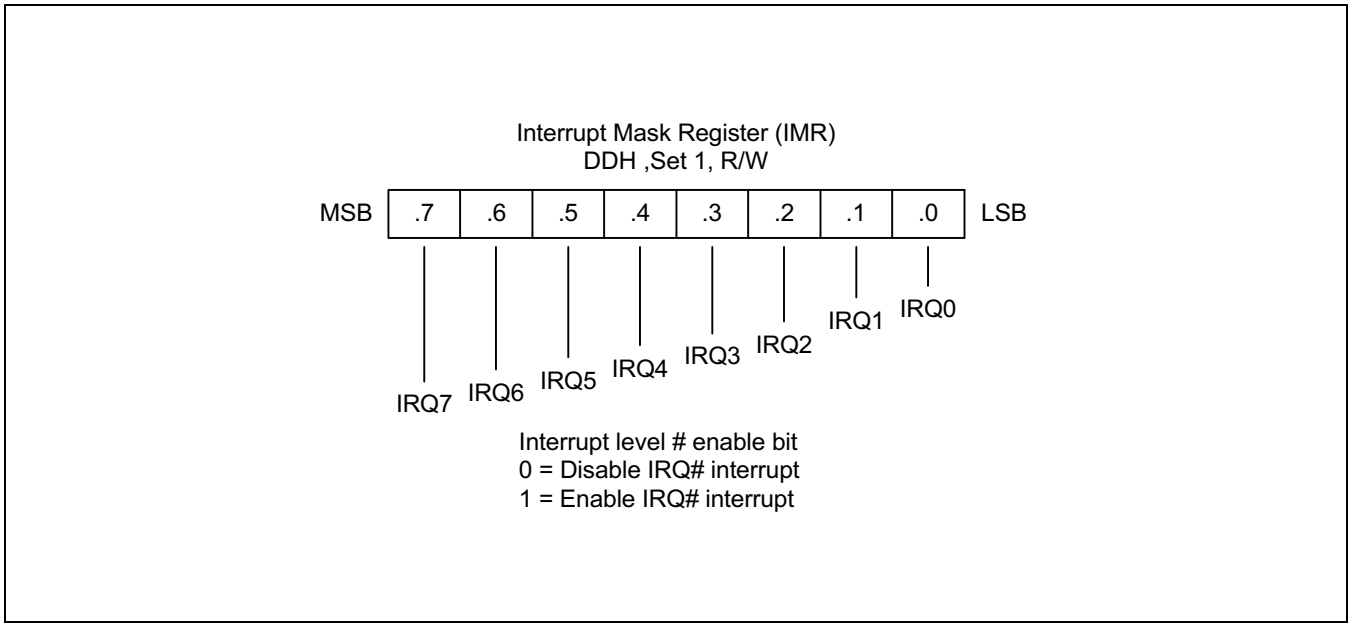

Figure 5-6. Interrupt Mask Register (IMR)

INTERRUPT PRIORITY REGISTER (IPR)

The interrupt priority register, IPR (set 1, bank 0, FFH), is used to set the relative priorities of the interrupt levels in the microcontroller's interrupt structure. After a reset, all IPR bit values are undetermined and must therefore be written to their required settings by the initialization routine.

When more than one interrupt sources are active, the source with the highest priority level is serviced first. If two sources belong to the same interrupt level, the source with the lower vector address usually has the priority (This priority is fixed in hardware).

To support programming of the relative interrupt level priorities, they are organized into groups and subgroups by the interrupt logic. Please note that these groups (and subgroups) are used only by IPR logic for the IPR register priority definitions (see Figure 5-7):

Group A IRQ0, IRQ1

Group B IRQ2, IRQ3, IRQ3

Group C IRQ5, IRQ6, IRQ7

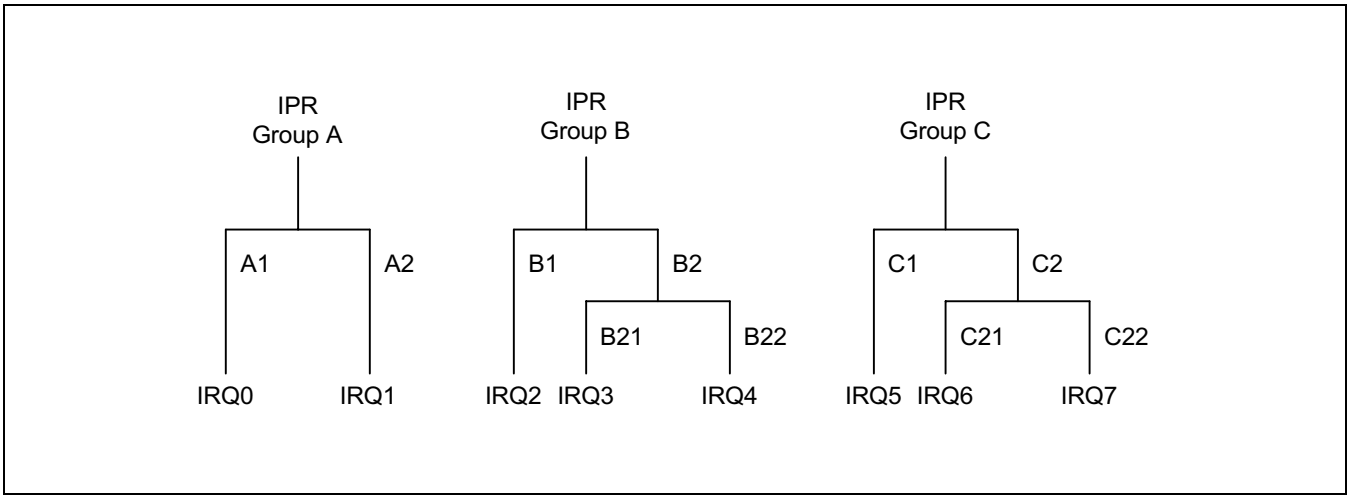

Figure 5-7. Interrupt Request Priority Groups

As you can see in Figure 5-8, IPR.7, IPR.4, and IPR.1 control the relative priority of interrupt groups A, B, and C. For example, the setting "001B" for these bits would select the group relationship B > C > A. The setting "101B" would select the relationship C > B > A.

The functions of the other IPR bit settings are as follows:

— IPR.5 controls the relative priorities of group C interrupts.

— Interrupt group C includes a subgroup that has an additional priority relationship among the interrupt levels 5, 6, and 7. IPR.6 defines the subgroup C relationship. IPR.5 controls the interrupt group C.

— IPR.0 controls the relative priority setting of IRQ0 and IRQ1 interrupts.

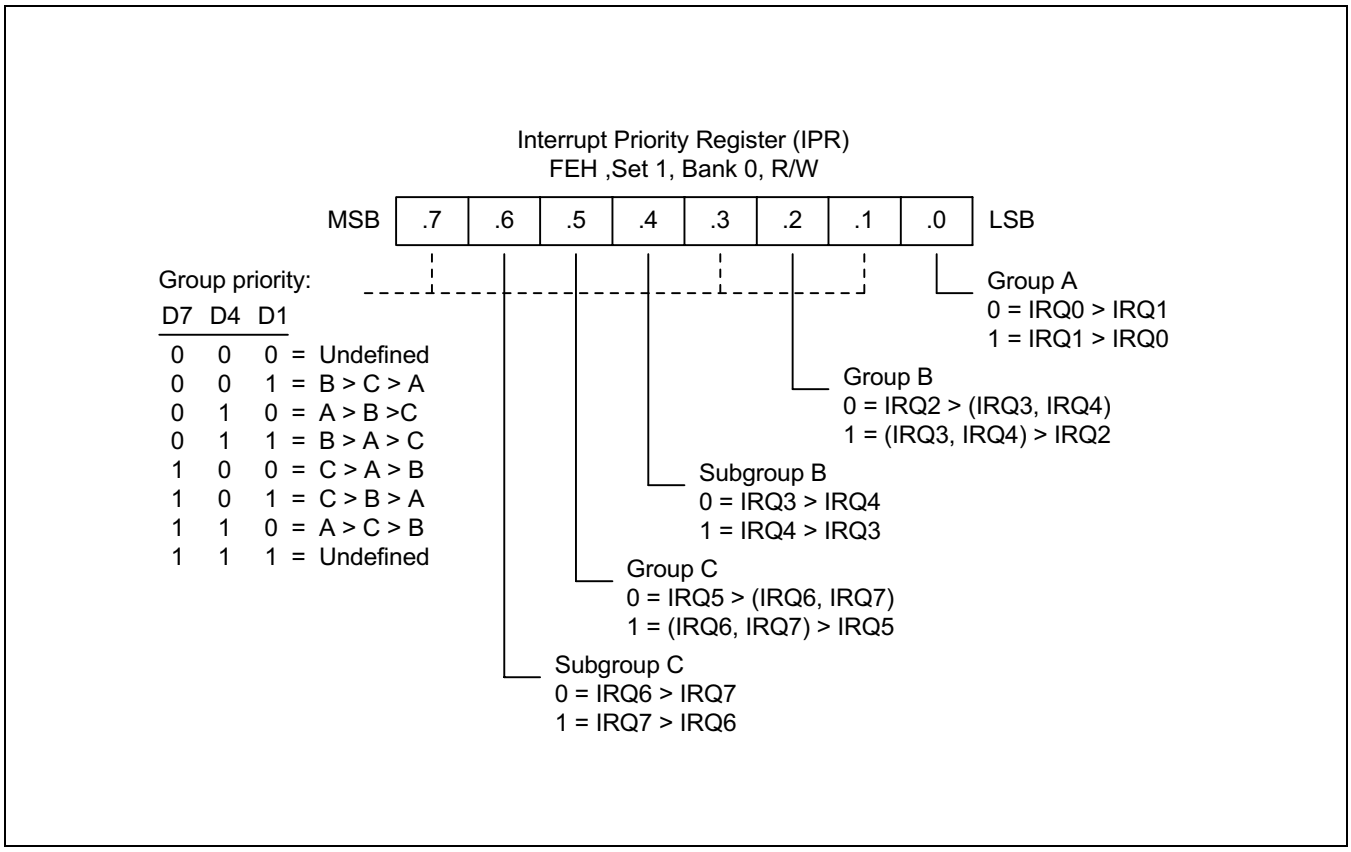

Figure 5-8. Interrupt Priority Register (IPR)

INTERRUPT REQUEST REGISTER (IRQ)

You can poll bit values in the interrupt request register, IRQ (set 1, DCH), to monitor interrupt request status for all levels in the microcontroller's interrupt structure. Each bit corresponds to the interrupt level of the same number: bit 0 to IRQ0, bit 1 to IRQ1, and so on. A "0" indicates that no interrupt request is currently being issued for that level. A "1" indicates that an interrupt request has been generated for that level.

IRQ bit values are read-only addressable using Register addressing mode. You can read (test) the contents of the IRQ register at any time using bit or byte addressing to determine the current interrupt request status of specific interrupt levels. After a reset, all IRQ status bits are cleared to "0".

You can poll IRQ register values even if a DI instruction has been executed (that is, if global interrupt processing is disabled). If an interrupt occurs while the interrupt structure is disabled, the CPU will not service it. You can, however, still detect the interrupt request by polling the IRQ register. In this way, you can determine which events occurred while the interrupt structure was globally disabled.

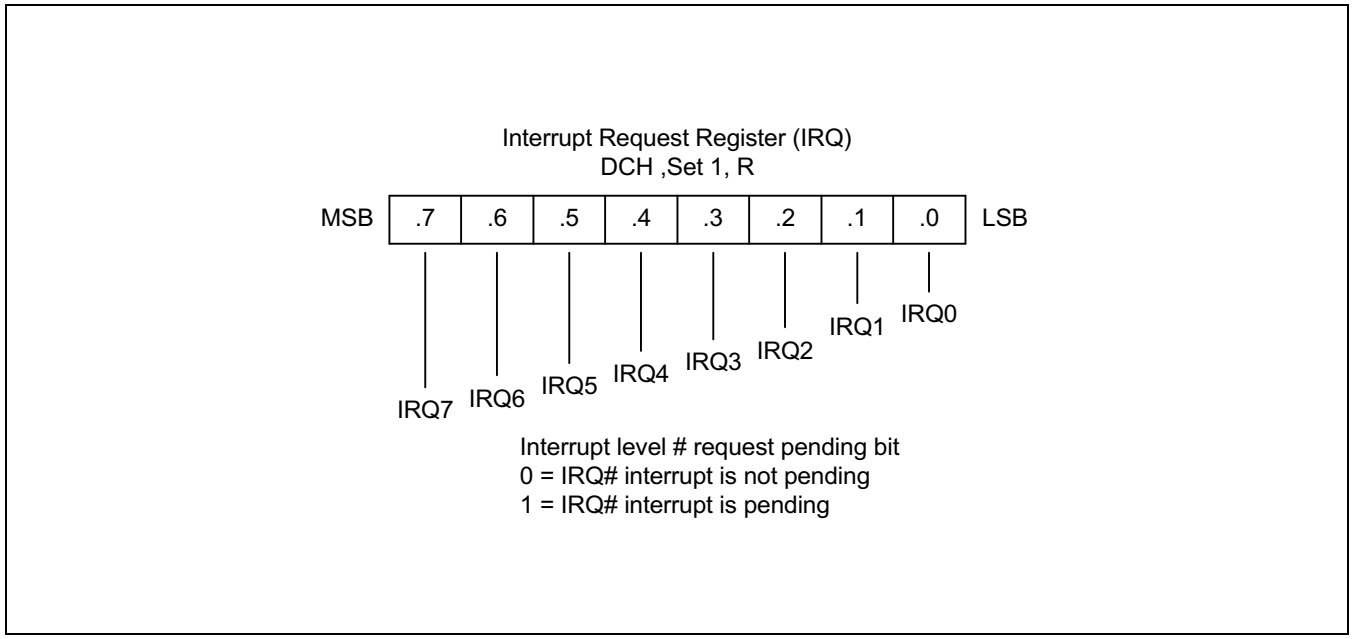

Figure 5-9. Interrupt Request Register (IRQ)

INTERRUPT PENDING FUNCTION TYPES

Overview

There are two types of interrupt pending bits: one type is automatically cleared by hardware after the interrupt service routine is acknowledged and executed; the other must be cleared in the interrupt service routine by software.

Pending Bits Cleared Automatically by Hardware

For interrupt pending bits that are cleared automatically by hardware, interrupt logic sets the corresponding pending bit to "1" when a request occurs. It then issues an IRQ pulse to inform the CPU that an interrupt is waiting to be serviced. The CPU acknowledges the interrupt source by sending an IACK, executes the service routine, and clears the pending bit to "0". This type of pending bit is not mapped and cannot, therefore, be read or written by application software.

In the S3C8238/C8235/F8235 interrupt structure, the timer B underflow interrupt (IRQ1) belongs to this category of interrupts in which pending condition is cleared automatically by hardware.

Pending Bits Cleared by the Service Routine

The second type of pending bit is the one that should be cleared by program software. The service routine must clear the appropriate pending bit before a return-from-interrupt subroutine (IRET) occurs. To do this, a "0" must be written to the corresponding pending bit location in the source's mode or control register.

In the S3C8238/C8235/F8235 interrupt structure, pending conditions for IRQ3, IRQ4 and IRQ7 must be cleared in the interrupt service routine.

INTERRUPT SOURCE POLLING SEQUENCE

The interrupt request polling and servicing sequence is as follows:

1. A source generates an interrupt request by setting the interrupt request bit to "1".
2. The CPU polling procedure identifies a pending condition for that source.
3. The CPU checks the source's interrupt level.
4. The CPU generates an interrupt acknowledge signal.
5. Interrupt logic determines the interrupt's vector address.
6. The service routine starts and the source's pending bit is cleared to "0" (by hardware or by software).
7. The CPU continues polling for interrupt requests.

INTERRUPT SERVICE ROUTINES

Before an interrupt request is serviced, the following conditions must be met:

— Interrupt processing must be globally enabled (EI, SYM.0 = "1")
— The interrupt level must be enabled (IMR register)
— The interrupt level must have the highest priority if more than one levels are currently requesting service
— The interrupt must be enabled at the interrupt's source (peripheral control register)

When all the above conditions are met, the interrupt request is acknowledged at the end of the instruction cycle. The CPU then initiates an interrupt machine cycle that completes the following processing sequence:

1. Reset (clear to "0") the interrupt enable bit in the SYM register (SYM.0) to disable all subsequent interrupts.
2. Save the program counter (PC) and status flags to the system stack.
3. Branch to the interrupt vector to fetch the address of the service routine.
4. Pass control to the interrupt service routine.

When the interrupt service routine is completed, the CPU issues an Interrupt Return (IRET). The IRET restores the PC and status flags, setting SYM.0 to "1". It allows the CPU to process the next interrupt request.

GENERATING INTERRUPT VECTOR ADDRESSES

The interrupt vector area in the ROM (00H–FFH) contains the addresses of interrupt service routines that correspond to each level in the interrupt structure. Vectored interrupt processing follows this sequence:

1. Push the program counter's low-byte value to the stack.
2. Push the program counter's high-byte value to the stack.
3. Push the FLAG register values to the stack.
4. Fetch the service routine's high-byte address from the vector location.
5. Fetch the service routine's low-byte address from the vector location.
6. Branch to the service routine specified by the concatenated 16-bit vector address.

NOTE

A 16-bit vector address always begins at an even-numbered ROM address within the range of 00H–FFH.

NESTING OF VECTORED INTERRUPTS

It is possible to nest a higher-priority interrupt request while a lower-priority request is being serviced. To do this, you must follow these steps:

1. Push the current 8-bit interrupt mask register (IMR) value to the stack (PUSH IMR).
2. Load the IMR register with a new mask value that enables only the higher priority interrupt.
3. Execute an EI instruction to enable interrupt processing (a higher priority interrupt will be processed if it occurs).
4. When the lower-priority interrupt service routine ends, restore the IMR to its original value by returning the previous mask value from the stack (POP IMR).
5. Execute an IRET.

Depending on the application, you may be able to simplify the procedure above to some extent.

NOTES

6 INSTRUCTION SET

OVERVIEW

The instruction set is specifically designed to support large register files that are typical of most S3C8-series microcontrollers. There are 78 instructions. The powerful data manipulation capabilities and features of the instruction set include:

— A full complement of 8-bit arithmetic and logic operations, including multiply and divide
— No special I/O instructions (I/O control/data registers are mapped directly into the register file)
— Decimal adjustment included in binary-coded decimal (BCD) operations
— 16-bit (word) data can be incremented and decremented
— Flexible instructions for bit addressing, rotate, and shift operations

DATA TYPES

The CPU performs operations on bits, bytes, BCD digits, and two-byte words. Bits in the register file can be set, cleared, complemented, and tested. Bits within a byte are numbered from 7 to 0, where bit 0 is the least significant (right-most) bit.

REGISTER ADDRESSING

To access an individual register, an 8-bit address in the range 0–255 or the 4-bit address of a working register is specified. Paired registers can be used to construct 16-bit data, 16-bit program memory or data memory addresses. For detailed information about register addressing, please refer to Chapter 2, "Address Spaces."

ADDRESSING MODES

There are seven explicit addressing modes: Register (R), Indirect Register (IR), Indexed (X), Direct (DA), Relative (RA), Immediate (IM), and Indirect (IA). For detailed descriptions of these addressing modes, please refer to Chapter 3, "Addressing Modes."

Table 6-1. Instruction Group Summary

Mnemonic	Operands	Instruction
Load Instructions		
CLR	dst	Clear
LD	dst,src	Load
LDB	dst,src	Load bit
LDE	dst,src	Load external data memory
LDC	dst,src	Load program memory
LDED	dst,src	Load external data memory and decrement
LDCD	dst,src	Load program memory and decrement
LDEI	dst,src	Load external data memory and increment
LDCI	dst,src	Load program memory and increment
LDEPD	dst,src	Load external data memory with pre-decrement
LDCPD	dst,src	Load program memory with pre-decrement
LDEPI	dst,src	Load external data memory with pre-increment
LDCPI	dst,src	Load program memory with pre-increment
LDW	dst,src	Load word
POP	dst	Pop from stack
POPUD	dst,src	Pop user stack (decrementing)
POPUI	dst,src	Pop user stack (incrementing)
PUSH	src	Push to stack
PUSHUD	dst,src	Push user stack (decrementing)
PUSHUI	dst,src	Push user stack (incrementing)

NOTE: LDE, LDED, LDEI, LDEPP, and LDEPI instructions can be used to read/write the data from the 64-Kbyte data memory.

Table 6-1. Instruction Group Summary (Continued)

Mnemonic	Operands	Instruction

Mnemonic	Operands	Instruction
Rotate and Shift Instructions		
RL	dst	Rotate left
RLC	dst	Rotate left through carry
RR	dst	Rotate right
RRC	dst	Rotate right through carry
SRA	dst	Shift right arithmetic
SWAP	dst	Swap nibbles
CPU Control Instructions		
CCF		Complement carry flag
DI		Disable interrupts
EI		Enable interrupts
IDLE		Enter Idle mode
NOP		No operation
RCF		Reset carry flag
SB0		Set bank 0
SB1		Set bank 1
SCF		Set carry flag
SRP	src	Set register pointers
SRP0	src	Set register pointer 0
SRP1	src	Set register pointer 1
STOP		Enter Stop mode

FLAGS REGISTER (FLAGS)

The flags register FLAGS contains eight bits which describe the current status of CPU operations. Four of these bits, FLAGS.7–FLAGS.4, can be tested and used with conditional jump instructions. Two other flag bits, FLAGS.3 and FLAGS.2, are used for BCD arithmetic.

The FLAGS register also contains a bit to indicate the status of fast interrupt processing (FLAGS.1) and a bank address status bit (FLAGS.0) to indicate whether register bank 0 or bank 1 is currently being addressed.

FLAGS register can be set or reset by instructions as long as its outcome does not affect the flags, such as, Load instruction. Logical and Arithmetic instructions such as, AND, OR, XOR, ADD, and SUB can affect the Flags register. For example, the AND instruction updates the Zero, Sign and Overflow flags based on the outcome of the AND instruction. If the AND instruction uses the Flags register as the destination, then two write will simultaneously occur to the Flags register producing an unpredictable result.

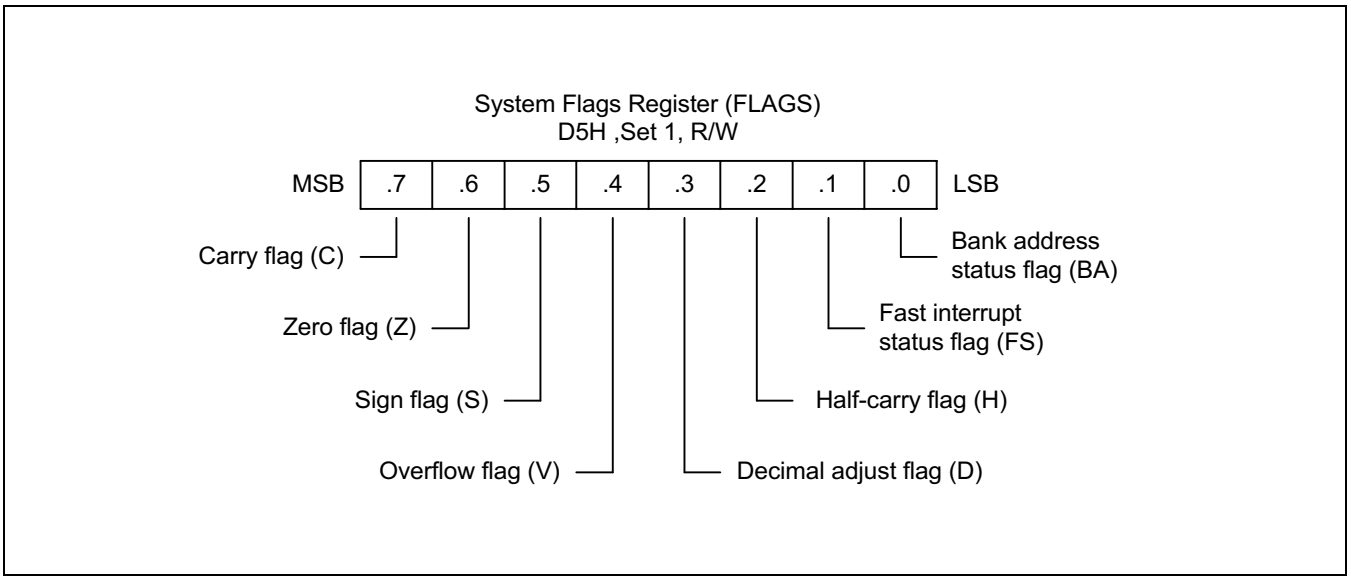

Figure 6-1. System Flags Register (FLAGS)

FLAG DESCRIPTIONS

C Carry Flag (FLAGS.7)

The C flag is set to "1" if the result from an arithmetic operation generates a carry-out from or a borrow to the bit 7 position (MSB). After rotate and shift operations have been performed, it contains the last value shifted out of the specified register. Program instructions can set, clear, or complement the carry flag.

Z Zero Flag (FLAGS.6)

For arithmetic and logic operations, the Z flag is set to "1" if the result of the operation is zero. In operations that test register bits, and in shift and rotate operations, the Z flag is set to "1" if the result is logic zero.

S Sign Flag (FLAGS.5)

Following arithmetic, logic, rotate, or shift operations, the sign bit identifies the state of the MSB of the result. A logic zero indicates a positive number and a logic one indicates a negative number.

V Overflow Flag (FLAGS.4)

The V flag is set to "1" when the result of a two's-complement operation is greater than + 127 or less than – 128. It is cleared to "0" after a logic operation has been performed.

D Decimal Adjust Flag (FLAGS.3)

The DA bit is used to specify what type of instruction was executed last during BCD operations so that a subsequent decimal adjust operation can execute correctly. The DA bit is not usually accessed by programmers, and it cannot be addressed as a test condition.

H Half-Carry Flag (FLAGS.2)

The H bit is set to "1" whenever an addition generates a carry-out of bit 3, or when a subtraction borrows out of bit 4. It is used by the Decimal Adjust (DA) instruction to convert the binary result of a previous addition or subtraction into the correct decimal (BCD) result. The H flag is normally not accessed directly by a program.

FIS Fast Interrupt Status Flag (FLAGS.1)

The FIS bit is set during a fast interrupt cycle and reset during the IRET following interrupt servicing. When set, it inhibits all interrupts and causes the fast interrupt return to be executed when the IRET instruction is executed.

BA Bank Address Flag (FLAGS.0)

The BA flag indicates which register bank in the set 1 area of the internal register file is currently selected, bank 0 or bank 1. The BA flag is cleared to "0" (select bank 0) when the SB0 instruction is executed and is set to "1" (select bank 1) when the SB1 instruction is executed.

INSTRUCTION SET NOTATION

Table 6-2. Flag Notation Conventions

Flag	Description
C	Carry flag
Z	Zero flag
S	Sign flag
V	Overflow flag
D	Decimal-adjust flag
H	Half-carry flag
0	Cleared to logic zero
1	Set to logic one
*	Set or cleared according to operation
–	Value is unaffected
x	Value is undefined

Table 6-3. Instruction Set Symbols

Symbol	Description
dst	Destination operand
src	Source operand
@	Indirect register address prefix
PC	Program counter
IP	Instruction pointer
FLAGS	Flags register (D5H)
RP	Register pointer
#	Immediate operand or register address prefix
H	Hexadecimal number suffix
D	Decimal number suffix
B	Binary number suffix
opc	Opcode

Table 6-4. Instruction Notation Conventions

Notation	Description	Actual Operand Range
cc	Condition code	See list of condition codes in Table 6-6.
r	Working register only	Rn (n = 0–15)
rb	Bit (b) of working register	Rn.b (n = 0–15, b = 0–7)
r0	Bit 0 (LSB) of working register	Rn (n = 0–15)
rr	Working register pair	RRp (p = 0, 2, 4, ..., 14)
R	Register or working register	reg or Rn (reg = 0–255, n = 0–15)
Rb	Bit "b" of register or working register	reg.b (reg = 0–255, b = 0–7)
RR	Register pair or working register pair	reg or RRp (reg = 0–254, even number only, where p = 0, 2, ..., 14)
IA	Indirect addressing mode	addr (addr = 0–254, even number only)
Ir	Indirect working register only	@Rn (n = 0–15)
IR	Indirect register or indirect working register	@Rn or @reg (reg = 0–255, n = 0–15)
Irr	Indirect working register pair only	@RRp (p = 0, 2, ..., 14)
IRR	Indirect register pair or indirect working register pair	@RRp or @reg (reg = 0–254, even only, where p = 0, 2, ..., 14)
X	Indexed addressing mode	#reg[Rn] (reg = 0–255, n = 0–15)
XS	Indexed (short offset) addressing mode	#addr[RRp] (addr = range –128 to +127, where p = 0, 2, ..., 14)
XL	Indexed (long offset) addressing mode	#addr [RRp] (addr = range 0–65535, where p = 2, ..., 14)
DA	Direct addressing mode	addr (addr = range 0–65535)
RA	Relative addressing mode	addr (addr = a number from +127 to –128 that is an offset relative to the address of the next instruction)
IM	Immediate addressing mode	#data (data = 0–255)
IML	Immediate (long) addressing mode	#data (data = 0–65535)

CONDITION CODES

The opcode of a conditional jump always contains a 4-bit field called the condition code (cc). This specifies under which conditions it is to execute the jump. For example, a conditional jump with the condition code for "equal" after a compare operation only jumps if the two operands are equal. Condition codes are listed in Table 6-6.

The carry (C), zero (Z), sign (S), and overflow (V) flags are used to control the operation of conditional jump instructions.

Table 6-6. Condition Codes

Binary	Mnemonic	Description	Flags Set
0000	F	Always false	–
1000	T	Always true	–
0111 (1)	C	Carry	C = 1
1111 (1)	NC	No carry	C = 0
0110 (1)	Z	Zero	Z = 1
1110 (1)	NZ	Not zero	Z = 0
1101	PL	Plus	S = 0
0101	MI	Minus	S = 1
0100	OV	Overflow	V = 1
1100	NOV	No overflow	V = 0
0110 (1)	EQ	Equal	Z = 1
1110 (1)	NE	Not equal	Z = 0
1001	GE	Greater than or equal	(S XOR V) = 0
0001	LT	Less than	(S XOR V) = 1
1010	GT	Greater than	(Z OR (S XOR V)) = 0
0010	LE	Less than or equal	(Z OR (S XOR V)) = 1
1111 (1)	UGE	Unsigned greater than or equal	C = 0
0111 (1)	ULT	Unsigned less than	C = 1
1011	UGT	Unsigned greater than	(C = 0 AND Z = 0) = 1
0011	ULE	Unsigned less than or equal	(C OR Z) = 1

NOTES:

1. It indicate condition codes which are related to two different mnemonics but which test the same flag. For example, Z and EQ are both true if the zero flag (Z) is set, but after an ADD instruction, Z would probably be used. Following a CP instruction, you would probably want to use the instruction EQ.
2. For operations using unsigned numbers, the special condition codes UGE, ULT, UGT, and ULE must be used.

INSTRUCTION DESCRIPTIONS

This Chapter contains detailed information and programming examples for each instruction in the S3C8-series instruction set. Information is arranged in a consistent format for improved readability and for quick reference. The following information is included in each instruction description:

— Instruction name (mnemonic)
— Full instruction name
— Source/destination format of the instruction operand
— Shorthand notation of the instruction's operation
— Textual description of the instruction's effect
— Flag settings that may be affected by the instruction
— Detailed description of the instruction's format, execution time, and addressing mode(s)
— Programming example(s) explaining how to use the instruction

ADC — Add with Carry

ADC dst,src

Operation: dst ← dst + src + c

The source operand, along with the carry flag setting, is added to the destination operand and the sum is stored in the destination. The contents of the source are unaffected. Two's-complement addition is performed. In multiple-precision arithmetic, this instruction lets the carry value from the addition of low-order operands be carried into the addition of high-order operands.

Flags:

C: Set if there is a carry from the most significant bit of the result; cleared otherwise.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result is negative; cleared otherwise.

V: Set if arithmetic overflow occurs, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise.

D: Always cleared to "0".

H: Set if there is a carry from the most significant bit of the low-order four bits of the result; cleared otherwise.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | src		2	4	12	r	r
				6	13	r	lr
opc	src	dst	3	6	14	R	R
					15	R	IR
opc	dst	src	3	6	16	R	IM

Examples: Given: R1 = 10H, R2 = 03H, C flag = "1", register 01H = 20H, register 02H = 03H, and register 03H = 0AH:

```
ADC     R1,R2       →     R1 = 14H, R2 = 03H
ADC     R1,@R2      →     R1 = 1BH, R2 = 03H
ADC     01H,02H     →     Register 01H = 24H, register 02H = 03H
ADC     01H,@02H    →     Register 01H = 2BH, register 02H = 03H
ADC     01H,#11H    →     Register 01H = 32H
```

In the first example, the destination register R1 contains the value 10H, the carry flag is set to "1" and the source working register R2 contains the value 03H. The statement "ADC R1,R2" adds 03H and the carry flag value ("1") to the destination value 10H, leaving 14H in the register R1.

ADD — Add

ADD dst,src

Operation: dst ← dst + src

The source operand is added to the destination operand and the sum is stored in the destination. The contents of the source are unaffected. Two's-complement addition is performed.

Flags:

C: Set if there is a carry from the most significant bit of the result; cleared otherwise.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result is negative; cleared otherwise.

V: Set if arithmetic overflow occurred, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise.

D: Always cleared to "0".

H: Set if a carry from the low-order nibble occurred.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc | dst | src	2	4	02	r	r
		6	03	r	lr
opc | src | dst	3	6	04	R	R
			05	R	IR
opc | dst | src	3	6	06	R	IM

Examples: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

ADD	R1,R2	→	R1 = 15H, R2 = 03H
ADD	R1,@R2	→	R1 = 1CH, R2 = 03H
ADD	01H,02H	→	Register 01H = 24H, register 02H = 03H
ADD	01H,@02H	→	Register 01H = 2BH, register 02H = 03H
ADD	01H,#25H	→	Register 01H = 46H

In the first example, the destination working register R1 contains 12H and the source working register R2 contains 03H. The statement "ADD R1,R2" adds 03H to 12H, leaving the value 15H in the register R1.

AND — Logical AND

AND dst,src

Operation: dst ← dst AND src

The source operand is logically ANDed with the destination operand. The result is stored in the destination. The AND operation causes a "1" bit to be stored whenever the corresponding bits in the two operands are both logic ones; otherwise a "0" bit value is stored. The contents of the source are unaffected.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Always cleared to "0".

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src		2	4	52	r	r
				6	53	r	lr
opc	src	dst	3	6	54	R	R
					55	R	IR
opc	dst	src	3	6	56	R	IM

Examples: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

AND	R1,R2	→	R1 = 02H, R2 = 03H
AND	R1,@R2	→	R1 = 02H, R2 = 03H
AND	01H,02H	→	Register 01H = 01H, register 02H = 03H
AND	01H,@02H	→	Register 01H = 00H, register 02H = 03H
AND	01H,#25H	→	Register 01H = 21H

In the first example, the destination working register R1 contains the value 12H and the source working register R2 contains 03H. The statement "AND R1,R2" logically ANDs the source operand 03H with the destination operand value 12H, leaving the value 02H in the register R1.

BAND — Bit AND

BAND dst,src.b

BAND dst.b,src

Operation: dst(0) ← dst(0) AND src(b)
or
dst(b) ← dst(b) AND src(0)

The specified bit of the source (or the destination) is logically ANDed with the zero bit (LSB) of the destination (or the source). The resultant bit is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags:
C: Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Cleared to "0".
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | b | 0	src	3	6	67	r0	Rb
opc	src | b | 1	dst	3	6	67	Rb	r0

NOTE: In the second byte of the 3-byte instruction formats, the destination (or the source) address is four bits, the bit address "b" is three bits, and the LSB address value is one bit in length.

Examples: Given: R1 = 07H and register 01H = 05H:

```
BAND    R1,01H.1    →    R1 = 06H, register 01H = 05H
BAND    01H.1,R1    →    Register 01H = 05H, R1 = 07H
```

In the first example, the source register 01H contains the value 05H (00000101B) and the destination working register R1 contains 07H (00000111B). The statement "BAND R1,01H.1" ANDs the bit 1 value of the source register ("0") with the bit 0 value of the register R1 (destination), leaving the value 06H (00000110B) in the register R1.

BCP — Bit Compare

BCP dst,src.b

Operation: dst(0) – src(b)

The specified bit of the source is compared to (subtracted from) bit zero (LSB) of the destination. The zero flag is set if the bits are the same; otherwise it is cleared. The contents of both operands are unaffected by the comparison.

Flags:

C: Unaffected.

Z: Set if the two bits are the same; cleared otherwise.

S: Cleared to "0".

V: Undefined.

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | b | 0	src	3	6	17	r0	Rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address "0" is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H and register 01H = 01H:

BCP R1,01H.1 → R1 = 07H, register 01H = 01H

If the destination working register R1 contains the value 07H (00000111B) and the source register 01H contains the value 01H (00000001B), the statement "BCP R1,01H.1" compares bit one of the source register (01H) and bit zero of the destination register (R1). Because the bit values are not identical, the zero flag bit (Z) is cleared in the FLAGS register (0D5H).

BITC — Bit Complement

BITC dst.b

Operation: dst(b) ← NOT dst(b)

This instruction complements the specified bit within the destination without affecting any other bit in the destination.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Cleared to "0".

V: Undefined.

D: Unaffected.

H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc | dst | b | 0	2	4	57	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address “b” is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H

BITC R1.1 → R1 = 05H

If the working register R1 contains the value 07H (00000111B), the statement "BITC R1.1" complements bit one of the destination and leaves the value 05H (00000101B) in the register R1. Because the result of the complement is not "0", the zero flag (Z) in the FLAGS register (0D5H) is cleared.

BITR — Bit Reset

BITR dst.b

Operation: dst(b) ← 0

The BITR instruction clears the specified bit within the destination without affecting any other bit in the destination.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc | dst | b | 0	2	4	77	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address “0” is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BITR R1.1 → R1 = 05H

If the value of the working register R1 is 07H (00000111B), the statement "BITR R1.1" clears bit one of the destination register R1, leaving the value 05H (00000101B).

BITS — Bit Set

BITS dst.b

Operation: dst(b) ← 1

The BITS instruction sets the specified bit within the destination without affecting any other bit in the destination.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst | b | 1	2	4	77	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address “b” is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BITS R1.3 → R1 = 0FH

If the working register R1 contains the value 07H (00000111B), the statement "BITS R1.3" sets bit three of the destination register R1 to "1", leaving the value 0FH (00001111B).

BOR — Bit OR

BOR dst,src.b

BOR dst.b,src

Operation: dst(0) ← dst(0) OR src(b)

or

dst(b) ← dst(b) OR src(0)

The specified bit of the source (or the destination) is logically ORed with bit zero (LSB) of the destination (or the source). The resulting bit value is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: **C:** Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Cleared to "0".

V: Undefined.

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | b | 0	src	3	6	07	r0	Rb
opc	src | b | 1	dst	3	6	07	Rb	r0

NOTE: In the second byte of the 3-byte instruction format, the destination (or the source) address is four bits, the bit address “b” is three bits, and the LSB address value is one bit.

Examples: Given: R1 = 07H and register 01H = 03H:

```
BOR     R1, 01H.1    →    R1 = 07H, register 01H = 03H
BOR     01H.2, R1    →    Register 01H = 07H, R1 = 07H
```

In the first example, the destination working register R1 contains the value 07H (00000111B) and the source register 01H the value 03H (00000011B). The statement "BOR R1,01H.1" logically ORs bit one of the register 01H (source) with bit zero of R1 (destination). This leaves the same value (07H) in the working register R1.

In the second example, the destination register 01H contains the value 03H (00000011B) and the source working register R1 the value 07H (00000111B). The statement "BOR 01H.2,R1" logically ORs bit two of the register 01H (destination) with bit zero of R1 (source). This leaves the value 07H in the register 01H.

BTJRF — Bit Test, Jump Relative on False

BTJRF dst,src.b

Operation: If src(b) is a "0", then PC ← PC + dst

The specified bit within the source operand is tested. If it is a "0", the relative address is added to the program counter and control passes to the statement whose address is currently in the program counter. Otherwise, the instruction following the BTJRF instruction is executed.

Flags: No flags are affected.

Format:

(note)			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src | b | 0	dst	3	10	37	RA	rb

NOTE: In the second byte of the instruction format, the source address is four bits, the bit address "b" is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BTJRF SKIP,R1.3 → PC jumps to SKIP location

If the working register R1 contains the value 07H (00000111B), the statement "BTJRF SKIP,R1.3" tests bit 3. Because it is "0", the relative address is added to the PC and the PC jumps to the memory location pointed to by the SKIP (Remember that the memory location must be within the allowed range of + 127 to – 128).

BTJRT — Bit Test, Jump Relative on True

BTJRT dst,src.b

Operation: If src(b) is a "1", then PC ← PC + dst

The specified bit within the source operand is tested. If it is a "1", the relative address is added to the program counter and control passes to the statement whose address is now in the PC. Otherwise, the instruction following the BTJRT instruction is executed.

Flags: No flags are affected.

Format:

(note)			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	src | b | 1	dst	3	10	37	RA	rb

NOTE: In the second byte of the instruction format, the source address is four bits, the bit address "b" is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BTJRT SKIP,R1.1

If the working register R1 contains the value 07H (00000111B), the statement "BTJRT SKIP,R1.1" tests bit one in the source register (R1). Because it is a "1", the relative address is added to the PC and the PC jumps to the memory location pointed to by the SKIP.

Remember that the memory location addressed by the BTJRT instruction must be within the allowed range of + 127 to – 128.

BXOR — Bit XOR

BXOR dst,src.b

BXOR dst.b,src

Operation: dst(0) ← dst(0) XOR src(b)
or
dst(b) ← dst(b) XOR src(0)

The specified bit of the source (or the destination) is logically exclusive-ORed with bit zero (LSB) of the destination (or the source). The result bit is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags:
C: Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Cleared to "0".
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | b | 0	src	3	6	27	r0	Rb
opc	src | b | 1	dst	3	6	27	Rb	r0

NOTE: In the second byte of the 3-byte instruction format, the destination (or the source) address is four bits, the bit address "b" is three bits, and the LSB address value is one bit in length.

Examples: Given: R1 = 07H (00000111B) and register 01H = 03H (00000011B):

```
BXOR    R1,01H.1    →    R1 = 06H, register 01H = 03H
BXOR    01H.2,R1    →    Register 01H = 07H, R1 = 07H
```

In the first example, the destination working register R1 has the value 07H (00000111B) and the source register 01H has the value 03H (00000011B). The statement "BXOR R1,01H.1" exclusive-ORs bit one of the register 01H (the source) with bit zero of R1 (the destination). The result bit value is stored in bit zero of R1, changing its value from 07H to 06H. The value of the source register 01H is unaffected.

CALL — Call Procedure

CALL dst

Operation: SP ← SP–1
@SP ← PCL
SP ← SP–1
@SP ← PCH
PC ← dst

The contents of the program counter are pushed onto the top of the stack. The program counter value used is the address of the first instruction following the CALL instruction. The specified destination address is then loaded into the program counter and points to the first instruction of a procedure. At the end of the procedure the return instruction (RET) can be used to return to the original program flow. RET pops the top of the stack back into the program counter.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc | dst	3	14	F6	DA
opc | dst	2	12	F4	IRR
opc | dst	2	14	D4	IA

Examples: Given: R0 = 35H, R1 = 21H, PC = 1A47H, and SP = 0002H:

CALL	3521H	→	SP = 0000H (Memory locations 0000H = 1AH, 0001H = 4AH, where, 4AH is the address that follows the instruction.)
CALL	@RR0	→	SP = 0000H (0000H = 1AH, 0001H = 49H)
CALL	#40H	→	SP = 0000H (0000H = 1AH, 0001H = 49H)

In the first example, if the program counter value is 1A47H and the stack pointer contains the value 0002H, the statement "CALL 3521H" pushes the current PC value onto the top of the stack. The stack pointer now points to the memory location 0000H. The PC is then loaded with the value 3521H, the address of the first instruction in the program sequence to be executed.

If the contents of the program counter and the stack pointer are the same as in the first example, the statement "CALL @RR0" produces the same result except that the 49H is stored in stack location 0001H (because the two-byte instruction format was used). The PC is then loaded with the value 3521H, the address of the first instruction in the program sequence to be executed. Assuming that the contents of the program counter and the stack pointer are the same as in the first example, if the program address 0040H contains 35H and the program address 0041H contains 21H, the statement "CALL #40H" produces the same result as in the second example.

CCF — Complement Carry Flag

CCF

Operation: C ← NOT C

The carry flag (C) is complemented. If C = "1", the value of the carry flag is changed to logic zero. If C = "0", the value of the carry flag is changed to logic one.

Flags: **C:** Complemented.

No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	EF

Example: Given: The carry flag = "0":

CCF

If the carry flag = "0", the CCF instruction complements it in the FLAGS register (0D5H), changing its value from logic zero to logic one.

CLR — Clear

CLR dst

Operation: dst ← "0"

The destination location is cleared to "0".

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc dst	2	4	B0	R
		4	B1	IR

Examples: Given: Register 00H = 4FH, register 01H = 02H, and register 02H = 5EH:

```
CLR   00H   →   Register 00H = 00H
CLR   @01H  →   Register 01H = 02H, register 02H = 00H
```

In Register (R) addressing mode, the statement "CLR 00H" clears the destination register 00H value to 00H.

In the second example, the statement "CLR @01H" uses Indirect Register (IR) addressing mode to clear the 02H register value to 00H.

COM — Complement

COM dst

Operation: dst ← NOT dst

The contents of the destination location are complemented (one's complement). All "1s" are changed to "0s", and vice-versa.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Always reset to "0".

D: Unaffected.

H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	4	60	R
			4	61	IR

Examples: Given: R1 = 07H and register 07H = 0F1H:

```
COM     R1      →     R1 = 0F8H
COM     @R1     →     R1 = 07H, register 07H = 0EH
```

In the first example, the destination working register R1 contains the value 07H (00000111B). The statement "COM R1" complements all the bits in R1: all logic ones are changed to logic zeros, and logic zeros to logic ones, leaving the value 0F8H (11111000B).

In the second example, Indirect Register (IR) addressing mode is used to complement the value of the destination register 07H (11110001B), leaving the new value 0EH (00001110B).

CP — Compare

CP dst,src

Operation: dst–src

The source operand is compared to (subtracted from) the destination operand, and the appropriate flags are set accordingly. The contents of both operands are unaffected by the comparison.

Flags:

C: Set if a "borrow" occurred (src > dst); cleared otherwise.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result is negative; cleared otherwise.

V: Set if arithmetic overflow occurred; cleared otherwise.

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | src		2	4	A2	r	r
				6	A3	r	lr
opc	src	dst	3	6	A4	R	R
				6	A5	R	IR
opc	dst	src	3	6	A6	R	IM

Examples: 1. Given: R1 = 02H and R2 = 03H:

```
CP      R1,R2      →      Set the C and S flags
```

The destination working register R1 contains the value 02H and the source register R2 contains the value 03H. The statement "CP R1,R2" subtracts the R2 value (source/subtrahend) from the R1 value (destination/minuend). Because a "borrow" occurs and the difference is negative, the C and the S flag values are "1".

2. Given: R1 = 05H and R2 = 0AH:

```
CP      R1,R2
JP      UGE,SKIP
INC     R1
SKIP    LD  R3,R1
```

In this example, the destination working register R1 contains the value 05H which is less than the contents of the source working register R2 (0AH). The statement "CP R1,R2" generates C = "1" and the JP instruction does not jump to the SKIP location. After the statement "LD R3,R1" executes, the value 06H remains in the working register R3.

CPIJE — Compare, Increment, and Jump on Equal

CPIJE dst,src,RA

Operation: If dst–src = "0", PC ← PC + RA
Ir ← Ir + 1

The source operand is compared to (subtracted from) the destination operand. If the result is "0", the relative address is added to the program counter and control passes to the statement whose address is now in the program counter. Otherwise, the instruction immediately following the CPIJE instruction is executed. In either case, the source pointer is incremented by one before the next instruction is executed.

Flags: No flags are affected.

Format:

				Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	RA	3	12	C2	r	Ir

Example: Given: R1 = 02H, R2 = 03H, and register 03H = 02H:

CPIJE R1,@R2,SKIP → R2 = 04H, PC jumps to SKIP location

In this example, the working register R1 contains the value 02H, the working register R2 the value 03H, and the register 03 contains 02H. The statement "CPIJE R1,@R2,SKIP" compares the @R2 value 02H (00000010B) to 02H (00000010B). Because the result of the comparison is *equal*, the relative address is added to the PC and the PC then jumps to the memory location pointed to by SKIP. The source register (R2) is incremented by one, leaving a value of 04H.

Remember that the memory location addressed by the CPIJE instruction must be within the allowed range of + 127 to – 128.

CPIJNE — Compare, Increment, and Jump on Non-Equal

CPIJNE dst,src,RA

Operation: If dst–src ≠ "0", PC ← PC + RA
lr ← lr + 1

The source operand is compared to (subtracted from) the destination operand. If the result is not "0", the relative address is added to the program counter and control passes to the statement whose address is now in the program counter. Otherwise the instruction following the CPIJNE instruction is executed. In either case the source pointer is incremented by one before the next instruction.

Flags: No flags are affected.

Format:

				Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src	dst	RA	3	12	D2	r	lr

Example: Given: R1 = 02H, R2 = 03H, and register 03H = 04H:

CPIJNE R1,@R2,SKIP → R2 = 04H, PC jumps to SKIP location

The working register R1 contains the value 02H, the working register R2 (the source pointer) the value 03H, and the general register 03 the value 04H. The statement "CPIJNE R1,@R2,SKIP" subtracts 04H (00000100B) from 02H (00000010B). Because the result of the comparison is *non-equal*, the relative address is added to the PC and the PC then jumps to the memory location pointed to by SKIP. The source pointer register (R2) is also incremented by one, leaving a value of 04H.

Remember that the memory location addressed by the CPIJNE instruction must be within the allowed range of + 127 to – 128.

DA — Decimal Adjust

DA dst

Operation: dst ← DA dst

The destination operand is adjusted to form two 4-bit BCD digits following an addition or subtraction operation. For addition (ADD, ADC) or subtraction (SUB, SBC), the following table indicates the operation performed (The operation is undefined if the destination operand is not the result of a valid addition or subtraction of BCD digits):

Instruction	Carry Before DA	Bits 4–7 Value (Hex)	H Flag Before DA	Bits 0–3 Value (Hex)	Number Added to Byte	Carry After DA
	0	0–9	0	0–9	00	0
	0	0–8	0	A–F	06	0
	0	0–9	1	0–3	06	0
ADD	0	A–F	0	0–9	60	1
ADC	0	9–F	0	A–F	66	1
	0	A–F	1	0–3	66	1
	1	0–2	0	0–9	60	1
	1	0–2	0	A–F	66	1
	1	0–3	1	0–3	66	1
	0	0–9	0	0–9	00 = – 00	0
SUB	0	0–8	1	6–F	FA = – 06	0
SBC	1	7–F	0	0–9	A0 = – 60	1
	1	6–F	1	6–F	9A = – 66	1

Flags:
C: Set if there was a carry from the most significant bit; cleared otherwise (see table).
Z: Set if result is "0"; cleared otherwise.
S: Set if result bit 7 is set; cleared otherwise.
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

opc	dst

Bytes	Cycles	Opcode (Hex)	Addr Mode dst
2	4	40	R
	4	41	IR

DA — Decimal Adjust

DA (Continued)

Example: Given: The working register R0 contains the value 15 (BCD), the working register R1 contains 27 (BCD), and the address 27H contains 46 (BCD):

```
ADD     R1,R0       ;       C ← "0", H ← "0", Bits 4–7 = 3, bits 0–3 = C, R1 ← 3CH
DA      R1          ;       R1 ← 3CH + 06
```

If an addition is performed using the BCD values 15 and 27, the result should be 42. The sum is incorrect, however, when the binary representations are added in the destination location using the standard binary arithmetic:

```
  0 0 0 1   0 1 0 1       15
+ 0 0 1 0   0 1 1 1       27
  0 0 1 1   1 1 0 0   =3CH
```

The DA instruction adjusts this result so that the correct BCD representation is obtained:

```
  0 0 1 1   1 1 0 0
+ 0 0 0 0   0 1 1 0
  0 1 0 0   0 0 1 0   =42
```

Assuming the same values given above, the statements

```
SUB     27H,R0      ;       C ← "0", H ← "0", Bits 4–7 = 3, bits 0–3 = 1
DA      @R1         ;       @R1 ← 31–0
```

leave the value 31 (BCD) in the address 27H (@R1).

DEC — Decrement

DEC dst

Operation: dst ← dst–1

The contents of the destination operand are decremented by one.

Flags:
C: Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc dst	2	4	00	R
		4	01	IR

Examples: Given: R1 = 03H and register 03H = 10H:

```
DEC     R1      →     R1 = 02H
DEC     @R1     →     Register 03H = 0FH
```

In the first example, if the working register R1 contains the value 03H, the statement "DEC R1" decrements the hexadecimal value by one, leaving the value 02H. In the second example, the statement "DEC @R1" decrements the value 10H contained in the destination register 03H by one, leaving the value 0FH.

DECW — Decrement Word

DECW dst

Operation: dst ← dst – 1

The contents of the destination location (which must be an even address) and the operand following that location are treated as a single 16-bit value that is decremented by one.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result is negative; cleared otherwise.

V: Set if arithmetic overflow occurred; cleared otherwise.

D: Unaffected.

H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	8	80	RR
			8	81	IR

Examples: Given: R0 = 12H, R1 = 34H, R2 = 30H, register 30H = 0FH, and register 31H = 21H:

```
DECW    RR0     →    R0 = 12H, R1 = 33H
DECW    @R2     →    Register 30H = 0FH, register 31H = 20H
```

In the first example, the destination register R0 contains the value 12H and the register R1 the value 34H. The statement "DECW RR0" addresses R0 and the following operand R1 as a 16-bit word and decrements the value of R1 by one, leaving the value 33H.

NOTE: A system malfunction may occur if you use a Zero flag (FLAGS.6) result together with a DECW instruction. To avoid this problem, it is recommended to use DECW as shown in the following example.

```
LOOP    DECW    RR0
LD      R2,R1
OR      R2,R0
JR      NZ,LOOP
```

DI — Disable Interrupts

DI

Operation: SYM (0) ← 0

Bit zero of the system mode control register, SYM.0, is cleared to "0", globally disabling all interrupt processing. Interrupt requests will continue to set their respective interrupt pending bits, but the CPU will not service them while interrupt processing is disabled.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	8F

Example: Given: SYM = 01H:

DI

If the value of the SYM register is 01H, the statement "DI" leaves the new value 00H in the register and clears SYM.0 to "0", disabling interrupt processing.

DIV — Divide (Unsigned)

DIV dst,src

Operation: dst ÷ src
dst (UPPER) ← REMAINDER
dst (LOWER) ← QUOTIENT

The destination operand (16 bits) is divided by the source operand (8 bits). The quotient (8 bits) is stored in the lower half of the destination. The remainder (8 bits) is stored in the upper half of the destination. When the quotient is ≥ 28, the numbers stored in the upper and lower halves of the destination for quotient and remainder are incorrect. Both operands are treated as unsigned integers.

Flags:
C: Set if the V flag is set and the quotient is between 28 and 29 –1; cleared otherwise.
Z: Set if the divisor or the quotient = "0"; cleared otherwise.
S: Set if MSB of the quotient = "1"; cleared otherwise.
V: Set if the quotient is ≥ 28 or if the divisor = "0"; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

opc	src	dst

Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
3	26/10 *	94	RR	R
	26/10 *	95	RR	IR
	26/10 *	96	RR	IM

* Execution takes 10 cycles if the divide-by-zero is attempted, otherwise, it takes 26 cycles.

Examples: Given: R0 = 10H, R1 = 03H, R2 = 40H, register 40H = 80H:

DIV RR0,R2 → R0 = 03H, R1 = 40H
DIV RR0,@R2 → R0 = 03H, R1 = 20H
DIV RR0,#20H → R0 = 03H, R1 = 80H

In the first example, the destination working register pair RR0 contains the values 10H (R0) and 03H (R1), and the register R2 contains the value 40H. The statement "DIV RR0,R2" divides the 16-bit RR0 value by the 8-bit value of the R2 (source) register. After the DIV instruction, R0 contains the value 03H and R1 contains 40H. The 8-bit remainder is stored in the upper half of the destination register RR0 (R0) and the quotient in the lower half (R1).

DJNZ — Decrement and Jump if Non-Zero

DJNZ r,dst

Operation: r ← r – 1
If r ≠ 0, PC ← PC + dst

The working register being used as a counter is decremented. If the contents of the register are not logic zero after decrementing, the relative address is added to the program counter and control passes to the statement whose address is now in the PC. The range of the relative address is + 127 to – 128, and the original value of the PC is taken to be the address of the instruction byte following the DJNZ statement.

NOTE: In case of using DJNZ instruction, the working register being used as a counter should be set at the one of location 0C0H to 0CFH with SRP, SRP0 or SRP1 instruction.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
r | opc	dst	2	8 (jump taken)	rA	RA
			8 (no jump)	r = 0 to F	

Example: Given: R1 = 02H and LOOP is the label of a relative address:

```
SRP     #0C0H
DJNZ    R1,LOOP
```

DJNZ is typically used to control a "loop" of instructions. In many cases, a label is used as the destination operand instead of a numeric relative address value. In the example, the working register R1 contains the value 02H, and LOOP is the label for a relative address.

The statement "DJNZ R1, LOOP" decrements the register R1 by one, leaving the value 01H. Because the contents of R1 after the decrement are non-zero, the jump is taken to the relative address specified by the LOOP label.

EI — Enable Interrupts

EI

Operation: SYM (0) ← 1

The EI instruction sets bit zero of the system mode register, SYM.0 to "1". This allows interrupts to be serviced as they occur (assuming they have the highest priority). If an interrupt's pending bit was set while interrupt processing was disabled (by executing a DI instruction), it will be serviced when the EI instruction is executed.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	9F

Example: Given: SYM = 00H:

EI

If the SYM register contains the value 00H, that is, if interrupts are currently disabled, the statement "EI" sets the SYM register to 01H, enabling all interrupts. (SYM.0 is the enable bit for global interrupt processing.)

ENTER — Enter

ENTER

Operation: SP ← SP – 2
@SP ← IP
IP ← PC
PC ← @IP
IP ← IP + 2

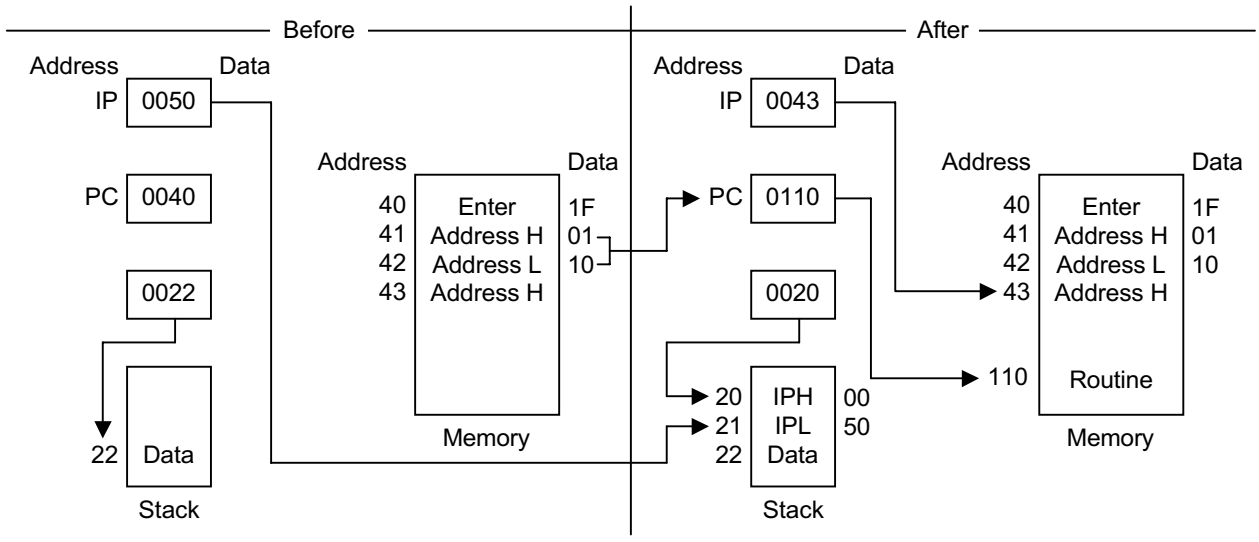
This instruction is useful when implementing threaded-code languages. The contents of the instruction pointer are pushed to the stack. The program counter (PC) value is then written to the instruction pointer. The program memory word that is pointed to by the instruction pointer is loaded into the PC, and the instruction pointer is incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	14	1F

Example: The diagram below shows an example of how to use an ENTER statement.



EXIT — Exit

EXIT

Operation: IP ← @SP
SP ← SP + 2
PC ← @IP
IP ← IP + 2

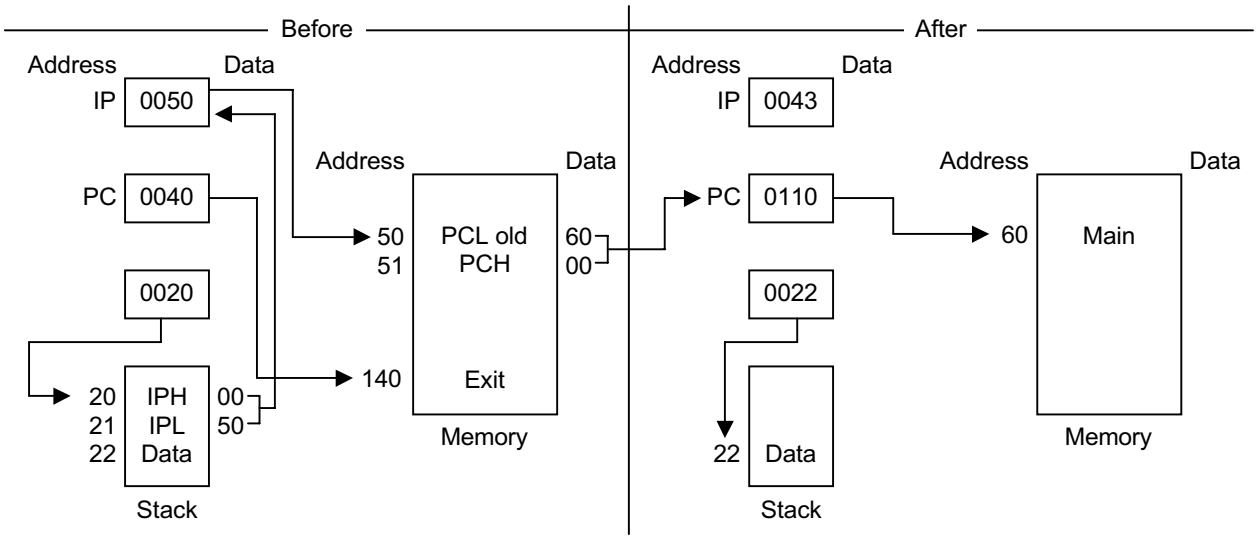
This instruction is useful when implementing threaded-code languages. The stack value is popped and loaded into the instruction pointer. The program memory word that is pointed to by the instruction pointer is then loaded into the program counter, and the instruction pointer is incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	16	2F

Example: The diagram below shows an example of how to use an EXIT statement.



IDLE — Idle Operation

IDLE

Operation: (See description)

The IDLE instruction stops the CPU clock while allowing the system clock oscillation to continue. Idle mode can be released by an interrupt request (IRQ) or an external reset operation.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	1	4	6F	–	–

Example: The instruction **IDLE** stops the CPU clock but it does not stop the system clock.

INC — Increment

INC dst

Operation: dst ← dst + 1

The contents of the destination operand are incremented by one.

Flags:
C: Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
dst | opc	1	4	rE	r
			r = 0 to F	
opc dst	2	4	20	R
		4	21	IR

Examples: Given: R0 = 1BH, register 00H = 0CH, and register 1BH = 0FH:

```
INC R0      → R0 = 1CH
INC 00H     → Register 00H = 0DH
INC @R0     → R0 = 1BH, register 01H = 10H
```

In the first example, if the destination working register R0 contains the value 1BH, the statement "INC R0" leaves the value 1CH in that same register.

The second example shows the effect an INC instruction has on the register at the location 00H, assuming that it contains the value 0CH.

In the third example, INC is used in Indirect Register (IR) addressing mode to increment the value of the register 1BH from 0FH to 10H.

INCW — Increment Word

INCW dst

Operation: dst ← dst + 1

The contents of the destination (which must be an even address) and the byte following that location are treated as a single 16-bit value that is incremented by one.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result is negative; cleared otherwise.

V: Set if arithmetic overflow occurred; cleared otherwise.

D: Unaffected.

H: Unaffected.

Format:

opc	dst

Bytes	Cycles	Opcode (Hex)	Addr Mode dst
2	8	A0	RR
	8	A1	IR

Examples: Given: R0 = 1AH, R1 = 02H, register 02H = 0FH, and register 03H = 0FFH:

```
INCW    RR0     →    R0 = 1AH, R1 = 03H
INCW    @R1     →    Register 02H = 10H, register 03H = 00H
```

In the first example, the working register pair RR0 contains the value 1AH in the register R0 and 02H in the register R1. The statement "INCW RR0" increments the 16-bit destination by one, leaving the value 03H in the register R1. In the second example, the statement "INCW @R1" uses Indirect Register (IR) addressing mode to increment the contents of the general register 03H from 0FFH to 00H and the register 02H from 0FH to 10H.

NOTE: A system malfunction may occur if you use a Zero (Z) flag (FLAGS.6) result together with an INCW instruction. To avoid this problem, it is recommended to use the INCW instruction as shown in the following example:

```
LOOP:   INCW    RR0
        LD      R2,R1
        OR      R2,R0
        JR      NZ,LOOP
```

IRET — Interrupt Return

IRET IRET (Normal) RET (Fast)

Operation:

IRET (Normal):
FLAGS ← @SP
SP ← SP + 1
PC ← @SP
SP ← SP + 2
SYM(0) ← 1

RET (Fast):
PC ↔ IP
FLAGS ← FLAGS'
FIS ← 0

This instruction is used at the end of an interrupt service routine. It restores the flag register and the program counter. It also re-enables global interrupts. A "normal IRET" is executed only if the fast interrupt status bit (FIS, bit one of the FLAGS register, 0D5H) is cleared (= "0"). If a fast interrupt occurred, IRET clears the FIS bit that was set at the beginning of the service routine.

Flags: All flags are restored to their original settings (that is, the settings before the interrupt occurred).

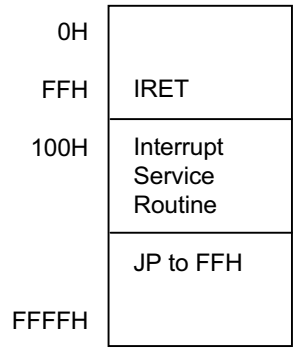
Format:

IRET (Normal)	**Bytes**	**Cycles**	**Opcode (Hex)**
opc	1	12	BF

IRET (Fast)	Bytes	Cycles	Opcode (Hex)
opc	1	6	BF

Example: In the figure below, the instruction pointer is initially loaded with 100H in the main program before interrupt are enabled. When an interrupt occurs, the program counter and the instruction pointer are swapped. This causes the PC to jump to the address 100H and the IP to keep the return address. The last instruction in the service routine is normally a jump to IRET at the address FFH.

This loads the instruction pointer with 100H "again" and causes the program counter to jump back to the main program. Now, the next interrupt can occur and the IP is still correct at 100H.



NOTE: In the fast interrupt example above, if the last instruction is not a jump to IRET, you must pay attention to the order of the last tow instruction. The IRET cannot be immediately proceeded by an instruction which clears the interrupt status (as with a reset of the IPR register).

JP — JUMP

JP cc,dst (Conditional)

JP dst (Unconditional)

Operation: If cc is true, PC ← dst

The conditional JUMP instruction transfers program control to the destination address if the condition specified by the condition code (cc) is true, otherwise, the instruction following the JP instruction is executed. The unconditional JP simply replaces the contents of the PC with the contents of the specified register pair. Control then passes to the statement addressed by the PC.

Flags: No flags are affected.

Format: (1)

(2)		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
cc | opc	dst	3	8	ccD cc = 0 to F	DA
opc	dst	2	8	30	IRR

NOTES:

1. The 3-byte format is used for a conditional jump and the 2-byte format for an unconditional jump.
2. In the first byte of the 3-byte instruction format (conditional jump), the condition code and the OPCODE are both four bits.

Examples: Given: The carry flag (C) = "1", register 00 = 01H, and register 01 = 20H:Secs

```
JP  C,LABEL_W      →    LABEL_W = 1000H, PC = 1000H
JP  @00H           →    PC = 0120H
```

The first example shows a conditional JP. Assuming that the carry flag is set to "1", the statement "JP C,LABEL_W" replaces the contents of the PC with the value 1000H and transfers control to that location. Had the carry flag not been set, control would then have passed to the statement immediately following the JP instruction.

The second example shows an unconditional JP. The statement "JP @00" replaces the contents of the PC with the contents of the register pair 00H and 01H, leaving the value 0120H.

JR — Jump Relative

JR cc,dst

Operation: If cc is true, PC ← PC + dst

If the condition specified by the condition code (cc) is true, the relative address is added to the program counter and control passes to the statement whose address is now in the program counter, otherwise, the instruction following the JR instruction is executed. (See the list of condition codes at the beginning of this chapter).

The range of the relative address is +127, –128, and the original value of the program counter is taken to be the address of the first instruction byte following the JR statement.

Flags: No flags are affected.

Format:

(note)		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
cc | opc	dst	2	6	ccB	RA
				cc = 0 to F	

NOTE: In the first byte of the two-byte instruction format, the condition code and the opcode are each four bits in length.

Example: Given: The carry flag = "1" and LABEL_X = 1FF7H:

JR C,LABEL_X → PC = 1FF7H

If the carry flag is set (that is, if the condition code is “true”), the statement "JR C,LABEL_X" will pass control to the statement whose address is currently in the program counter. Otherwise, the program instruction following the JR will be executed.

LD — LOAD

LD dst,src

Operation: dst ← src

The contents of the source are loaded into the destination. The source's contents are unaffected.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
dst | opc	src		2	4	rC	r	IM
				4	r8	r	R
src | opc	dst		2	4	r9 r = 0 to F	R	r
opc	dst | src		2	4	C7	r	Ir
				4	D7	Ir	r
opc	src	dst	3	6	E4	R	R
				6	E5	R	IR
opc	dst	src	3	6	E6	R	IM
				6	D6	IR	IM
opc	src	dst	3	6	F5	IR	R
opc	dst | src	x	3	6	87	r	x [r]
opc	src | dst	x	3	6	97	x [r]	r

LD — Load

LD (Continued)

Examples: Given: R0 = 01H, R1 = 0AH, register 00H = 01H, register 01H = 20H, register 02H = 02H, LOOP = 30H, and register 3AH = 0FFH:

LD R0,#10H	→	R0 = 10H
LD R0,01H	→	R0 = 20H, register 01H = 20H
LD 01H,R0	→	Register 01H = 01H, R0 = 01H
LD R1,@R0	→	R1 = 20H, R0 = 01H
LD @R0,R1	→	R0 = 01H, R1 = 0AH, register 01H = 0AH
LD 00H,01H	→	Register 00H = 20H, register 01H = 20H
LD 02H,@00H	→	Register 02H = 20H, register 00H = 01H
LD 00H,#0AH	→	Register 00H = 0AH
LD @00H,#10H	→	Register 00H = 01H, register 01H = 10H
LD @00H,02H	→	Register 00H = 01H, register 01H = 02, register 02H = 02H
LD R0,#LOOP[R1]	→	R0 = 0FFH, R1 = 0AH
LD #LOOP[R0],R1	→	Register 31H = 0AH, R0 = 01H, R1 = 0AH

LDB — Load Bit

LDB dst,src.b

LDB dst.b,src

Operation: dst(0) ← src(b)
or
dst(b) ← src(0)

The specified bit of the source is loaded into bit zero (LSB) of the destination, or bit zero of the source is loaded into the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | b | 0	src	3	6	47	r0	Rb
opc	src | b | 1	dst	3	6	47	Rb	r0

NOTE: In the second byte of the instruction format, the destination (or the source) address is four bits, the bit address "b" is three bits, and the LSB address value is one bit in length.

Examples: Given: R0 = 06H and general register 00H = 05H:

```
LDB     R0,00H.2    →    R0 = 07H, register 00H = 05H
LDB     00H.0,R0    →    R0 = 06H, register 00H = 04H
```

In the first example, the destination working register R0 contains the value 06H and the source general register 00H the value 05H. The statement "LD R0,00H.2" loads the bit two value of the 00H register into bit zero of the R0 register, leaving the value 07H in the register R0.

In the second example, 00H is the destination register. The statement "LD 00H.0,R0" loads bit zero of the register R0 to the specified bit (bit zero) of the destination register, leaving 04H in the general register 00H.

LDC/LDE — Load Memory

LDC dst,src

LDE dst,src

Operation: dst ← src

This instruction loads a byte from program or data memory into a working register or vice-versa. The source values are unaffected. LDC refers to program memory and LDE to data memory. The assembler makes "Irr" or "rr" values an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

					Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
1.	opc	dst | src			2	10	C3	r	Irr
2.	opc	src | dst			2	10	D3	Irr	r
3.	opc	dst | src	XS		3	12	E7	r	XS [rr]
4.	opc	src | dst	XS		3	12	F7	XS [rr]	r
5.	opc	dst | src	XL_L	XL_H	4	14	A7	r	XL [rr]
6.	opc	src | dst	XL_L	XL_H	4	14	B7	XL [rr]	r
7.	opc	dst | 0000	DA_L	DA_H	4	14	A7	r	DA
8.	opc	src | 0000	DA_L	DA_H	4	14	B7	DA	r
9.	opc	dst | 0001	DA_L	DA_H	4	14	A7	r	DA
10.	opc	src | 0001	DA_L	DA_H	4	14	B7	DA	r

NOTES:

1. The source (src) or the working register pair [rr] for formats 5 and 6 cannot use the register pair 0–1.
2. For the formats 3 and 4, the destination "XS [rr]" and the source address "XS [rr]" are both one byte.
3. For the formats 5 and 6, the destination "XL [rr] and the source address "XL [rr]" are both two bytes.
4. The DA and the r source values for the formats 7 and 8 are used to address program memory. The second set of values, used in the formats 9 and 10, are used to address data memory.
5. LDE instruction can be used to read/write the data of 64-Kbyte data memory.

LDC/LDE — Load Memory

LDC/LDE (Continued)

Examples: Given: R0 = 11H, R1 = 34H, R2 = 01H, R3 = 04H; Program memory locations 0103H = 4FH, 0104H = 1A, 0105H = 6DH, and 1104H = 88H.
External data memory locations 0103H = 5FH, 0104H = 2AH, 0105H = 7DH, and 1104H = 98H:

```
LDC     R0,@RR2             ; R0 ← contents of program memory location 0104H;
                            ; R0 = 1AH, R2 = 01H, R3 = 04H
LDE     R0,@RR2             ; R0 ← contents of external data memory location
                              0104H;
                            ; R0 = 2AH, R2 = 01H, R3 = 04H
LDC     @RR2,R0             ; 11H (contents of R0) is loaded into program memory
                            ; location 0104H (RR2); R0, R2, R3 → no change
LDE     @RR2,R0             ; 11H (contents of R0) is loaded into external data
                              memory
                            ; location 0104H (RR2); R0, R2, R3 → no change
LDC     R0,#01H[RR2]        ; R0 ← contents of program memory location 0105H
                            ; (01H + RR2); R0 = 6DH, R2 = 01H, R3 = 04H
LDE     R0,#01H[RR2]        ; R0 ← contents of external data memory location
                              0105H
                            ; (01H + RR2); R0 = 7DH, R2 = 01H, R3 = 04H
LDC     #01H[RR2],R0        ; 11H (contents of R0) is loaded into program memory
                              location
                            ; 0105H (01H + 0104H)
LDE     #01H[RR2],R0        ; 11H (contents of R0) is loaded into external data
                              memory
                            ; location 0105H (01H + 0104H)
LDC     R0,#1000H[RR2]      ; R0 ← contents of program memory location 1104H
                            ; (1000H + 0104H); R0 = 88H, R2 = 01H, R3 = 04H
LDE     R0,#1000H[RR2]      ; R0 ← contents of external data memory location
                              1104H
                            ; (1000H + 0104H); R0 = 98H, R2 = 01H, R3 = 04H
LDC     R0,1104H            ; R0 ← contents of program memory location 1104H
                            ; R0 = 88H
LDE     R0,1104H            ; R0 ← contents of external data memory location
                              1104H;
                            ; R0 = 98H
LDC     1105H,R0            ; 11H (contents of R0) is loaded into program memory
                              location
                            ; 1105H; (1105H) ← 11H
LDE     1105H,R0            ; 11H (contents of R0) is loaded into external data
                              memory
                            ; location 1105H; (1105H) ← 11H
```

NOTE: The LDC and the LDE instructions are not supported by masked ROM type devices.

LDCD/LDED — Load Memory and Decrement

LDCD dst,src

LDED dst,src

Operation: dst ← src
rr ← rr – 1

These instructions are used for user stacks or block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair. The contents of the source location are loaded into the destination location. The memory address is then decremented. The contents of the source are unaffected.

LDCD refers to program memory and LDED refers to external data memory. The assembler makes "Irr" an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src	2	10	E2	r	Irr

Examples: Given: R6 = 10H, R7 = 33H, R8 = 12H, program memory location 1033H = 0CDH, and external data memory location 1033H = 0DDH:

```
LDCD    R8,@RR6     ; 0CDH (contents of program memory location 1033H) is loaded
                    ; into R8 and RR6 is decremented by one;
                    ; R8 = 0CDH, R6 = 10H, R7 = 32H (RR6 ← RR6 – 1)
LDED    R8,@RR6     ; 0DDH (contents of data memory location 1033H) is loaded
                    ; into R8 and RR6 is decremented by one
                    (RR6 ← RR6 – 1);
                    ; R8 = 0DDH, R6 = 10H, R7 = 32H
```

NOTE: LDED instruction can be used to read/write the data of 64-Kbyte data memory.

LDCI/LDEI — Load Memory and Increment

LDCI dst,src

LDEI dst,src

Operation: dst ← src
rr ← rr + 1

These instructions are used for user stacks or block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair. The contents of the source location are loaded into the destination location. The memory address is then incremented automatically. The contents of the source are unaffected.
LDCI refers to program memory and LDEI refers to external data memory. The assembler makes "Irr" an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc | dst | src	2	10	E3	r	Irr

Examples: Given: R6 = 10H, R7 = 33H, R8 = 12H, program memory locations 1033H = 0CDH and 1034H = 0C5H; external data memory locations 1033H = 0DDH and 1034H = 0D5H:

```
LDCI    R8,@RR6     ; 0CDH (contents of program memory location 1033H) is loaded
                    ; into R8 and RR6 is incremented by one (RR6 ← RR6 + 1);
                    ; R8 = 0CDH, R6 = 10H, R7 = 34H
LDEI    R8,@RR6     ; 0DDH (contents of data memory location 1033H) is loaded
                    ; into R8 and RR6 is incremented by one (RR6 ← RR6 + 1);
                    ; R8 = 0DDH, R6 = 10H, R7 = 34H
```

NOTE: LDEI instruction can be used to read/write the data of 64-Kbyte data memory.

`

LDCPD/LDEPD — Load Memory with Pre-Decrement

LDCPD dst,src

LDEPD dst,src

Operation: rr ← rr – 1
dst ← src

These instructions are used for block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair and is first decremented. The contents of the source location are then loaded into the destination location. The contents of the source are unaffected.

LDCPD refers to program memory and LDEPD refers to external data memory. The assembler makes "Irr" an even number for program memory and an odd number for external data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src | dst	2	14	F2	Irr	r

Examples: Given: R0 = 77H, R6 = 30H, and R7 = 00H:

```
LDCPD   @RR6,R0     ; (RR6 ← RR6 – 1)
                    ; 77H (the contents of R0) is loaded into program memory
                    ; location 2FFFH (3000H – 1H);
                    ; R0 = 77H, R6 = 2FH, R7 = 0FFH
LDEPD   @RR6,R0     ; (RR6 ← RR6 – 1)
                    ; 77H (the contents of R0) is loaded into external data
memory
                    ; location 2FFFH (3000H – 1H);
```

NOTE: LDEPD instruction can be used to read/write the data of 64-Kbyte data memory.

LDCPI/LDEPI — Load Memory with Pre-Increment

LDCPI dst,src

LDEPI dst,src

Operation: rr ← rr + 1
dst ← src

These instructions are used for block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair and is first incremented. The contents of the source location are loaded into the destination location. The contents of the source are unaffected.

LDCPI refers to program memory and LDEPI refers to external data memory. The assembler makes "Irr" an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	src | dst	2	14	F3	Irr	r

Examples: Given: R0 = 7FH, R6 = 21H, and R7 = 0FFH:

```
LDCPI   @RR6,R0     ; (RR6 ← bRR6 + 1)
                    ; 7FH (the contents of R0) is loaded into program memory
                    ; location 2200H (21FFH + 1H);
                    ; R0 = 7FH, R6 = 22H, R7 = 00H
LDEPI   @RR6,R0     ; (RR6 ← bRR6 + 1)
                    ; 7FH (the contents of R0) is loaded into external data
memory
                    ; location 2200H (21FFH + 1H);
                    ; R0 = 7FH, R6 = 22H, R7 = 00H
```

NOTE: LDEPI instruction can be used to read/write the data of 64-Kbyte data memory.

LDW — Load Word

LDW dst,src

Operation: dst ← src

The contents of the source (a word) are loaded into the destination. The contents of the source are unaffected.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc | src | dst	3	8	C4	RR	RR
		8	C5	RR	IR
opc | dst | src	4	8	C6	RR	IML

Examples: Given: R4 = 06H, R5 = 1CH, R6 = 05H, R7 = 02H, register 00H = 1AH, register 01H = 02H, register 02H = 03H,and register 03H = 0FH

```
LDW     RR6,RR4     →    R6 = 06H, R7 = 1CH, R4 = 06H, R5 = 1CH
LDW     00H,02H     →    Register 00H = 03H, register 01H = 0FH,
                         register 02H = 03H, register 03H = 0FH
LDW     RR2,@R7     →    R2 = 03H, R3 = 0FH,
LDW     04H,@01H    →    Register 04H = 03H, register 05H = 0FH
LDW     RR6,#1234H  →    R6 = 12H, R7 = 34H
LDW     02H,#0FEDH  →    Register 02H = 0FH, register 03H = 0EDH
```

In the second example, please note that the statement "LDW 00H,02H" loads the contents of the source word 02H and 03H into the destination word 00H and 01H. This leaves the value 03H in the general register 00H and the value 0FH in the register 01H.

Other examples show how to use the LDW instruction with various addressing modes and formats.

MULT — Multiply (Unsigned)

MULT dst,src

Operation: dst ← dst × src

The 8-bit destination operand (the even numbered register of the register pair) is multiplied by the source operand (8 bits) and the product (16 bits) is stored in the register pair specified by the destination address. Both operands are treated as unsigned integers.

Flags:

C: Set if the result is > 255; cleared otherwise.

Z: Set if the result is "0"; cleared otherwise.

S: Set if MSB of the result is a "1"; cleared otherwise.

V: Cleared.

D: Unaffected.

H: Unaffected.

Format:

opc	src	dst

Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
3	22	84	RR	R
	22	85	RR	IR
	22	86	RR	IM

Examples: Given: Register 00H = 20H, register 01H = 03H, register 02H = 09H, register 03H = 06H:

MULT	00H, 02H	→	Register 00H = 01H, register 01H = 20H, register 02H = 09H
MULT	00H, @01H	→	Register 00H = 00H, register 01H = 0C0H
MULT	00H, #30H	→	Register 00H = 06H, register 01H = 00H

In the first example, the statement "MULT 00H,02H" multiplies the 8-bit destination operand (in the register 00H of the register pair 00H, 01H) by the source register 02H operand (09H). The 16-bit product, 0120H, is stored in the register pair 00H, 01H.

NEXT — Next

NEXT

Operation: PC ← @IP
IP ← IP + 2

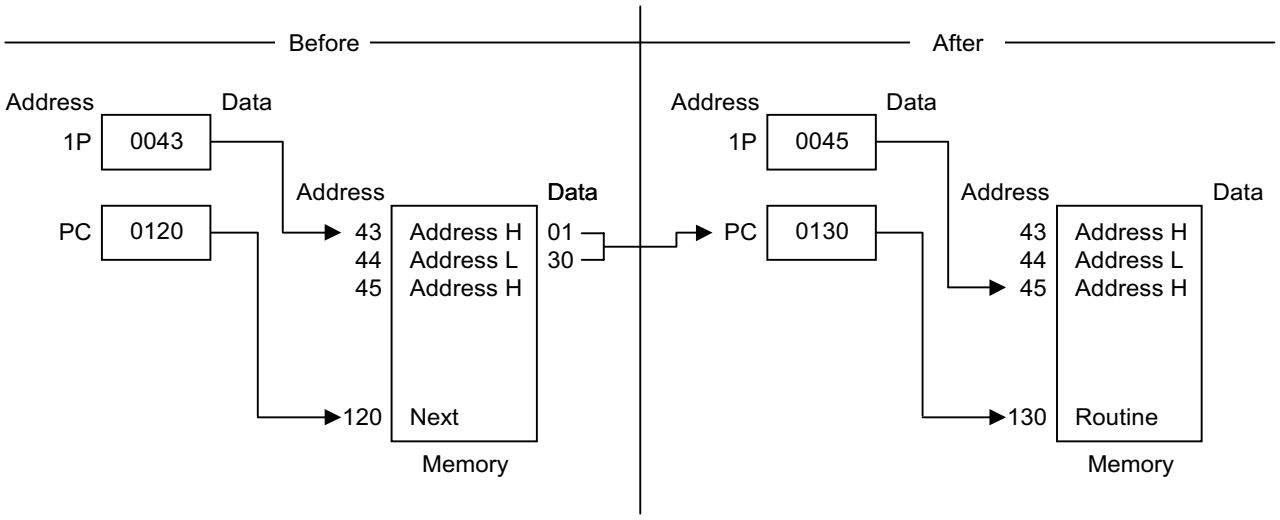
The NEXT instruction is useful when implementing threaded-code languages. The program memory word that is pointed to by the instruction pointer is loaded into the program counter. The instruction pointer is then incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	10	0F

Example: The following diagram shows an example of how to use the NEXT instruction.



NOP — No Operation

NOP

Operation: No action is performed when the CPU executes this instruction. Typically, one or more NOPs are executed in sequence in order to affect a timing delay of variable duration.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	FF

Example: When the instruction NOP is executed in a program, no operation occurs. Instead, there happens a delay in instruction execution time which is of approximately one machine cycle per each **NOP** instruction encountered.

OR — Logical OR

OR dst,src

Operation: dst ← dst OR src

The source operand is logically ORed with the destination operand and the result is stored in the destination. The contents of the source are unaffected. The OR operation results in a "1" being stored whenever either of the corresponding bits in the two operands is a "1", otherwise, a "0" is stored.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Always cleared to "0".

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst | src		2	4	42	r	r
				6	43	r	lr
opc	src	dst	3	6	44	R	R
				6	45	R	IR
opc	dst	src	3	6	46	R	IM

Examples: Given: R0 = 15H, R1 = 2AH, R2 = 01H, register 00H = 08H, register 01H = 37H, and register 08H = 8AH

OR	R0,R1	→	R0 = 3FH, R1 = 2AH
OR	R0,@R2	→	R0 = 37H, R2 = 01H, register 01H = 37H
OR	00H,01H	→	Register 00H = 3FH, register 01H = 37H
OR	01H,@00H	→	Register 00H = 08H, register 01H = 0BFH
OR	00H,#02H	→	Register 00H = 0AH

In the first example, if the working register R0 contains the value 15H and the register R1 the value 2AH, the statement "OR R0,R1" logical-ORs the R0 and R1 register contents and stores the result (3FH) in the destination register R0.

Other examples show the use of the logical OR instruction with various addressing modes and formats.

POP — Pop from Stack

POP dst

Operation: dst ← @SP
SP ← SP + 1

The contents of the location addressed by the stack pointer are loaded into the destination. The stack pointer is then incremented by one.

Flags: No flags are affected.

Format:

opc	dst

Bytes	Cycles	Opcode (Hex)	Addr Mode dst
2	8	50	R
	8	51	IR

Examples: Given: Register 00H = 01H, register 01H = 1BH, SPH (0D8H) = 00H, SPL (0D9H) = 0FBH, and stack register 0FBH = 55H:

```
POP   00H    →   Register 00H = 55H, SP = 00FCH
POP   @00H   →   Register 00H = 01H, register 01H = 55H, SP = 00FCH
```

In the first example, the general register 00H contains the value 01H. The statement "POP 00H" loads the contents of the location 00FBH (55H) into the destination register 00H and then increments the stack pointer by one. The register 00H then contains the value 55H and the SP points to the location 00FCH.

POPUD — Pop User Stack (Decrementing)

POPUD dst,src

Operation: dst ← src
IR ← IR – 1

This instruction is used for user-defined stacks in the register file. The contents of the register file location addressed by the user stack pointer are loaded into the destination. The user stack pointer is then decremented.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	src	dst	3	8	92	R	IR

Example: Given: Register 00H = 42H (user stack pointer register), register 42H = 6FH, and register 02H = 70H:

POPUD 02H,@00H → Register 00H = 41H, register 02H = 6FH, register 42H = 6FH

02H If the general register 00H contains the value 42H and the register 42H the value 6FH, the statement "POPUD 02H,@00H" loads the contents of the register 42H into the destination register. The user stack pointer is then decremented by one, leaving the value 41H.

POPUI — Pop User Stack (Incrementing)

POPUI dst,src

Operation: dst ← src
IR ← IR + 1

The POPUI instruction is used for user-defined stacks in the register file. The contents of the register file location addressed by the user stack pointer are loaded into the destination. The user stack pointer is then incremented.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	src	dst	3	8	93	R	IR

Example: Given: Register 00H = 01H and register 01H = 70H:

POPUI 02H,@00H → Register 00H = 02H, register 01H = 70H, register 02H = 70H

If the general register 00H contains the value 01H and the register 01H the value 70H, the statement "POPUI 02H,@00H" loads the value 70H into the destination general register 02H. The user stack pointer (the register 00H) is then incremented by one, changing its value from 01H to 02H.

PUSH — Push to Stack

PUSH src

Operation: SP ← SP – 1
@SP ← src

A PUSH instruction decrements the stack pointer value and loads the contents of the source (src) into the location addressed by the decremented stack pointer. The operation then adds the new value to the top of the stack.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	src	2	8 (internal clock)	70	R
			8 (external clock)		
			8 (internal clock)		
			8 (external clock)	71	IR

Examples: Given: Register 40H = 4FH, register 4FH = 0AAH, SPH = 00H, and SPL = 00H:

PUSH 40H → Register 40H = 4FH, stack register 0FFH = 4FH, SPH = 0FFH, SPL = 0FFH

PUSH @40H → Register 40H = 4FH, register 4FH = 0AAH, stack register 0FFH = 0AAH, SPH = 0FFH, SPL = 0FFH

In the first example, if the stack pointer contains the value 0000H, and the general register 40H the value 4FH, the statement "PUSH 40H" decrements the stack pointer from 0000 to 0FFFFH. It then loads the contents of the register 40H into the location 0FFFFH and adds this new value to the top of the stack.

PUSHUD — Push User Stack (Decrementing)

PUSHUD dst,src

Operation: IR ← IR – 1
dst ← src

This instruction is used to address user-defined stacks in the register file. PUSHUD decrements the user stack pointer and loads the contents of the source into the register addressed by the decremented stack pointer.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	dst	src	3	8	82	IR	R

Example: Given: Register 00H = 03H, register 01H = 05H, and register 02H = 1AH:

PUSHUD @00H,01H → Register 00H = 02H, register 01H = 05H, register 02H = 05H

If the user stack pointer (the register 00H, for example) contains the value 03H, the statement "PUSHUD @00H,01H" decrements the user stack pointer by one, leaving the value 02H. The 01H register value, 05H, is then loaded into the register addressed by the decremented user stack pointer.

PUSHUI — Push User Stack (Incrementing)

PUSHUI dst,src

Operation: IR ← IR + 1
dst ← src

This instruction is used for user-defined stacks in the register file. PUSHUI increments the user stack pointer and then loads the contents of the source into the register location addressed by the incremented user stack pointer.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst	src	3	8	83	IR	R

Example: Given: Register 00H = 03H, register 01H = 05H, and register 04H = 2AH:

PUSHUI @00H,01H → Register 00H = 04H, register 01H = 05H, register 04H = 05H

If the user stack pointer (the register 00H, for example) contains the value 03H, the statement "PUSHUI @00H,01H" increments the user stack pointer by one, leaving the value 04H. The 01H register value, 05H, is then loaded into the location addressed by the incremented user stack pointer.

RCF — Reset Carry Flag

RCF RCF

Operation: C ← 0

The carry flag is cleared to logic zero, regardless of its previous value.

Flags: **C:** Cleared to "0".

No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	CF

Example: Given: C = "1" or "0":

The instruction RCF clears the carry flag (C) to logic zero.

RET — Return

RET

Operation: PC ← @SP
SP ← SP + 2

The RET instruction is normally used to return to the previously executed procedure at the end of the procedure entered by a CALL instruction. The contents of the location addressed by the stack pointer are popped into the program counter. The next statement to be executed is the one that is addressed by the new program counter value.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	10	AF

Example: Given: SP = 00FCH, (SP) = 101AH, and PC = 1234:

RET → PC = 101AH, SP = 00FEH

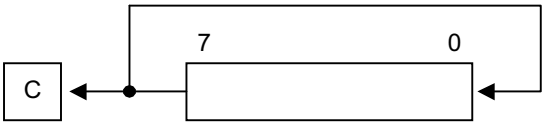
The RET instruction pops the contents of the stack pointer location 00FCH (10H) into the high byte of the program counter. The stack pointer then pops the value in the location 00FEH (1AH) into the PC's low byte and the instruction at the location 101AH is executed. The stack pointer now points to the memory location 00FEH.

RL — Rotate Left

RL dst

Operation: C ← dst (7)
dst (0) ← dst (7)
dst (n + 1) ← dst (n), n = 0–6

The contents of the destination operand are rotated left one bit position. The initial value of bit 7 is moved to the bit zero (LSB) position and also replaces the carry flag, as shown in the figure below.



Flags:
C: Set if the bit rotated from the most significant bit position (bit 7) was "1".
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc | dst	2	4	90	R
		4	91	IR

Examples: Given: Register 00H = 0AAH, register 01H = 02H and register 02H = 17H:

RL 00H → Register 00H = 55H, C = "1"
RL @01H → Register 01H = 02H, register 02H = 2EH, C = "0"

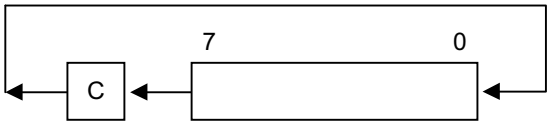
In the first example, if the general register 00H contains the value 0AAH (10101010B), the statement "RL 00H" rotates the 0AAH value left one bit position, leaving the new value 55H (01010101B) and setting the carry (C) and the overflow (V) flags.

RLC — Rotate Left through Carry

RLC dst

Operation: dst (0) ← C
C ← dst (7)
dst (n + 1) ← dst (n), n = 0–6

The contents of the destination operand with the carry flag are rotated left one bit position. The initial value of bit 7 replaces the carry flag (C), and the initial value of the carry flag replaces bit zero.



Flags:
C: Set if the bit rotated from the most significant bit position (bit 7) was "1".
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the sign of the destination is changed during the rotation; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc dst	2	4	10	R
		4	11	IR

Examples: Given: Register 00H = 0AAH, register 01H = 02H, and register 02H = 17H, C = "0":

```
RLC   00H    →   Register 00H = 54H, C = "1"
RLC   @01H   →   Register 01H = 02H, register 02H = 2EH, C = "0"
```

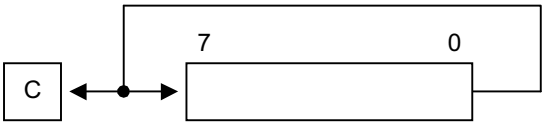
In the first example, if the general register 00H has the value 0AAH (10101010B), the statement "RLC 00H" rotates 0AAH one bit position to the left. The initial value of bit 7 sets the carry flag and the initial value of the C flag replaces bit zero of the register 00H, leaving the value 55H (01010101B). The MSB of the register 00H resets the carry flag to "1" and sets the overflow flag.

RR — Rotate Right

RR dst

Operation: C ← dst (0)
dst (7) ← dst (0)
dst (n) ← dst (n + 1), n = 0–6

The contents of the destination operand are rotated right one bit position. The initial value of bit zero (LSB) is moved to bit 7 (MSB) and also replaces the carry flag (C).



Flags:
C: Set if the bit rotated from the least significant bit position (bit zero) was "1".
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the sign of the destination is changed during the rotation; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc dst	2	4	E0	R
		4	E1	IR

Examples: Given: Register 00H = 31H, register 01H = 02H, and register 02H = 17H:

```
RR    00H    →    Register 00H = 98H, C = "1"
RR    @01H   →    Register 01H = 02H, register 02H = 8BH, C = "1"
```

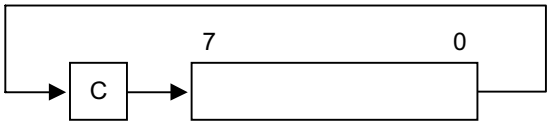
In the first example, if the general register 00H contains the value 31H (00110001B), the statement "RR 00H" rotates this value one bit position to the right. The initial value of bit zero is moved to bit 7, leaving the new value 98H (10011000B) in the destination register. The initial bit zero also resets the C flag to "1" and the sign flag and the overflow flag are also set to "1".

RRC — Rotate Right through Carry

RRC dst

Operation: dst (7) ← C
C ← dst (0)
dst (n) ← dst (n + 1), n = 0–6

The contents of the destination operand and the carry flag are rotated right one bit position. The initial value of bit zero (LSB) replaces the carry flag, and the initial value of the carry flag replaces bit 7 (MSB).



Flags:
C: Set if the bit rotated from the least significant bit position (bit zero) was "1".
Z: Set if the result is "0" cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Set if arithmetic overflow occurred, that is, if the sign of the destination is changed during the rotation; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc dst	2	4	C0	R
		4	C1	IR

Examples: Given: Register 00H = 55H, register 01H = 02H, register 02H = 17H, and C = "0":

```
RRC   00H    →   Register 00H = 2AH, C = "1"
RRC   @01H   →   Register 01H = 02H, register 02H = 0BH, C = "1"
```

In the first example, if the general register 00H contains the value 55H (01010101B), the statement "RRC 00H" rotates this value one bit position to the right. The initial value of bit zero ("1") replaces the carry flag and the initial value of the C flag ("1") replaces bit 7. This leaves the new value 2AH (00101010B) in the destination register 00H. The sign flag and the overflow flag are both cleared to "0".

SB0 — Select Bank 0

SB0

Operation: BANK ← 0

The SB0 instruction clears the bank address flag in the FLAGS register (FLAGS.0) to logic zero, selecting the bank 0 register addressing in the set 1 area of the register file.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	4F

Example: The statement **SB0** clears FLAGS.0 to "0", selecting the bank 0 register addressing.

SB1 — Select Bank 1

SB1

Operation: BANK ← 1

The SB1 instruction sets the bank address flag in the FLAGS register (FLAGS.0) to logic one, selecting the bank 1 register addressing in the set 1 area of the register file.

NOTE: Bank 1 is not implemented in some KS88-series microcontrollers.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	5F

Example: The statement **SB1** sets FLAGS.0 to “1”, selectin the bank 1 register addressing (if bank 1 is implemented in the microcontrooler’s internla register file).

SBC — Subtract with Carry

SBC dst,src

Operation: dst ← dst – src – c

The source operand, along with the current value of the carry flag, is subtracted from the destination operand and the result is stored in the destination. The contents of the source are unaffected. Subtraction is performed by adding the two's-complement of the source operand to the destination operand. In multiple precision arithmetic, this instruction permits the carry ("borrow") from the subtraction of the low-order operands to be subtracted from the subtraction of high-order operands.

Flags:

C: Set if a borrow occurred (src > dst); cleared otherwise.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result is negative; cleared otherwise.

V: Set if arithmetic overflow occurred, that is, if the operands were of opposite sign and the sign of the result is the same as the sign of the source; cleared otherwise.

D: Always set to "1".

H: Cleared if there is a carry from the most significant bit of the low-order four bits of the result; set otherwise, indicating a "borrow"

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | src		2	4	32	r	r
				6	33	r	lr
opc	src	dst	3	6	34	R	R
				6	35	R	IR
opc	dst	src	3	6	36	R	IM

Examples: Given: R1 = 10H, R2 = 03H, C = "1", register 01H = 20H, register 02H = 03H, and register 03H = 0AH:

SBC	R1,R2	→	R1 = 0CH, R2 = 03H
SBC	R1,@R2	→	R1 = 05H, R2 = 03H, register 03H = 0AH
SBC	01H,02H	→	Register 01H = 1CH, register 02H = 03H
SBC	01H,@02H	→	Register 01H = 15H, register 02H = 03H, register 03H = 0AH
SBC	01H,#8AH	→	Register 01H = 95H; C, S, and V = "1"

In the first example, if the working register R1 contains the value 10H and the register R2 the value 03H, the statement "SBC R1,R2" subtracts the source value (03H) and the C flag value ("1") from the destination (10H) and then stores the result (0CH) in the register R1.

SCF — Set Carry Flag

SCF

Operation: C ← 1

The carry flag (C) is set to logic one, regardless of its previous value.

Flags: C: Set to "1".

No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4	DF

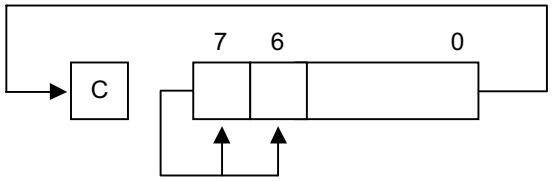
Example: The statement **SCF** sets the carry flag to “1”.

SRA — Shift Right Arithmetic

SRA dst

Operation: dst (7) ← dst (7)
C ← dst (0)
dst (n) ← dst (n + 1), n = 0–6

An arithmetic shift-right of one bit position is performed on the destination operand. Bit zero (the LSB) replaces the carry flag. The value of bit 7 (the sign bit) is unchanged and is shifted into the bit position 6.



Flags:
C: Set if the bit shifted from the LSB position (bit zero) was "1".
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Always cleared to "0".
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc	dst	2	4	D0	R
			4	D1	IR

Examples: Given: Register 00H = 9AH, register 02H = 03H, register 03H = 0BCH, and C = "1":

```
SRA     00H     →     Register 00H = 0CD, C = "0"
SRA     @02H    →     Register 02H = 03H, register 03H = 0DEH, C = "0"
```

In the first example, if the general register 00H contains the value 9AH (10011010B), the statement "SRA 00H" shifts the bit values in the register 00H right one bit position. Bit zero ("0") clears the C flag and bit 7 ("1") is then shifted into the bit 6 position (bit 7 remains unchanged). This leaves the value 0CDH (11001101B) in the destination register 00H.

SRP/SRP0/SRP1 — Set Register Pointer

SRP src

SRP0 src

SRP1 src

Operation:

If src (1) = 1 and src (0) = 0 then: RP0 (3–7) ← src (3–7)
If src (1) = 0 and src (0) = 1 then: RP1 (3–7) ← src (3–7)
If src (1) = 0 and src (0) = 0 then: RP0 (4–7) ← src (4–7),
RP0 (3) ← 0
RP1 (4–7) ← src (4–7),
RP1 (3) ← 1

The source data bits one and zero (LSB) determine whether to write one or both of the register pointers, RP0 and RP1. Bits 3–7 of the selected register pointer are written unless both register pointers are selected. RP0.3 is then cleared to logic zero and RP1.3 is set to logic one.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode src
opc	src	2	4	31	IM

Examples: The statement **SRP #40H** sets the register pointer 0 (RP0) at the location 0D6H to 40H and the register pointer 1 (RP1) at the location 0D7H to 48 H.

The statement "SRP0 #50H" would set RP0 to 50H, and the statement "SRP1 #68H" would set RP1 to 68H.

NOTE: Before execute the STOP instruction, You must set the STPCON register as “10100101b”. Otherwise the STOP instruction will not execute.

STOP — Stop Operation

STOP

Operation: The STOP instruction stops the both the CPU clock and system clock and causes the microcontroller to enter Stop mode. During Stop mode, the contents of on-chip CPU registers, peripheral registers, and I/O port control and data registers are retained. Stop mode can be released by an external reset operation or by external interrupts. For the reset operation, the RESET pin must be held to Low level until the required oscillation stabilization interval has elapsed.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst	src
opc	1	4	7F	–	–

Example: The statement **STOP** halts all microcontroller operations.

SUB — Subtract

SUB dst,src

Operation: dst ← dst – src

The source operand is subtracted from the destination operand and the result is stored in the destination. The contents of the source are unaffected. Subtraction is performed by adding the two's complement of the source operand to the destination operand.

Flags:

C: Set if a "borrow" occurred; cleared otherwise.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result is negative; cleared otherwise.

V: Set if arithmetic overflow occurred, that is, if the operands were of opposite signs and the sign of the result is of the same as the sign of the source operand; cleared otherwise.

D: Always set to "1".

H: Cleared if there is a carry from the most significant bit of the low-order four bits of the result; set otherwise indicating a “borrow”.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | src		2	4	22	r	r
				6	23	r	lr
opc	src	dst	3	6	24	R	R
				6	25	R	IR
opc	dst	src	3	6	26	R	IM

Examples: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

SUB	R1,R2	→	R1 = 0FH, R2 = 03H
SUB	R1,@R2	→	R1 = 08H, R2 = 03H
SUB	01H,02H	→	Register 01H = 1EH, register 02H = 03H
SUB	01H,@02H	→	Register 01H = 17H, register 02H = 03H
SUB	01H,#90H	→	Register 01H = 91H; C, S, and V = "1"
SUB	01H,#65H	→	Register 01H = 0BCH; C and S = "1", V = "0"

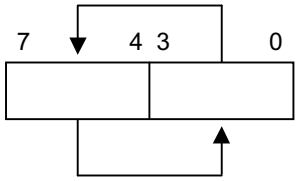
In the first example, if he working register R1 contains the value 12H and if the register R2 contains the value 03H, the statement "SUB R1,R2" subtracts the source value (03H) from the destination value (12H) and stores the result (0FH) in the destination register R1.

SWAP — Swap Nibbles

SWAP dst

Operation: dst (0 – 3) ↔ dst (4 – 7)

The contents of the lower four bits and the upper four bits of the destination operand are swapped.



Flags:

C: Undefined.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Undefined.

D: Unaffected.

H: Unaffected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr Mode dst
opc dst	2	4	F0	R
		4	F1	IR

Examples: Given: Register 00H = 3EH, register 02H = 03H, and register 03H = 0A4H:

```
SWAP    00H     →    Register 00H = 0E3H
SWAP    @02H    →    Register 02H = 03H, register 03H = 4AH
```

In the first example, if the general register 00H contains the value 3EH (00111110B), the statement "SWAP 00H" swaps the lower and the upper four bits (nibbles) in the 00H register, leaving the value 0E3H (11100011B).

TCM — Test Complement under Mask

TCM dst,src

Operation: (NOT dst) AND src

This instruction tests selected bits in the destination operand for a logic one value. The bits to be tested are specified by setting a "1" bit in the corresponding position of the source operand (mask). The TCM statement complements the destination operand, which is then ANDed with the source mask. The zero (Z) flag can then be checked to determine the result. The destination and the source operands are unaffected.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Always cleared to "0".

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | src		2	4	62	r	r
				6	63	r	lr
opc	src	dst	3	6	64	R	R
				6	65	R	IR
opc	dst	src	3	6	66	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 12H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

TCM	R0,R1	→	R0 = 0C7H, R1 = 02H, Z = "1"
TCM	R0,@R1	→	R0 = 0C7H, R1 = 02H, register 02H = 23H, Z = "0"
TCM	00H,01H	→	Register 00H = 2BH, register 01H = 02H, Z = "1"
TCM	00H,@01H	→	Register 00H = 2BH, register 01H = 02H, register 02H = 23H, Z = "1"
TCM	00H,#34	→	Register 00H = 2BH, Z = "0"

In the first example, if the working register R0 contains the value 0C7H (11000111B) and the register R1 the value 02H (00000010B), the statement "TCM R0,R1" tests bit one in the destination register for a "1" value. Because the mask value corresponds to the test bit, the Z flag is set to logic one and can be tested to determine the result of the TCM operation.

TM — Test under Mask

TM dst,src

Operation: dst AND src

This instruction tests selected bits in the destination operand for a logic zero value. The bits to be tested are specified by setting a "1" bit in the corresponding position of the source operand (mask), which is ANDed with the destination operand. The zero (Z) flag can then be checked to determine the result. The destination and the source operands are unaffected.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Always reset to "0".

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | src		2	4	72	r	r
				6	73	r	lr
opc	src	dst	3	6	74	R	R
				6	75	R	IR
opc	dst	src	3	6	76	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 18H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

TM	R0,R1	→	R0 = 0C7H, R1 = 02H, Z = "0"
TM	R0,@R1	→	R0 = 0C7H, R1 = 02H, register 02H = 23H, Z = "0"
TM	00H,01H	→	Register 00H = 2BH, register 01H = 02H, Z = "0"
TM	00H,@01H	→	Register 00H = 2BH, register 01H = 02H, register 02H = 23H, Z = "0"
TM	00H,#54H	→	Register 00H = 2BH, Z = "1"

In the first example, if the working register R0 contains the value 0C7H (11000111B) and the register R1 the value 02H (00000010B), the statement "TM R0,R1" tests bit one in the destination register for a "0" value. Because the mask value does not match the test bit, the Z flag is cleared to logic zero and can be tested to determine the result of the TM operation.

WFI — Wate for Interrupt

WFI

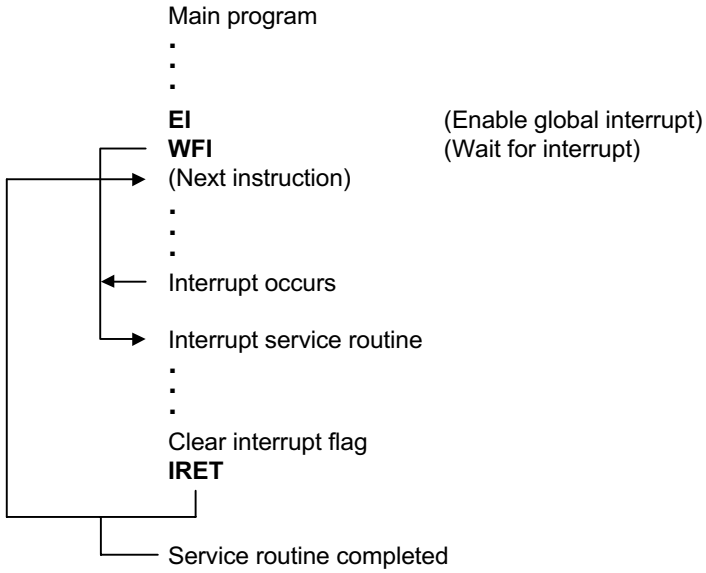
Operation: The CPU is effectively halted before an interrupt occurs, except that DMA transfers can still take place during this wait state. The WFI status can be released by an internal interrupt, including a fast interrupt.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
opc	1	4n (n = 1, 2, 3, …)	3F

Example: The following sample program structure shows the sequence of operations that follow a "WFI" statement:



XOR — Logical Exclusive OR

XOR dst,src

Operation: dst ← dst XOR src

The source operand is logically exclusive-ORed with the destination operand and the result is stored in the destination. The exclusive-OR operation results in a "1" bit being stored whenever the corresponding bits in the operands are different. Otherwise, a "0" bit is stored.

Flags:

C: Unaffected.

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Always reset to "0".

D: Unaffected.

H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode dst	Addr Mode src
opc	dst | src		2	4	B2	r	r
				6	B3	r	lr
opc	src	dst	3	6	B4	R	R
				6	B5	R	IR
opc	dst	src	3	6	B6	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 18H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

XOR	R0,R1	→	R0 = 0C5H, R1 = 02H
XOR	R0,@R1	→	R0 = 0E4H, R1 = 02H, register 02H = 23H
XOR	00H,01H	→	Register 00H = 29H, register 01H = 02H
XOR	00H,@01H	→	Register 00H = 08H, register 01H = 02H, register 02H = 23H
XOR	00H,#54H	→	Register 00H = 7FH

In the first example, if the working register R0 contains the value 0C7H and if the register R1 contains the value 02H, the statement "XOR R0,R1" logically exclusive-ORs the R1 value with the R0 value and stores the result (0C5H) in the destination register R0.

NOTES

7 CLOCK CIRCUIT

OVERVIEW

The clock frequency generation for the S3C8238/C8235/F8235 by an external crystal can range from 1 MHz to 8 MHz. The maximum CPU clock frequency is 8 MHz (mask version is 10 MHz). The X_{IN} and X_{OUT} pins connect the external oscillator or clock source to the on-chip clock circuit.

SYSTEM CLOCK CIRCUIT

The system clock circuit has the following components:

— External crystal or ceramic resonator oscillation source (or an external clock source)
— Oscillator stop and wake-up functions
— Programmable frequency divider for the CPU clock (fxx divided by 1, 2, 8, or 16)
— System clock control register, CLKCON
— Oscillator control register, OSCCON and STOP control register, STPCON

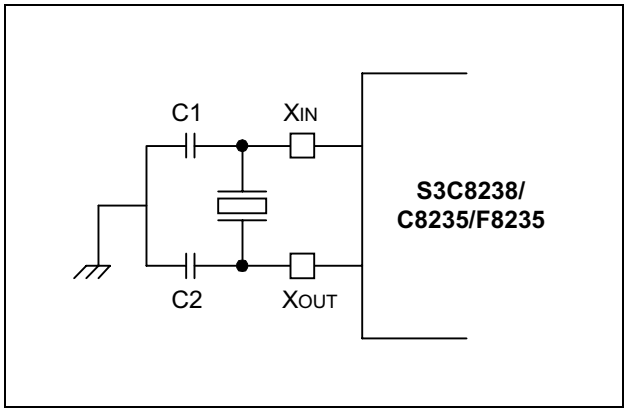


Figure 7-1. Main Oscillator Circuit (Crystal or Ceramic Oscillator)

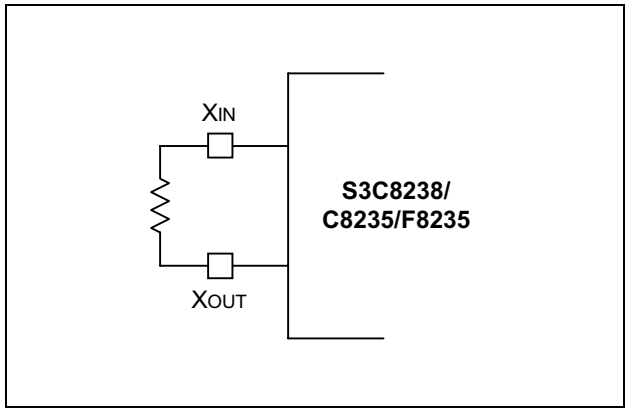

Figure 7-2. Main Oscillator Circuit (RC Oscillator)

CLOCK STATUS DURING POWER-DOWN MODES

The two power-down modes, Stop mode and Idle mode, affect the system clock as follows:

— In Stop mode, the main oscillator is halted. Stop mode is released, and the oscillator started, by a reset operation or an external interrupt (with RC delay noise filter), and can be released by internal interrupt too when the sub-system oscillator is running and watch timer is operating with sub-system clock.

— In Idle mode, the internal clock signal is gated to the CPU, but not to interrupt structure, timers and timer/counters. Idle mode is released by a reset or by an external or internal interrupt.

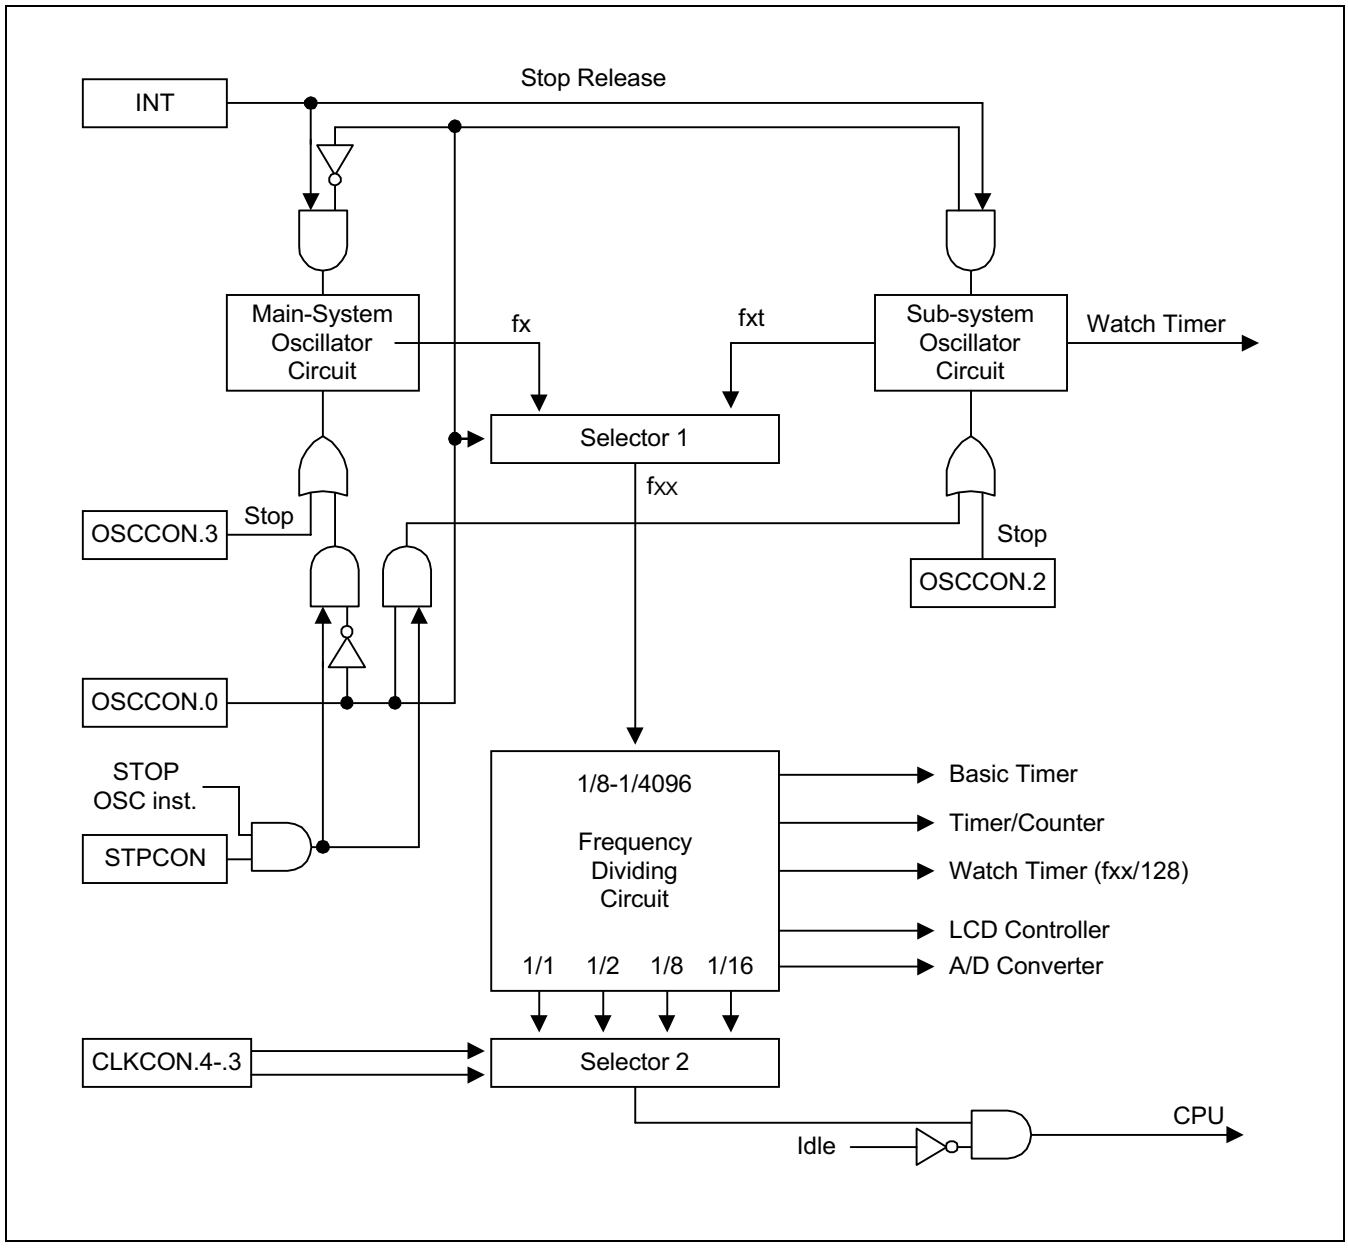

Figure 7-3. System Clock Circuit Diagram

SYSTEM CLOCK CONTROL REGISTER (CLKCON)

The system clock control register, CLKCON, is located in the bank 0 of set 1, address D4H. It is read/write addressable and has the following functions:

— Oscillator frequency divide-by value

After the main oscillator is activated, and the fxx/16 (the slowest clock speed) is selected as the CPU clock. If necessary, you can then increase the CPU clock speed to fxx/8, fxx/2, or fxx/1.

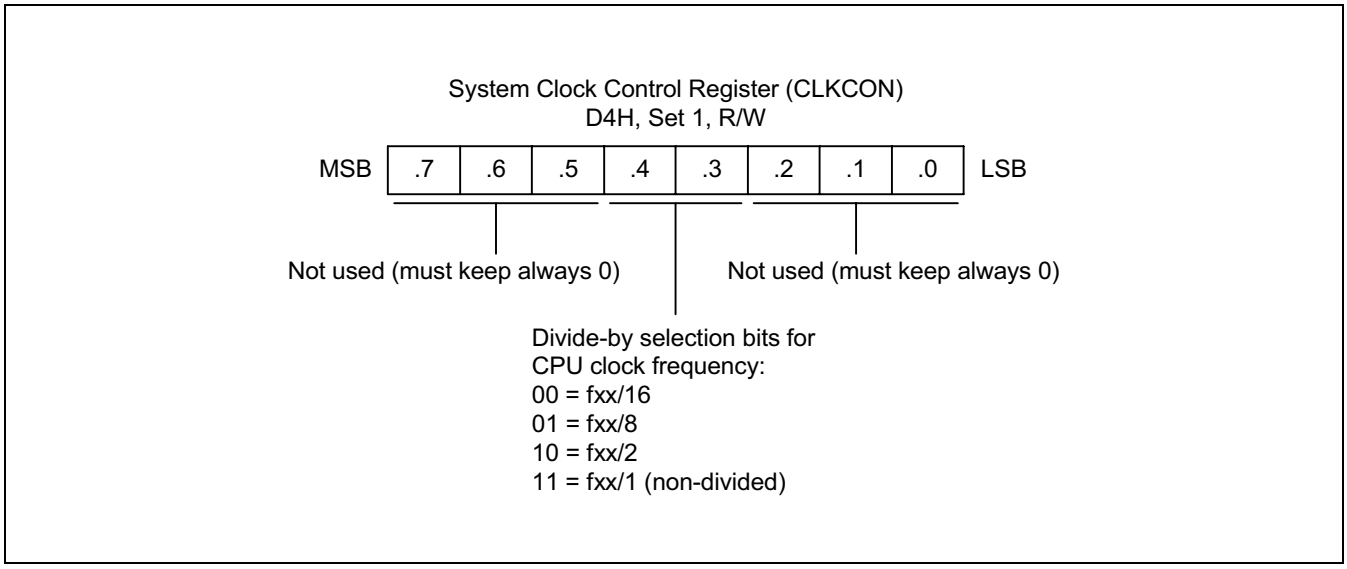

Figure 7-4. System Clock Control Register (CLKCON)

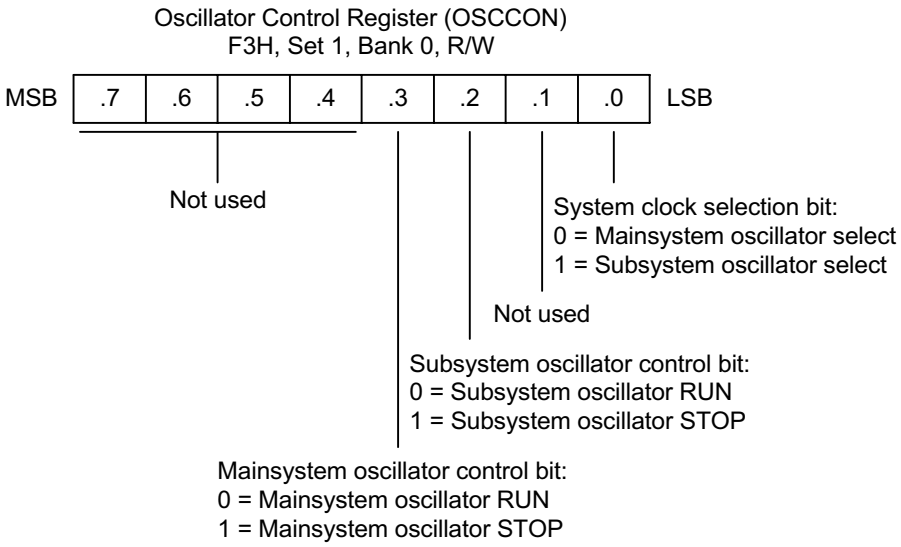
MAIN/SUBSYSTEM OSCILLATOR SELECTION

When a main oscillator is selected, users cannot stop operating of a main oscillator by handling the OSCCON register but sub oscillator can be stopped. If users intend to stop operating of a main oscillator users must use "STOP" instruction.
When a sub oscillator is selected, users must do the contrary of the above case.

In stop mode selected by the OSCCON register not by "STOP" instruction, users can release stop mode only by handling the OSCCON register not by interrupts.



NOTE: When the CPU is operated with fxt (sub-oscillation clock), it is possible to use the stop instruction but in this case before using stop instruction, ***you must select fxx/128 for basic timer counter clock input***. Then the oscillation stabilization time is 62.5 ((1/32768) x 128 x 16) ms. Here the warm-up time is from the stop release signal activates until the basic timer counter counting start. So the totaly needed oscillation stabilization time will be less than 162.5 ms.

Figure 7-5. Oscillator Control Register (OSCCON)

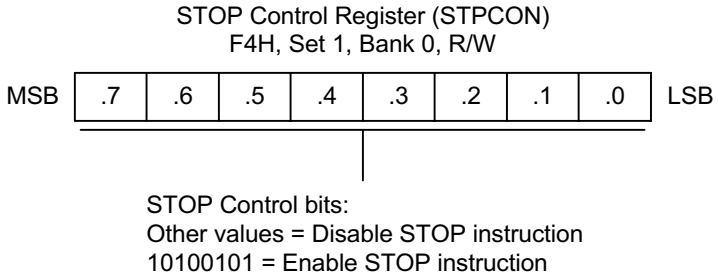


Figure 7-6. STOP Control Register (STPCON)

8 RESET and POWER-DOWN

SYSTEM RESET

OVERVIEW

During a power-on reset, the voltage at V_{DD} goes to High level and the RESET pin is forced to Low level. The RESET signal is input through a Schmitt trigger circuit where it is then synchronized with the CPU clock. This procedure brings S3C8238/C8235/F8235 into a known operating status.

To allow time for internal CPU clock oscillation to stabilize, the RESET pin must be held to Low level for a minimum time interval after the power supply comes within tolerance. The minimum required oscillation stabilization time for a reset operation is 1 millisecond.

Whenever a reset occurs during normal operation (that is, when both V_{DD} and RESET are High level), the RESET pin is forced Low and the reset operation starts. All system and peripheral control registers are then reset to their default hardware values

In summary, the following sequence of events occurs during a reset operation:

— Interrupt is disabled.

— The watchdog function (basic timer) is enabled.

— Ports 0-4 are set to input mode.

— Peripheral control and data registers are disabled and reset to their default hardware values.

— The program counter (PC) is loaded with the program reset address in the ROM, 0100H.

— When the programmed oscillation stabilization time interval has elapsed, the instruction stored in ROM location 0100H (and 0101H) is fetched and executed.

NORMAL MODE RESET OPERATION

In normal (masked ROM) mode, the Test pin is tied to V_{SS}. A reset enables access to the 16-Kbyte on-chip ROM. (The external interface is not automatically configured).

NOTE

To program the duration of the oscillation stabilization interval, you make the appropriate settings to the basic timer control register, BTCON, *before* entering Stop mode. Also, if you do not want to use the basic timer watchdog function (which causes a system reset if a basic timer counter overflow occurs), you can disable it by writing '1010B' to the upper nibble of BTCON.

HARDWARE RESET VALUES

Table 8-1, 8-2, 8-3 list the reset values for CPU and system registers, peripheral control registers, and peripheral data registers following a reset operation. The following notation is used to represent reset values:

— A "1" or a "0" shows the reset bit value as logic one or logic zero, respectively.

— An "x" means that the bit value is undefined after a reset.

— A dash ("–") means that the bit is either not used or not mapped, but read 0 is the bit value.

Table 8-1. S3C8238/C8235/F8235 Set 1 Register Values after RESET (Mask ROM Mode)

Register Name	Mnemonic	Address		Bit Values After RESET							
		Dec	Hex	7	6	5	4	3	2	1	0
LCD control register	LCON	208	D0H	0	0	0	0	0	0	0	0

POWER-DOWN MODES

STOP MODE

Stop mode is invoked by the instruction STOP (opcode 7FH). In Stop mode, the operation of the CPU and all peripherals is halted. That is, the on-chip main oscillator stops and the supply current is reduced to less than 3 μA. All system functions stop when the clock "freezes," but data stored in the internal register file is retained. Stop mode can be released in one of two ways: by a reset or by interrupts.

NOTE

Do not use stop mode if you are using an external clock source because X_{IN} input must be restricted internally to V_{SS} to reduce current leakage.

Using RESET to Release Stop Mode

Stop mode is released when the RESET signal is released and returns to high level: all system and peripheral control registers are reset to their default hardware values and the contents of all data registers are retained. A reset operation automatically selects a slow clock (1/16) because CLKCON.3 and CLKCON.4 are cleared to '00B'. After the programmed oscillation stabilization interval has elapsed, the CPU starts the system initialization routine by fetching the program instruction stored in ROM location 0100H (and 0101H).

Using an External Interrupt to Release Stop Mode

External interrupts with an RC-delay noise filter circuit can be used to release Stop mode. Which interrupt you can use to release Stop mode in a given situation depends on the microcontroller's current internal operating mode. The external interrupts in the S3C8238/C8235/F8235 interrupt structure that can be used to release Stop mode are:

— External interrupts P0.0-P0.7 (INT0-NT7)

Please note the following conditions for Stop mode release:

— If you release Stop mode using an external interrupt, the current values in system and peripheral control registers are unchanged except **STPCON register**.

— If you use an external interrupt for Stop mode release, you can also program the duration of the oscillation stabilization interval. To do this, you must make the appropriate control and clock settings *before* entering Stop mode.

— When the Stop mode is released by external interrupt, the CLKCON.4 and CLKCON.3 bit-pair setting remains unchanged and the currently selected clock value is used.

— The external interrupt is serviced when the Stop mode release occurs. Following the IRET from the service routine, the instruction immediately following the one that initiated Stop mode is executed.

Using an internal Interrupt to Release Stop Mode

Activate any enabled interrupt, causing stop mode to be released. Other things are same as using external interrupt.

How to enter into stop mode

There are two ways to enter into stop mode.

— Handling OSCCON register.

— Handling STPCON register then writing STOP instruction. (Keep the order)

IDLE MODE

Idle mode is invoked by the instruction IDLE (opcode 6FH). In idle mode, CPU operations are halted while some peripherals remain active. During idle mode, the internal clock signal is gated away from the CPU, but all peripherals timers remain active. Port pins retain the mode (input or output) they had at the time idle mode was entered.

There are two ways to release idle mode:

1. Execute a reset. All system and peripheral control registers are reset to their default values and the contents of all data registers are retained. The reset automatically selects the slow clock fxx/16 because CLKCON.4 and CLKCON.3 are cleared to '00B'. If interrupts are masked, a reset is the only way to release idle mode.
2. Activate any enabled interrupt, causing idle mode to be released. When you use an interrupt to release idle mode, the CLKCON.4 and CLKCON.3 register values remain unchanged, and the currently selected clock value is used. The interrupt is then serviced. When the return-from-interrupt (IRET) occurs, the instruction immediately following the one that initiated idle mode is executed.

9 I/O PORTS

OVERVIEW

The S3C8238/C8235/F8235 microcontroller has five bit-programmable I/O ports, P0-P4. The port 3 and port 4 are 4-bit ports and the others are 8-bit ports. This gives a total of 32 I/O pins. Each port can be flexibly configured to meet application design requirements. The CPU accesses ports by directly writing or reading port registers. No special I/O instructions are required.

Table 9-1 gives you a general overview of the S3C8238/C8235/F8235 I/O port functions.

Table 9-1. S3C8238/C8235/F8235 Port Configuration Overview

Port	Configuration Options
0	1-bit programmable I/O port. Schmitt trigger input or output mode selected by software; software assignable pull-up. P0.0-P0.7 can be used as inputs for external interrupts INT0-INT7 (with noise filter and interrupt control).
1	1-bit programmable I/O port. Normal input, AD input and output mode selected by software; for P1.0-P1.3, push-pull or open-drain output mode can be selected by software; software assignable pull-up. Alternatively P1.4-P1.7 can be used as PG0-PG3.
2	1-bit programmable I/O port. Normal input, open-drain and push-pull output with software assignable pull-up. Alternatively P2.0-P2.7 can be used as SEG12-SEG19.
3	1-bit programmable I/O port. Push-pull output and schmitt trigger input with mode selected by software. P3.0-P3.3 can alternately be used as KIN0-KIN3.
4	1-bit programmable I/O port. Push-pull output and normal input mode with software assignable pull-up. Alternatively P4 can be used asPG4-PG7.

PORT DATA REGISTERS

Table 9-2 gives you an overview of the register locations of all five S3C8238/C8235/F8235 I/O port data registers. Data registers for ports 0, 1, 2, 3, and 4 have the general format shown in Figure 9-1.

Table 9-2. Port Data Register Summary

Register Name	Mnemonic	Decimal	Hex	Location	R/W
Port 0 data register	P0	224	E0H	Set 1, Bank 0	R/W
Port 1 data register	P1	225	E1H	Set 1, Bank 0	R/W
Port 2 data register	P2	226	E2H	Set 1, Bank 0	R/W
Port 3 data register	P3	227	E3H	Set 1, Bank 0	R/W
Port 4 data register	P4	228	E4H	Set 1, Bank 0	R/W

PORT 0

Port 0 is an 8-bit I/O Port that you can use two ways:

— General-purpose I/O

— External interrupt inputs for INT0-INT7

— Alternative function

Port 0 is accessed directly by writing or reading the port 0 data register, P0 at location E0H in set 1, bank 0.

Port 0 Control Register (P0CONH, P0CONL)

Port 0 pins are configured individually by bit-pair settings in two control registers located in set 1, bank 1: P0CONL (low byte, E1H) and P0CONH (high byte, E0H).

When you select output mode, a push-pull circuit is configured. In input mode, three different selections are available:

— Schmitt trigger input with interrupt generation on falling signal edges.

— Schmitt trigger input with timer 1 capture signal.

— Schmitt trigger input with interrupt generation on falling/rising signal edges.

Port 0 Interrupt Enable and Pending Registers (P0INT, P0PND)

To process external interrupts at the port 0 pins, two additional control registers are provided: the port 0 interrupt enable register P0INT (E5H, set 1, bank 0) and the port 0 interrupt pending register P0PND (E6H, set 1, bank 0).

The port 0 interrupt pending register P0PND lets you check for interrupt pending conditions and clear the pending condition when the interrupt service routine has been initiated. The application program detects interrupt requests by polling the P0PND register at regular intervals.

When the interrupt enable bit of any port 0 pin is “1”, a rising or falling signal edge at that pin will generate an interrupt request. The corresponding P0PND bit is then automatically set to “1” and the IRQ level goes low to signal the CPU that an interrupt request is waiting. When the CPU acknowledges the interrupt request, application software must the clear the pending condition by writing a “0” to the corresponding P0PND bit.

PORT 1

Port 1 is an 8-bit I/O port with individually configurable pins. Port 1 pins are accessed directly by writing or reading the port 1 data register, P1 at location E1H in set 1, bank 0. P1.0–P1.7 can serve as inputs outputs (push pull or open-drain) or you can configure the following alternative functions:

— Low-byte pins (P1.0-P1.3): AD0-AD3

— High-byte pins (P1.4-P1.7): AD4-AD7, COM4-COM7, PG0-PG3

Port 1 Control Register (P1CONH, P1CONL)

Port 1 has two 8-bit control registers: P1CONH for P1.4–P1.7 and P1CONL for P1.0–P1.3. A reset clears the P1CONH and P1CONL registers to “00H”, configuring all pins to input mode. You use control registers settings to select input or output mode (push-pull or open drain) and enable the alternative functions.

When programming the port, please remember that any alternative peripheral I/O function you configure using the port 1 control registers must also be enabled in the associated peripheral module.

Port 1 Pull-up Resistor Enable Register (P1PUR)

Using the port 1 pull-up resistor enable register, P1PUR (E3H, set 1, bank 1), you can configure pull-up resistors to individual port 1 pins.

Figure 9-7. Port 1 Pull-up Control Register (P1PUR)

PORT 2

Port 2 is an 8-bit I/O port that can be used for general-purpose I/O and SEG12-SEG19. The pins are accessed directly by writing or reading the port 2 data register, P2 at location E2H in set 1, bank 0.

To individually configure the port 2 pins P2.0–P2.7, you make bit-pair settings in two control registers located in set 1, bank 1: P2CONL (low byte, E7H) and P2CONH (high byte, E6H).

Port 2 Control Registers (P2CONH, P2CONL)

Two 8-bit control registers are used to configure port 2 pins: P2CONL (E7H, set 1, Bank 1) for pins P2.0–P2.3 and P2CONH (E6H, set 1, Bank 1) for pins P2.4–P2.7. Each byte contains four bit-pairs and each bit-pair configures one pin of port 2.

PORT 3

Port 3 is an 4-bit I/O port with individually configurable pins. Port 3 pins are accessed directly by writing or reading the port 3 data register, P3 at location E3H in set 1, bank 0. P3.0–P3.3 can serve as inputs as push-pull outputs, or you can configure the following alternative functions:

— TACAP, TACK, TAOUT, TAPWM , Watch Timer, Buzzer output and KIN0-KIN3 inputs

Port 3 Control Registers (P3CON)

A reset clears the P3CON registers to “00H”, configuring all pins to input mode. You use control registers settings to select input or output mode, and enable the alternative functions.

When programming this port, please remember that any alternative peripheral I/O function you configure using the port 3 control registers must also be enabled in the associated peripheral module.

Figure 9-13. Port 4 Control Register (P4CON)

10 BASIC TIMER

OVERVIEW

BASIC TIMER (BT)

You can use the basic timer (BT) in two different ways:

— As a watchdog timer to provide an automatic reset mechanism in the event of a system malfunction.

— To signal the end of the required oscillation stabilization interval after a reset or a Stop mode release.

The functional components of the basic timer block are:

— Clock frequency divider (fxx divided by 4096, 1024 or 128) with multiplexer

— 8-bit basic timer counter, BTCNT (set 1, bank 0, FDH, read-only)

— Basic timer control register, BTCON (set 1, D3H, read/write)

BASIC TIMER CONTROL REGISTER (BTCON)

The basic timer control register, BTCON, is used to select the input clock frequency, to clear the basic timer counter and frequency dividers, and to enable or disable the watchdog timer function. It is located in set 1, address D3H, and is read/write addressable using register addressing mode.

A reset clears BTCON to '00H'. This enables the watchdog function and selects a basic timer clock frequency of $f_{XX}/4096$. To disable the watchdog function, write the signature code '1010B' to the basic timer register control bits BTCON.7–BTCON.4.

The 8-bit basic timer counter, BTCNT (set 1, bank 0, FDH), can be cleared at any time during normal operation by writing a "1" to BTCON.1. To clear the frequency dividers, write a "1" to BTCON.0.

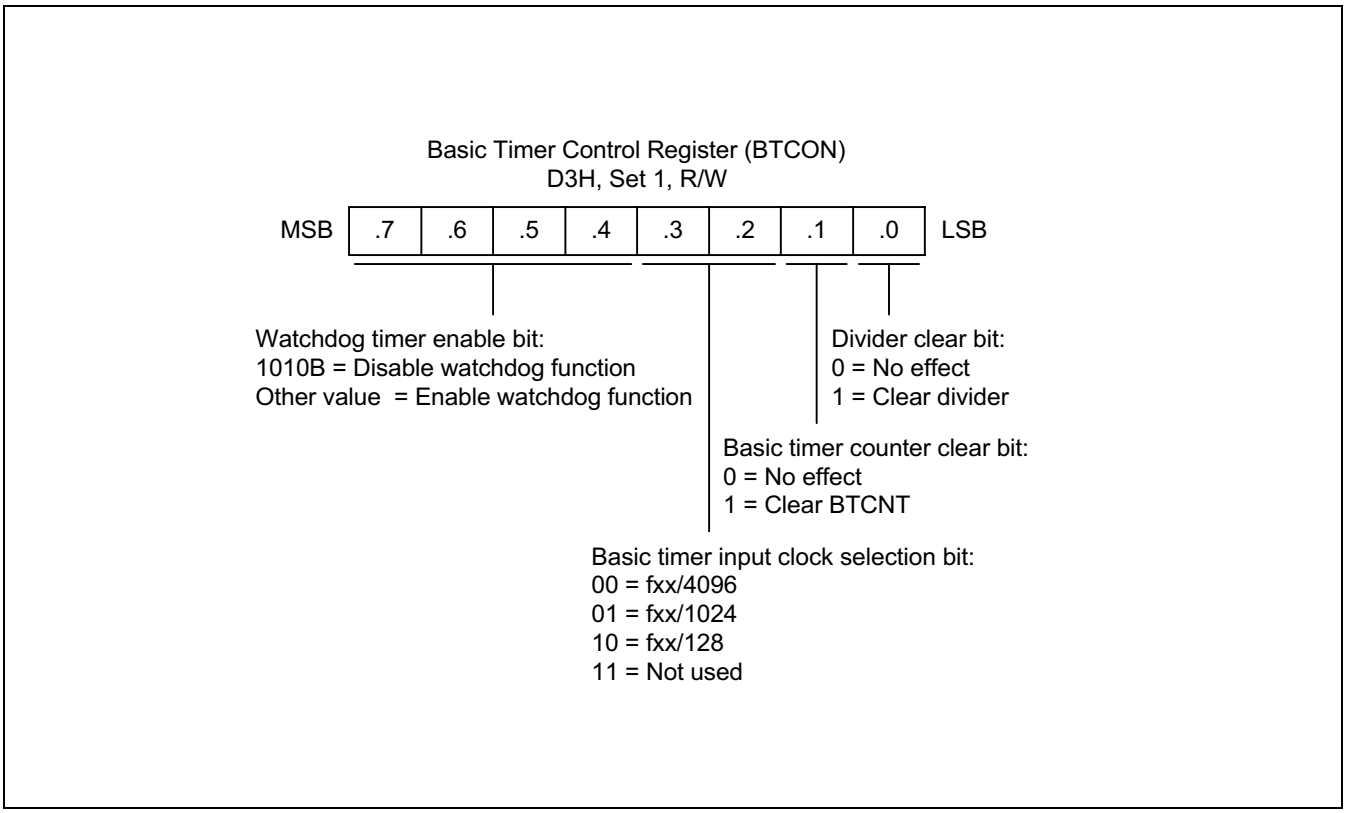

Figure 10-1. Basic Timer Control Register (BTCON)

BASIC TIMER FUNCTION DESCRIPTION

Watchdog Timer Function

You can program the basic timer overflow signal (BTOVF) to generate a reset by setting BTCON.7–BTCON.4 to any value other than "1010B". (The "1010B" value disables the watchdog function.) A reset clears BTCON to "00H", automatically enabling the watchdog timer function. A reset also selects the CPU clock (as determined by the current CLKCON register setting), divided by 4096, as the BT clock.

The MCU is reseted whenever a basic timer counter overflow occurs, During normal operation, the application program must prevent the overflow, and the accompanying reset operation, from occuring, To do this, the BTCNT value must be cleared (by writing a “1” to BTCON.1) at regular intervals.

If a system malfunction occurs due to circuit noise or some other error condition, the BT counter clear operation will not be executed and a basic timer overflow will occur, initiating a reset. In other words, during the normal operation, the basic timer overflow loop (a bit 7 overflow of the 8-bit basic timer counter, BTCNT) is always broken by a BTCNT clear instruction. If a malfunction does occur, a reset is triggered automatically.

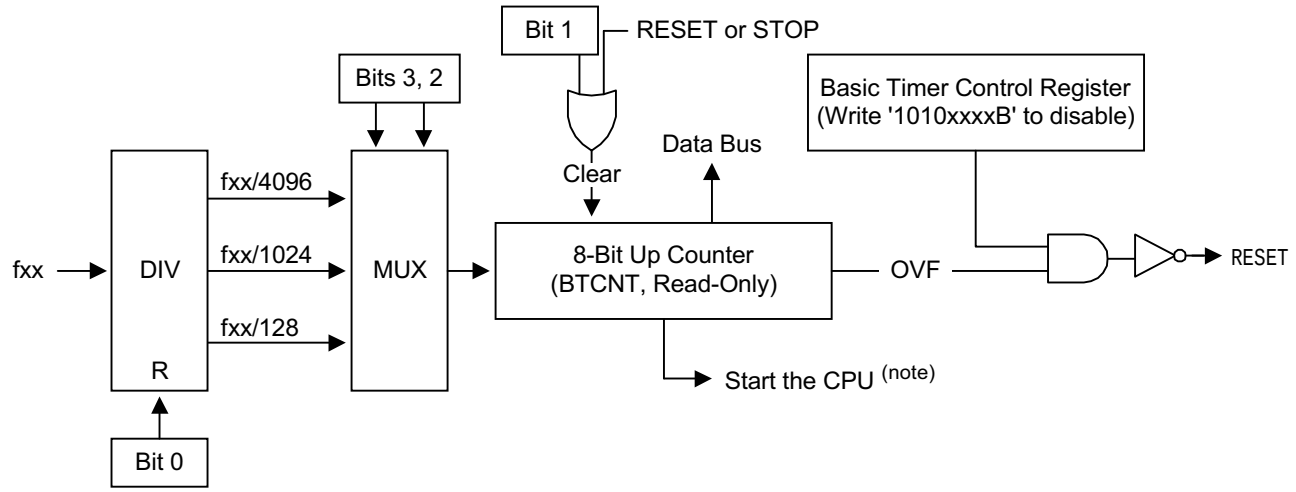
Oscillation Stabilization Interval Timer Function

You can also use the basic timer to program a specific oscillation stabilization interval following a reset or when Stop mode has been released by an external interrupt.

In Stop mode, whenever a reset or an external interrupt occurs, the oscillator starts. The BTCNT value then starts increasing at the rate of fxx/4096 (for reset), or at the rate of the preset clock source (for an external interrupt). When BTCNT.4 overflows, a signal is generated to indicate that the stabilization interval has elapsed and to gate the clock signal off to the CPU so that it can resume normal operation.

In summary, the following events occur when stop mode is released:

1. During stop mode, a power-on reset or an interrupt occurs to trigger the Stop mode release and oscillation starts.
2. If a power-on reset occurred, the basic timer counter will increase at the rate of fxx/4096. If an interrupt is used to release stop mode, the BTCNT value increases at the rate of the preset clock source.
3. Clock oscillation stabilization interval begins and continues until bit 4 of the basic timer counter overflows.
4. When a BTCNT.4 overflow occurs, normal CPU operation resumes.



NOTE: During a power-on reset operation, the CPU is idle during the required oscillation stabilization interval (until bit 4 of the basic timer counter overflows).

Figure 10-2. Basic Timer Block Diagram

11 8-BIT TIMER A/B

8-BIT TIMER A

OVERVIEW

The 8-bit timer *A* is an 8-bit general-purpose timer/counter. Timer A has three operating modes, you can select one of them using the appropriate TACON setting:

— Interval timer mode (Toggle output at TAOUT pin)
— Capture input mode with a rising or falling edge trigger at the TACAP pin
— PWM mode (TAPWM)

Timer A has the following functional components:

— Clock frequency divider (fxx divided by 1024, 256, or 64) with multiplexer
— External clock input pin (TACK)
— 8-bit counter (TACNT), 8-bit comparator, and 8-bit reference data register (TADATA)
— I/O pins for capture input (TACAP) or PWM or match output (TAPWM, TAOUT)
— Timer A overflow interrupt (IRQ0, vector E0H) and match/capture interrupt (IRQ0, vector DEH) generation
— Timer A control register, TACON (set 1, bank0, EAH, read/write)

FUNCTION DESCRIPTION

Timer A Interrupts (IRQ0, Vectors DEH and E0H)

The timer A module can generate two interrupts: the timer A overflow interrupt (TAOVF), and the timer A match/ capture interrupt (TAINT). TAOVF is interrupt level IRQ0, vector E0H. TAINT also belongs to interrupt level IRQ0, but is assigned the separate vector address, DEH.

A timer A overflow interrupt pending condition is automatically cleared by hardware when it has been serviced. A timer A match/capture interrupt, TAINT pending condition is also cleared by hardware when it has been serviced.

Interval Timer Function

The timer A module can generate an interrupt: the timer A match interrupt (TAINT). TAINT belongs to interrupt level IRQ0, and is assigned the separate vector address, DEH.

When timer A measure interrupt occurs and is serviced by the CPU, the pending condition is cleared automatically by hardware.

In interval timer mode, a match signal is generated and TAOUT is toggled when the counter value is identical to the value written to the TA reference data register, TADATA. The match signal generates a timer A match interrupt (TAINT, vector DEH) and clears the counter.

If, for example, you write the value 10H to TADATA and 0AH to TACON, the counter will increment until it reaches 10H. At this point, the TA interrupt request is generated, the counter value is reset, and counting resumes.

Pulse Width Modulation Mode

Pulse width modulation (PWM) mode lets you program the width (duration) of the pulse that is output at the TAPWM pin. As in interval timer mode, a match signal is generated when the counter value is identical to the value written to the timer A data register. In PWM mode, however, the match signal does not clear the counter. Instead, it runs continuously, overflowing at FFH, and then continues incrementing from 00H.

Although you can use the match signal to generate a timer A overflow interrupt, interrupts are not typically used in PWM-type applications. Instead, the pulse at the TAPWM pin is held to Low level as long as the reference data value is *less than or equal to* (≤) the counter value and then the pulse is held to High level for as long as the data value is *greater than* (>) the counter value. One pulse width is equal to $t_{CLK} \cdot 256$.

Capture Mode

In capture mode, a signal edge that is detected at the TACAP pin opens a gate and loads the current counter value into the TA data register. You can select rising or falling edges to trigger this operation.

Timer A also gives you capture input source: the signal edge at the TACAP pin. You select the capture input by setting the value of the timer A capture input selection bit in the port 3 control register, P3CON, (set 1, bank 1, E8H). When P3CONL.7.6 is 00, the TACAP input or normal input is selected. When P3CON.7.6 is set to 10, normal output is selected.

Both kinds of timer A interrupts can be used in capture mode: the timer A overflow interrupt is generated whenever a counter overflow occurs; the timer A match/capture interrupt is generated whenever the counter value is loaded into the TA data register.

By reading the captured data value in TADATA, and assuming a specific value for the timer A clock frequency, you can calculate the pulse width (duration) of the signal that is being input at the TACAP pin.

TIMER A CONTROL REGISTER (TACON)

You use the timer A control register, TACON, to

— Select the timer A operating mode (interval timer, capture mode and PWM mode)

— Select the timer A input clock frequency

— Clear the timer A counter, TACNT

— Enable the timer A overflow interrupt or timer A match/capture interrupt

— Clear timer A match/capture interrupt pending conditions

TACON is located in set 1, Bank 0 at address EAH, and is read/write addressable using Register addressing mode.

A reset clears TACON to '00H'. This sets timer A to normal interval timer mode, selects an input clock frequency of fxx/1024, and disables all timer A interrupts. You can clear the timer A counter at any time during normal operation by writing a "1" to TACON.3.

The timer A overflow interrupt (TAOVF) is interrupt level IRQ0 and has the vector address E0H. When a timer A overflow interrupt occurs and is serviced by the CPU, the pending condition is cleared automatically by hardware.

To enable the timer A match/capture interrupt (IRQ0, vector DEH), you must write TACON.1 to "1". To generate the exact time interval, you should write TACON.3 and .0, which cleared counter and interrupt pending bit. When interrupt service routine is served, the pending condition must be cleared by software by writing a '0' to the interrupt pending bit.

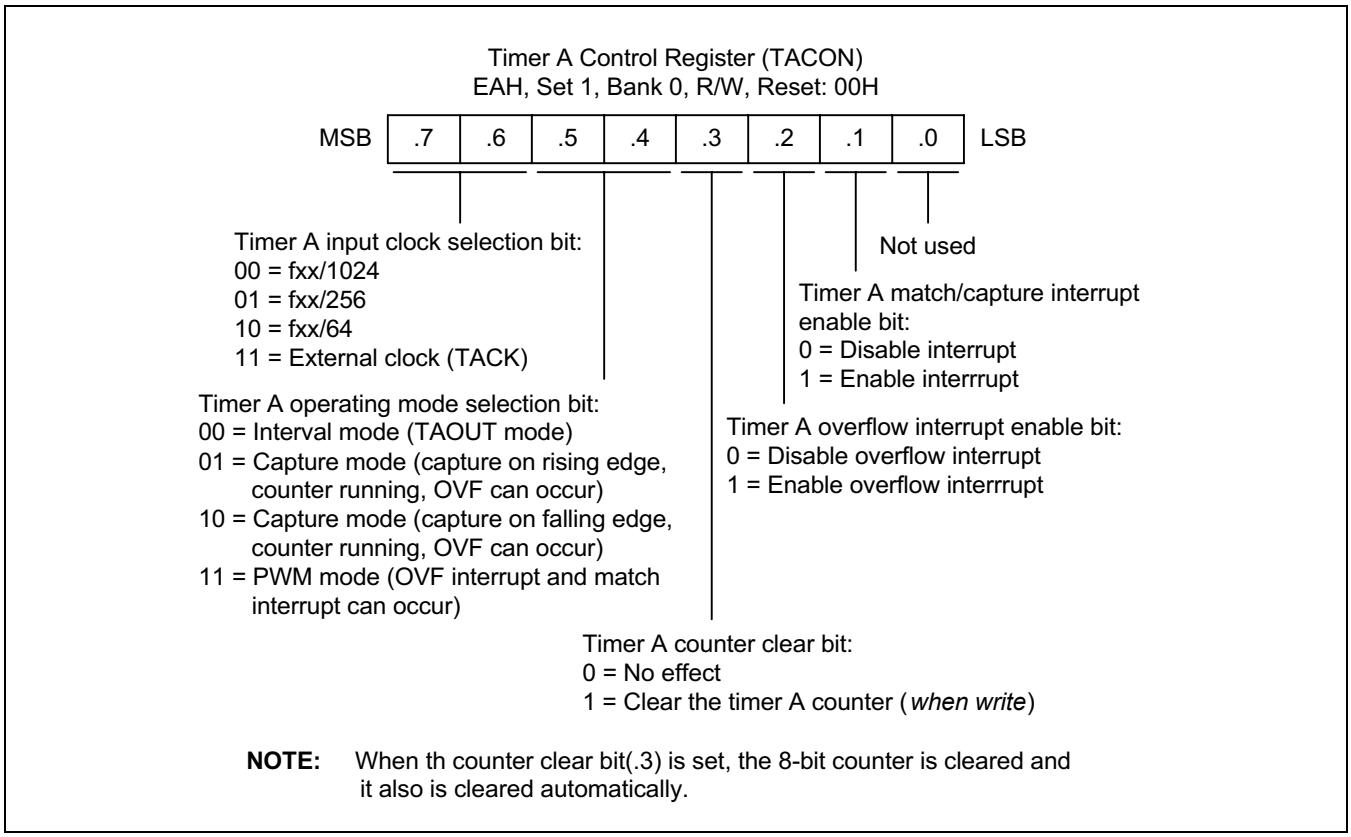


Figure 11-1. Timer A Control Register (TACON)

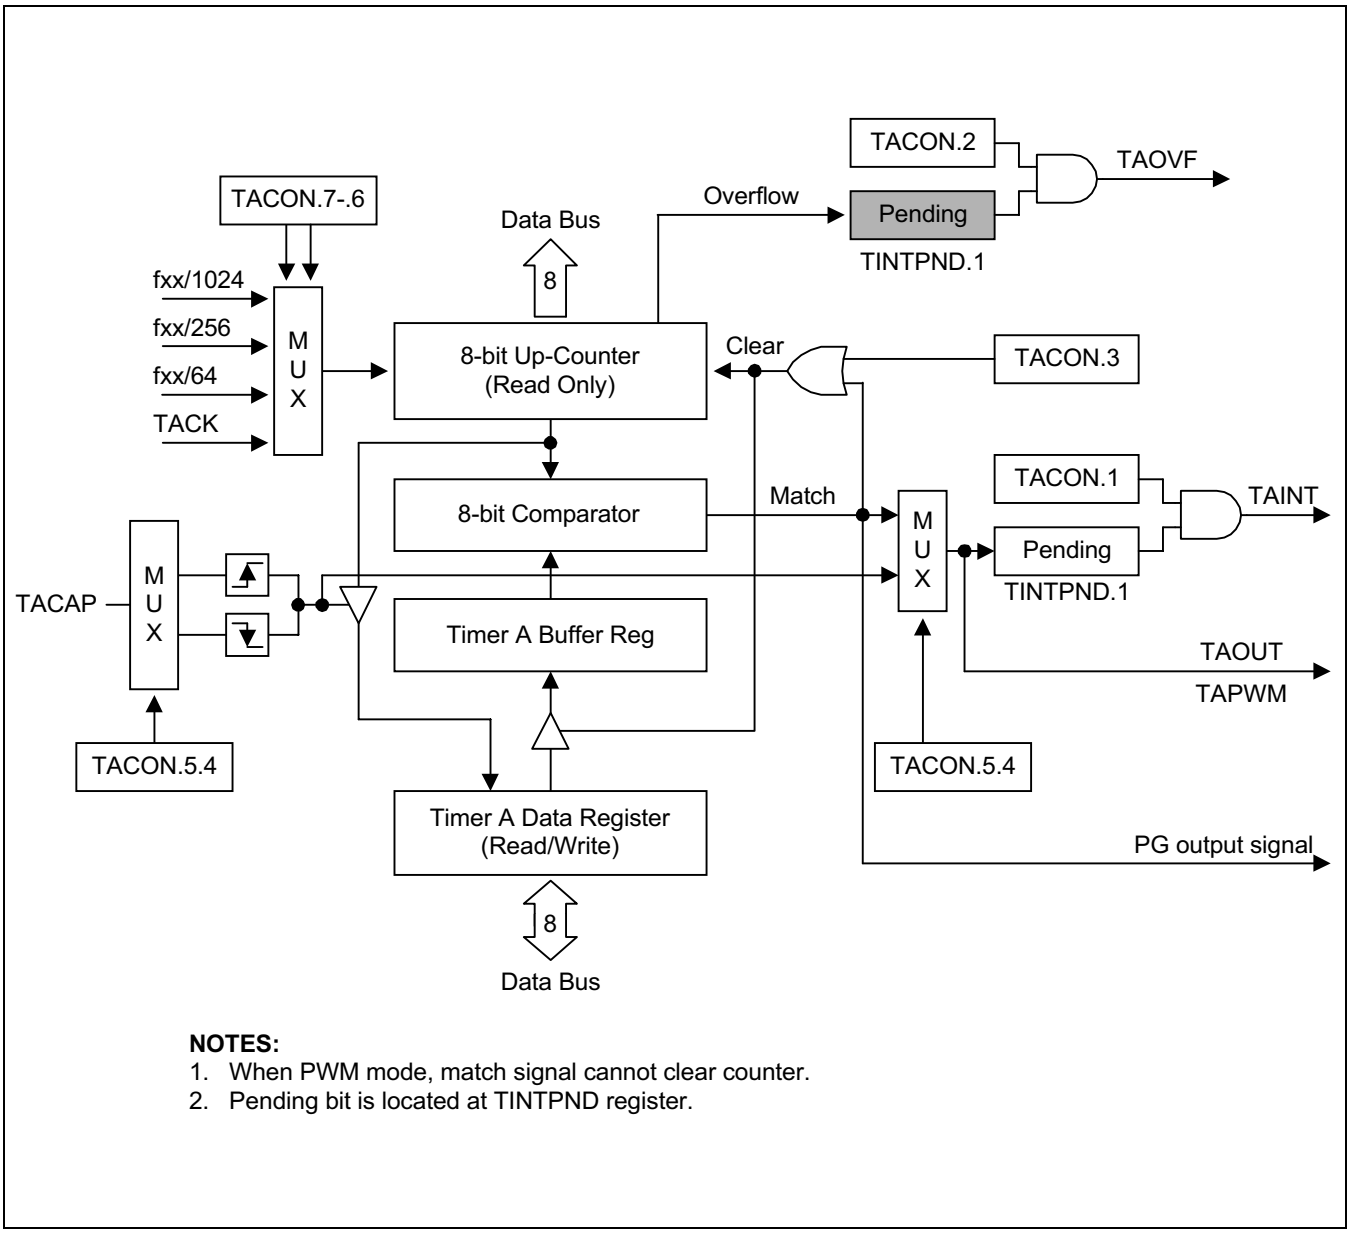
BLOCK DIAGRAM



NOTES:
1. When PWM mode, match signal cannot clear counter.
2. Pending bit is located at TINTPND register.

Figure 11-2. Timer A Functional Block Diagram

8-BIT TIMER B

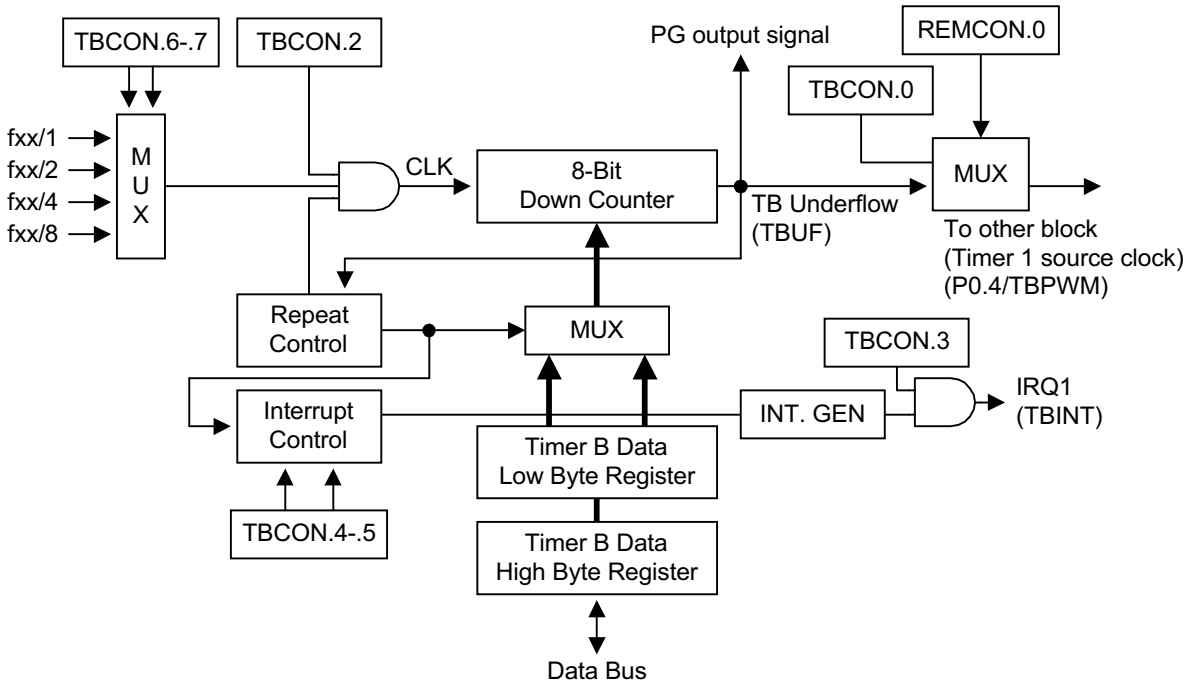
OVERVIEW

The S3C8238/C8235/F8235 micro-controller has an 8-bit counter called timer B. Timer B, which can be used to generate the carrier frequency of a remote controller signal.

Timer B has two functions:

— As a normal interval timer, generating a timer B interrupt at programmed time intervals.

— To supply a clock source to the 16-bit timer/counter module, timer 1, for generating the timer 1 overflow interrupt.



NOTE: In case of setting TBCON.5-.4 at '10', the value of the TBDATAL register is loaded into the 8-bit counter when the operation of the timer B starts. And then if a underflow occurs in the counter, the value of the TBDATAH register is loaded with the value of the 8-bit counter. However, if the next borrow occurs, the value of the TBDATAL register is loaded with the value of the 8-bit counter. To output TBPWM as carrier wave, you have to set P0CON.1-.0 as "11" and also set REMCON.0 as '1'.

NOTES

12 16-BIT CAPTURE TIMER 1

OVERVIEW

The 16-bit timer 1 is an 16-bit general-purpose timer/counter. Timer 1 has three operating modes, one of which you select using the appropriate T1CON setting.

— Interval timer mode (Toggle output at T1OUT pin)

— Capture input mode with a rising or falling edge trigger at the T1CAP pin

Timer 1 has the following functional components:

— Clock frequency divider (fxx divided by 64, 8 or 1) with multiplexer

— External clock input pin (T1CK, TBUF)

— A 16-bit counter (T1CNTH/L), a 16-bit comparator, and two 16-bit reference data register (T1DATA1, T1DATA2)

— I/O pins for capture input (T1CAP), or match output (T1OUT)

— Timer 1 overflow interrupt (IRQ2, vector E6H) and match/capture interrupt (IRQ2, vector E4H) generation

— Timer 1 control register, T1CON (set 1, F1H, Bank 1, read/write)

FUNCTION DESCRIPTION

Timer 1 Interrupts (IRQ2, Vectors E4H and E6H)

The timer 1 module can generate two interrupts, the timer 1 overflow interrupt (T1OVF), and the timer 1 match/capture interrupt (T1INT). T1OVF is interrupt level IRQ2, vector E6H. T1INT also belongs to interrupt level IRQ2, but is assigned the separate vector address, E4H.
A timer 1 overflow interrupt pending condition is automatically cleared by hardware when it has been serviced.
A timer 1 match/capture interrupt, T1INT pending condition is also cleared by hardware when it has been serviced.

Interval Mode (match)

The timer 1 module can generate an interrupt: the timer 1 match interrupt (T1INT). T1INT belongs to interrupt level IRQ2, and is assigned the separate vector address, E4H.

In interval timer mode, a match signal is generated and T1OUT is toggled when the counter value is identical to the value written to the T1 reference data register, T1DATA1H/L. The match signal generates a timer 1 match interrupt (T1INT, vector E4H) and clears the counter.

Capture Mode

In capture mode, a signal edge that is detected at the T1CAP pin opens a gate and loads the current counter value into the T1 data register (T1DATA1H/L for rising edge, T1DATA2H/L for falling edge). You can select rising or falling edges to trigger this operation.

Timer 1 also gives you capture input source, the signal edge at the T1CAP pin. You select the capture input by setting the value of the timer 1 capture input selection bit in the port 1 control register high, P1CONH, (set 1 bank 0, E0H). When P1CONH.7-.6 is 00 or 11, the T1CAP input is selected .

Both kinds of timer 1 interrupts (T1OVF, T1INT) can be used in capture mode, the timer 1 overflow interrupt is generated whenever a counter overflow occurs, the timer 1 capture interrupt is generated whenever the counter value is loaded into the T1 data register.

By reading the captured data value in T1DATAH/L, and assuming a specific value for the timer 1 clock frequency, you can calculate the pulse width (duration) of the signal that is being input at the T1CAP pin.

TIMER 1 CONTROL REGISTER (T1CON)

You use the timer 1 control register, T1CON, to

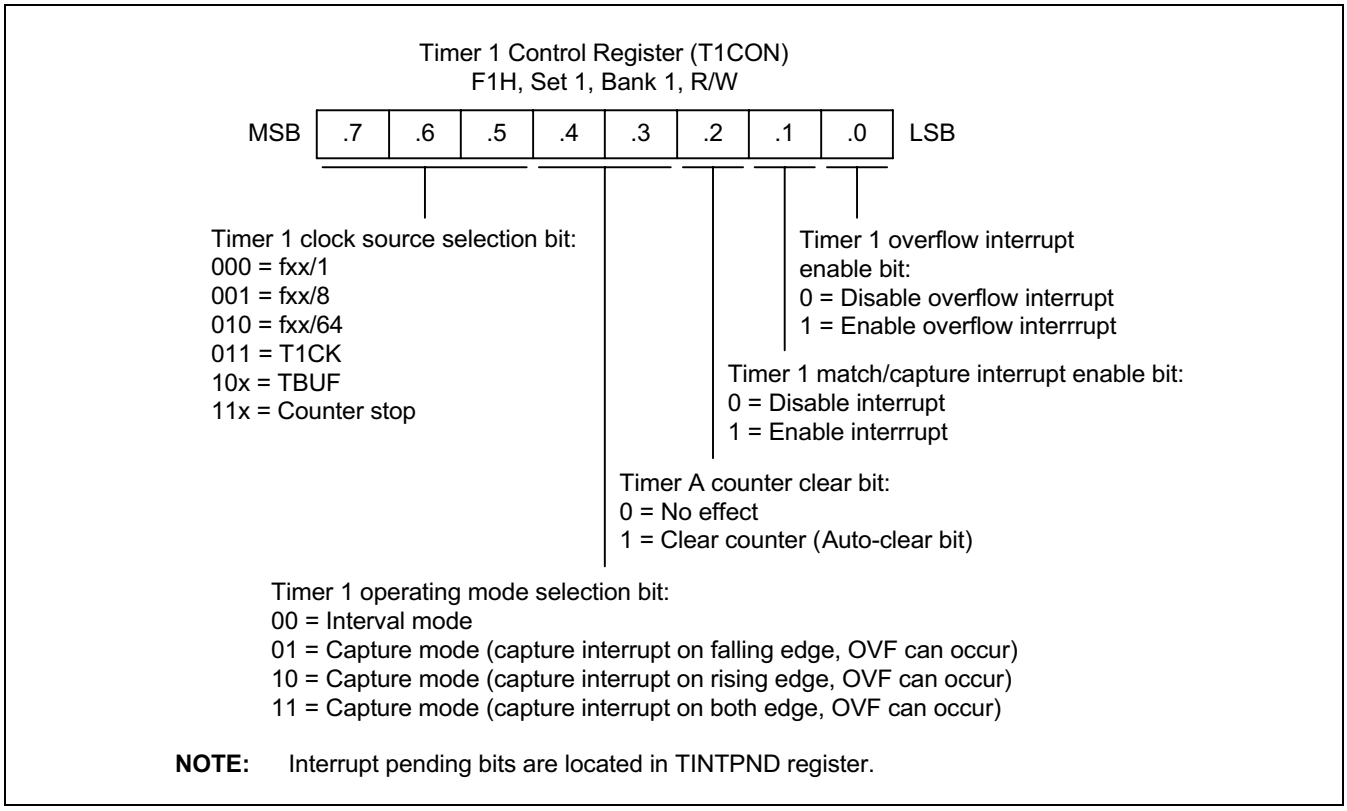
— Select the timer 1 operating mode (interval timer, capture mode)
— Select the timer 1 input clock frequency
— Clear the timer 1 counter, T1CNTH/L
— Enable the timer 1 overflow interrupt or timer 1 match/capture interrupt
— Clear timer 1 match/capture interrupt pending conditions

T1CON is located in set 1 and Bank 1 at address F1H, and is read/write addressable using Register addressing mode.

A reset clears T1CON to '00H'. This sets timer 1 to normal interval timer mode, selects an input clock frequency of fxx/1024, and disables all timer 1 interrupts. To disable the counter operation, please set T1CON.7-.5 to 111B. You can clear the timer 1 counter at any time during normal operation by writing a "1" to T1CON.3.
The timer 1 overflow interrupt (T1OVF) is interrupt level IRQ2 and has the vector address E6H.

To detect a match/capture or overflow interrupt pending condition when T1INT or T1OVF is disabled, the application program should poll the pending bit TINTPND register, bank 0 E9H. When a "1" is detected, a timer 1 match/capture or overflow interrupt is pending.
When the sub-routine has been serviced, the pending condition must be cleared by software by writing a "0" to the interrupt pending bit.

If interrupt(match/capture or overflow) are enabled, the pending bit is cleared automatically by hardware.



NOTE: Interrupt pending bits are located in TINTPND register.

Figure 12-1. Timer 1 Control Register (T1CON)

BLOCK DIAGRAM

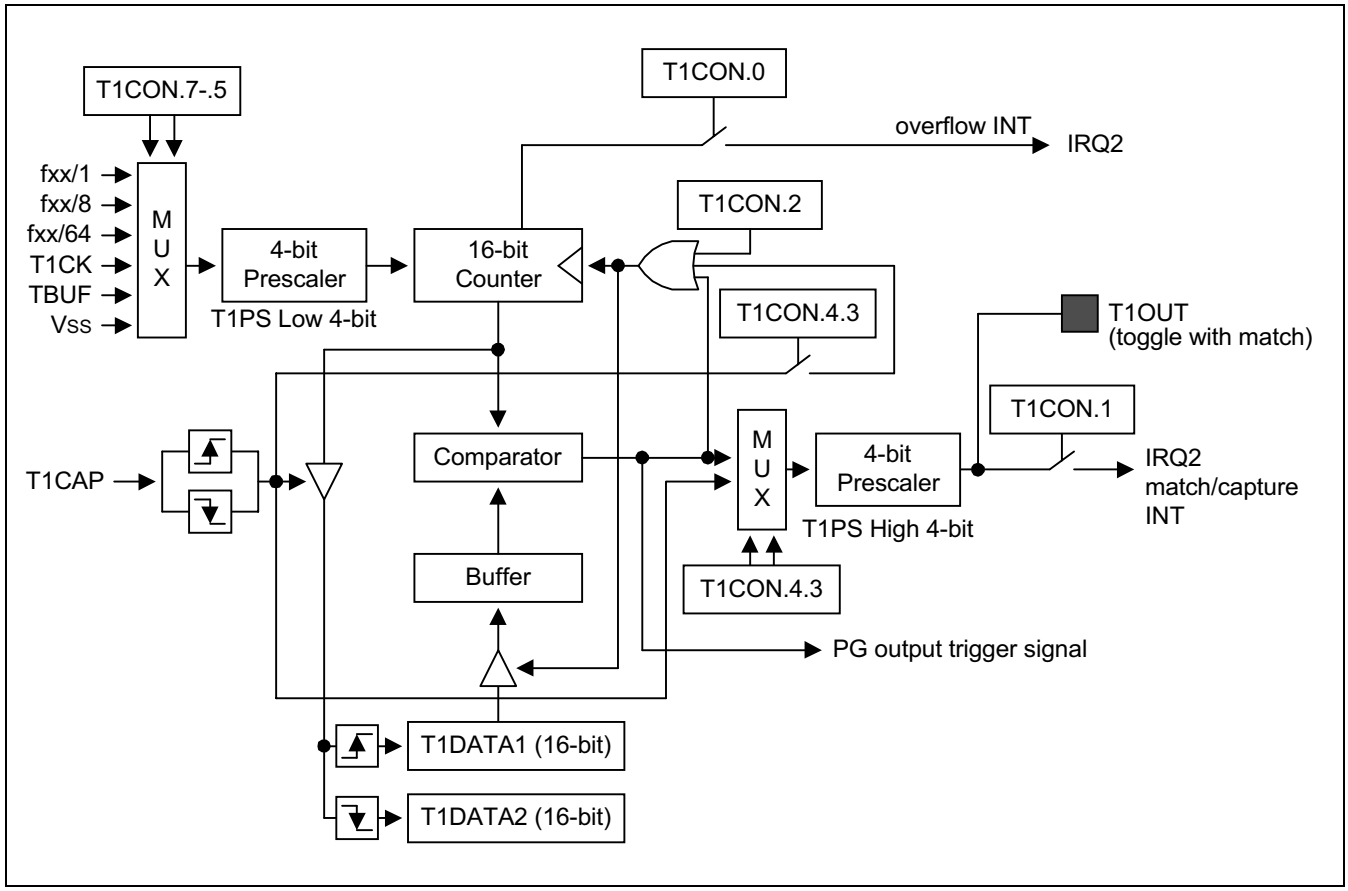


Figure 12-2. Timer 1 Functional Block Diagram

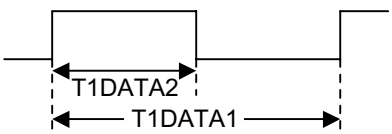
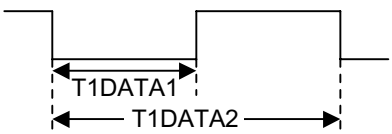
NOTES:

1. When capture mode is running, the 16-bit counter must be cleared if capture signal is inputted. An actual time of capture operation is determined by P0CONH.7.6 register, on the contrary T1CON.4.3 determines the period of interrupt.
2. In interval mode, only T1DATA1 register is used for comparison with the 16-bit counter. (T1DATA2 register is not used.)
3. In 4-bit prescaler using low 4-bit of T1PS register, the clock frequency inputted to the 16-bit counter is divided by (m+1) where the value of low 4-bit is m. Similarly, with 4-bit prescaler using high 4-bit the frequency of T1OUT signal is divided by (n+1) where the value of high 4-bit is n.
4. If you set P0CONH.7-.6 at “00” T1DATA1 used as period is loaded with T1CNT at rising edge when T1CNT is cleared. T1DATA2 used as upper duration is loaded with T1CNT at falling edge when T1CNT continues to increase. If you set P0CONH.7-.6 at “11” T1DATA1 used as lower duration is loaded with T1CNT at rising edge when T1CNT continues to increase. T1DATA2 used as period is loaded with T1CNT at falling edge when T1CNT is cleared. T1CON4.-.3 informs only when capture occurs. Only T1DATA1 is used to compare to T1CNT in match mode. When setting T1CON.2, T1CNT is cleared and buffer to compare to T1CNT is loaded with T1DATA1.



T1CON.4-.3 = 01, 10 or 11 but 00
P0CONH.7-.6 = 00 (Rising Start)



T1CON.4-.3 = 01, 10 or 11 but 00
P0CONH.7-.6 = 11 (Falling Start)

NOTES

13 WATCH TIMER

OVERVIEW

Watch timer functions include real-time and watch-time measurement and interval timing for the system clock. To start watch timer operation, set bit 1 and bit 6 of the watch timer mode register, WTCON.1 and .6, to "1". After the watch timer starts and elapses a time, the watch timer interrupt is automatically set to "1", and interrupt requests commence in 3.9ms, 0.25 s, 0.5s or 1.0s intervals.

The watch timer can generate a steady 0.5kHz, 1kHz, 2 kHz or 4 kHz signal to the BUZZER output. By setting WTCON.3 and WTCON.2 to "11b", the watch timer will function in high-speed mode, generating an interrupt every 3.91 ms. High-speed mode is useful for timing events for program debugging sequences.
The watch timer supplies the clock frequency for the LCD controller (f_{LCD}). Therefore, **if the watch timer is disabled, the LCD controller does not operate**.

14 LCD CONTROLLER/DRIVER

OVERVIEW

The S3F8325 micro-controller can directly drive an up-to-24-digit (24-segment) LCD panel. The LCD module has the following components:

— LCD controller/driver
— Display RAM (00H-17H) for storing display data in page 2
— 24 segment output pins (SEG0 - SEG23)
— 8 common output pins (COM0 - COM7)
— 4 LCD operating power supply pins (V_{LC1} –V_{LC4})

Bit settings in the LCD mode register, LMOD, determine the LCD frame frequency, duty and bias, and the segment pins used for display output. When a subsystem clock is selected as the LCD clock source, the LCD display is enabled even during stop and idle modes.

The LCD control register LCON turns the LCD display on and off and switches current to the charge-pump circuits for the display. LCD data stored in the display RAM locations are transferred to the segment signal pins automatically without program control.

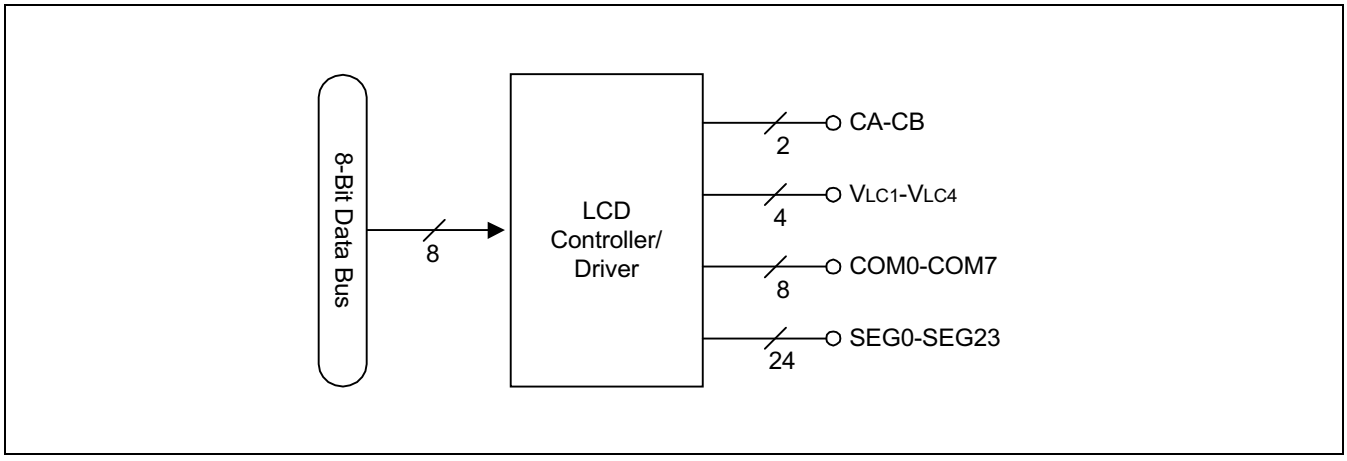

Figure 14-1. LCD Function Diagram

LCD CIRCUIT DIAGRAM

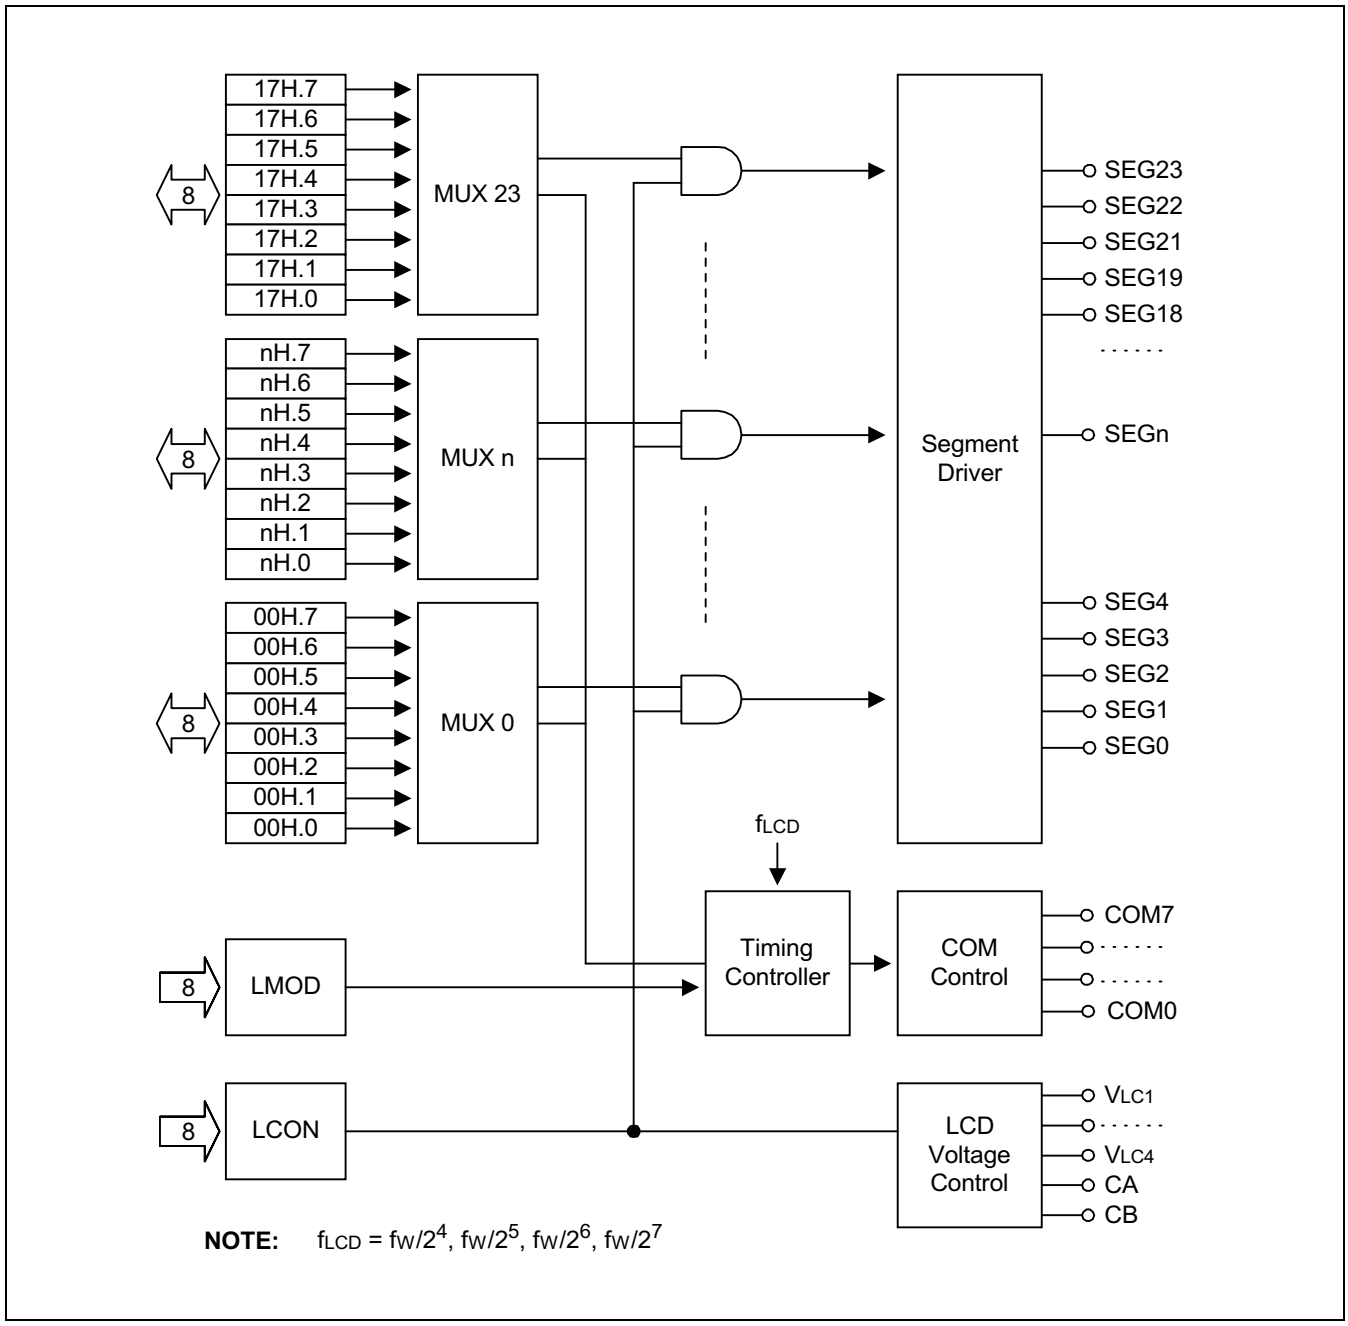

Figure 14-2. LCD Circuit Diagram

LCD RAM ADDRESS AREA

RAM addresses 00H-17H of page 2 are used as LCD data memory. When the bit value of a display segment is "1", the LCD display is turned on; when the bit value is "0", the display is turned off.

Display RAM data are sent out through segment pins SEG0-SEG23 using a direct memory access (DMA) method that is synchronized with the f_{LCD} signal. RAM addresses in this location that are not used for LCD display can be allocated to general-purpose use.

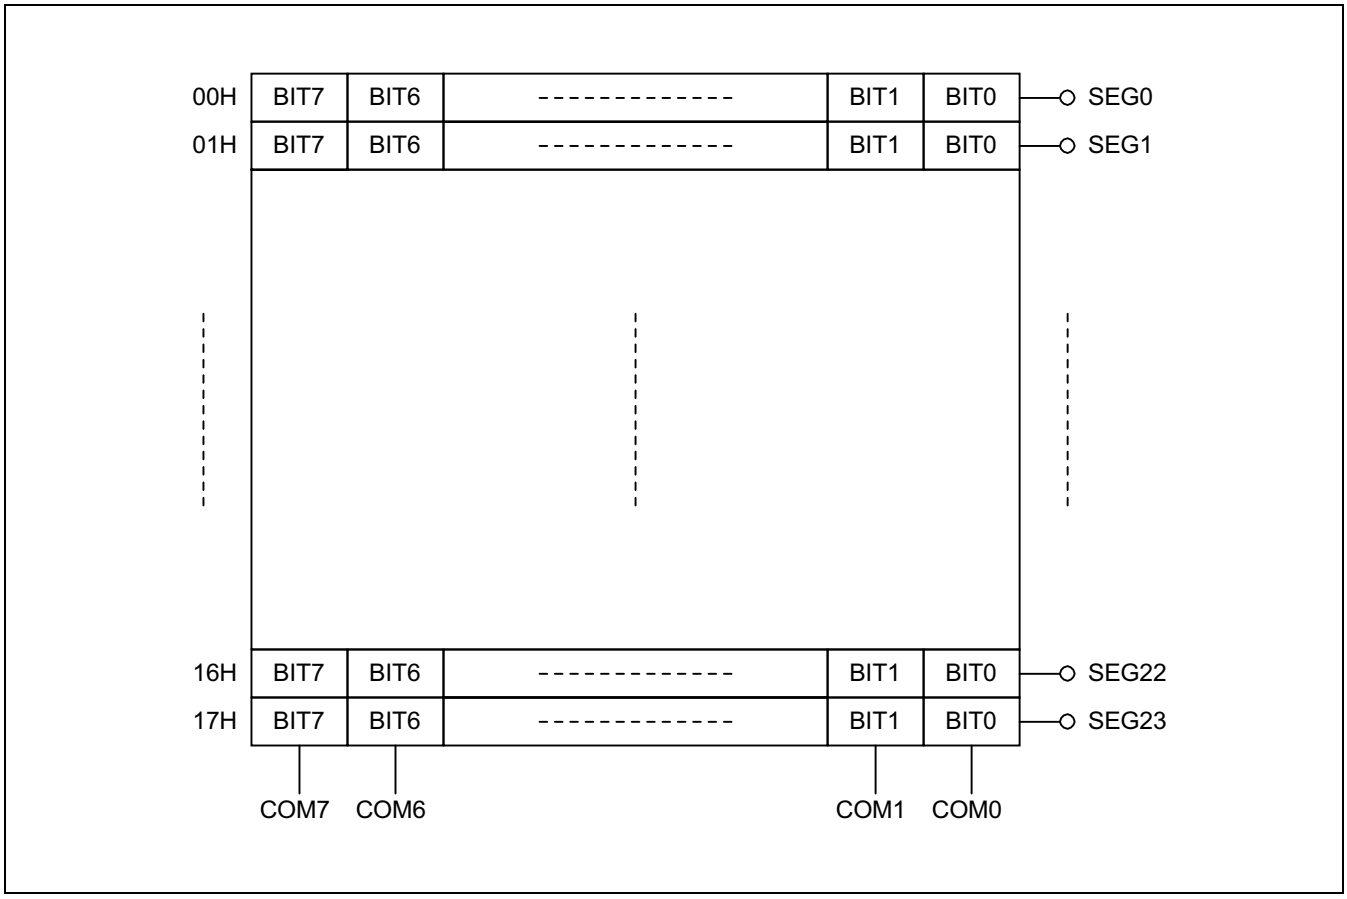

Figure 14-3. LCD Display Data RAM Organization

LCD CONTROL REGISTER (LCON), D0H

Table 14-1. LCD Control Register (LCON) Organization

LCON Bit	Setting	Description
LCON.7-.5	000	0.90V (Booster reference voltage)
	001	0.95V
	010	1.00V
	011	1.05V
	100	1.10V
	101	1.15V
	110	1.20V
	111	1.25V
LCON.4	Not used	
LCON.3-.2	00	Off signal
LCD dot on/off	01	On signal
control bit	1x	Normal display
LCON.1-.0	00	Internal CAP bias; display off (Low signal output through COM/SEG) Booster Off
	01	Internal CAP bias; display on (Valid signal output through COM/SEG)
	1x	External resistor bias; Booster Off; display on (Valid signal output through COM/SEG)

NOTE: To configure SEG12-23 and COM4-7 as COM/SEG output, port control register must be configured output mode previously .

LCD MODE REGISTER (LMOD)

The LCD mode control register LMOD is mapped to RAM addresses D1H.

LMOD controls these LCD functions:

— Duty and bias selection (LMOD.1-LMOD.0)

— LCDCK clock frequency selection (LMOD.3-LMOD.2)

The LCD clock signal, LCDCK, determines the frequency of COM signal scanning of each segment output. This is also referred to as the 'frame frequency.' Since LCDCK is generated by dividing the watch timer clock (fw), the watch timer must be enabled when the LCD display is turned on. RESET clears the LMOD and LCON register values to logic zero. This produces the following LCD control settings:

— Display is turned off

— LCDCK frequency is the watch timer clock (fw)/2^7 = 256 Hz

The LCD display can continue to operate during idle and stop modes if a subsystem clock is used as the watch timer source. The LCD output voltage level is supplied by the voltage booster.

Table 14-2. LCD Mode register

LMOD Bit	Setting	Description
LMOD.7	0	SEG20 - SEG23 output disable
	1	SEG20 - SEG23 output enable
LMOD.6	0	SEG16 - SEG19 output disable
	1	SEG16 - SEG19 output enable
LMOD.5	0	SEG12 - SEG15 output disable
	1	SEG12 - SEG15 output enable
LMOD.4	0	COM4 - COM7 output disable
	1	COM4 - COM7 output enable

Table 14-3. Frame Frequency according to LCD Clock Signal (LCDCK)

LMOD.3, .2 (LCDCK)	Static (COM0)	1/4 Duty (COM0-COM3)	1/8 Duty (COM0-COM7)
00 : (fw) / 2^7	256	64	32
01 : (fw) / 2^6	512	128	64
10 : (fw) / 2^5	1024	256	128
11 : (fw) / 2^4	2048	512	256

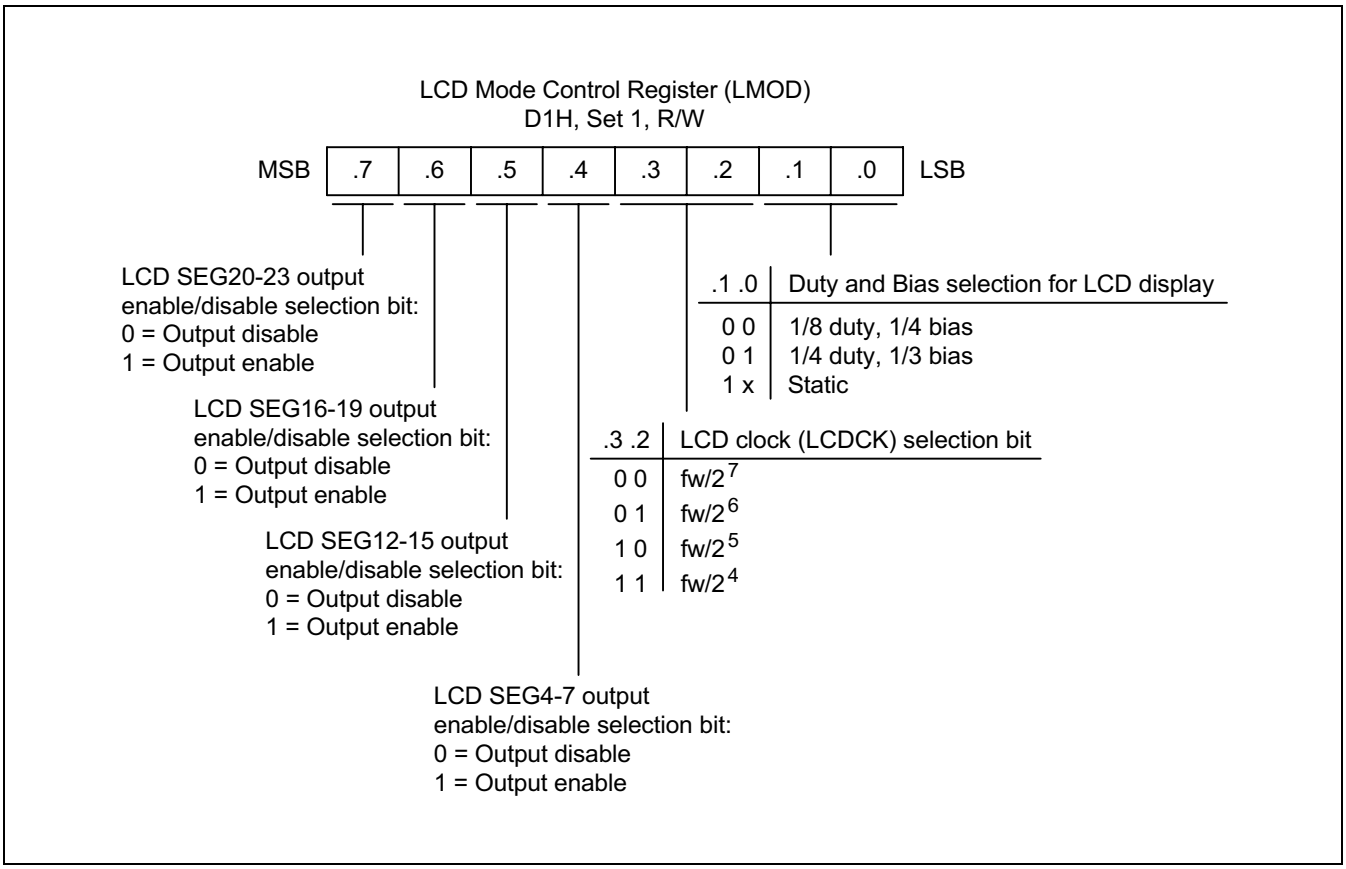

Figure 14-4. LCD Mode Contol Register

LCD KEY STROBE OUTPUT MODE

The LCD segment output pins(SEG12-SEG23) can also output key strobe signal for key scan and KIN0-KIN3 pins check key-press.

When SEG12-SEG23 are set as key strobe output, selected key strobe is output pin by pin continuously with selected interval and duration.

When KIN# pins are set as an alternative mode, KIN# pins status is high impedance normally, but when key strobe is output through SEG# pins, KIN# pins status become pull-up enable input mode.

To decide which SEG# pin output key strobe you should check P2 and P4 data register. If all SEG12-SEG23 are used as key strobe output, KSDATA data register are used as one 12-bit data register. If SEG16-SEG23 are used as key strobe output, KSDATA data register constains one number between 5 and 12. If SEG20-SEG23 are used as key strobe output, KSDATA data register constains one number between 9 and 12. KSDATA data register value is not changed until next strobe occurs.

To decide which KIN# pin receive key strobe you should check P3PND register in interrupt routine. So, check KSDATA data register and P3PND register and you will get the key-press information.

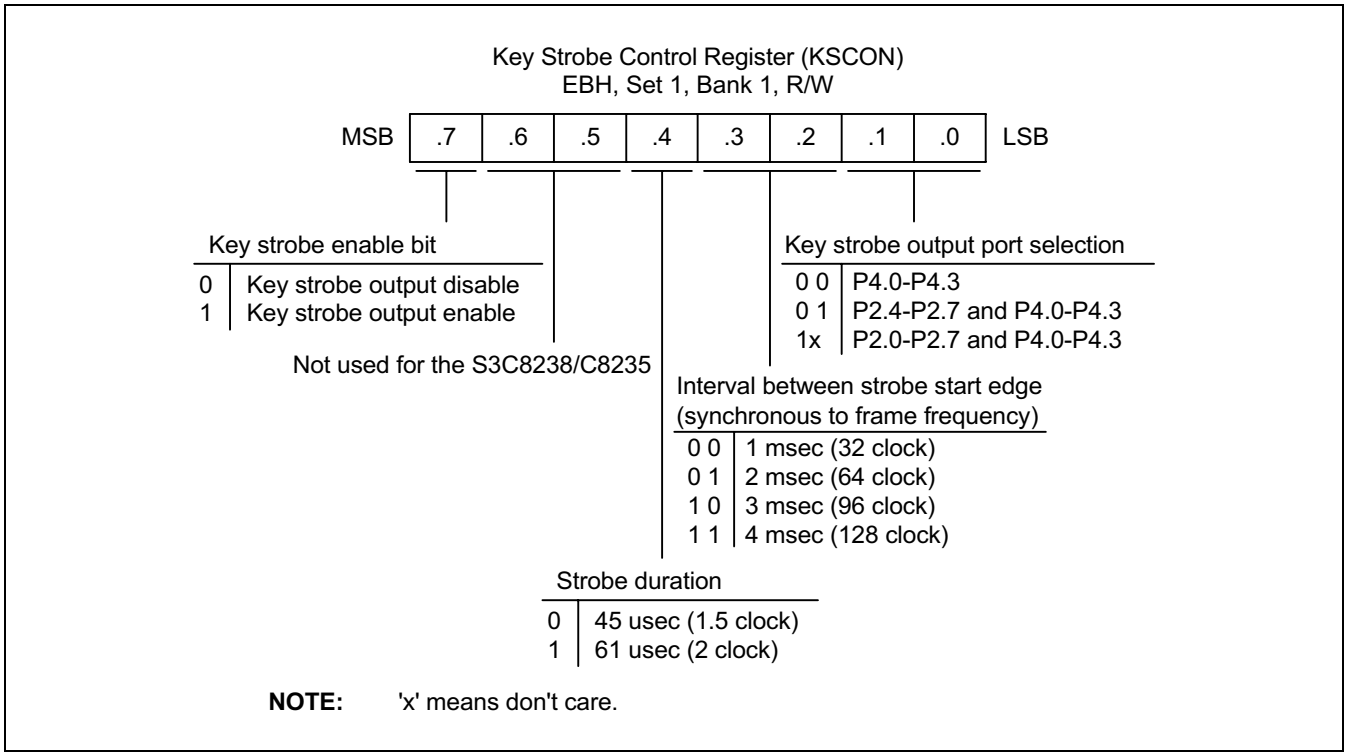

Figure 14-5. Key Strobe Contol Register

NOTES:

1. When you want to configure SEG12-SEG23 pins as key strobe output, you must configure P2 and P4 output mode previously.
2. To enable key input you must configure P3CONL as input mode(external interrupt) or alternative mode.
3. If SEG12-SEG23 pins are used as only key strobe output, P3 should be configured input mode(external Interrupt), but SEG12-SEG23 pins are used as both SEG signal output and key strobe output, P3 should be configured alternative mode.

LCD DRIVE VOLTAGE

The LCD display is turned on only when the voltage difference between the common and segment signals is greater than V_{LCD}. The LCD display is turned off when the difference between the common and segment signal voltages is less than V_{LCD}. The turn-on voltage, + V_{LCD} or - V_{LCD}, is generated only when both signals are the selected signals of the bias. Table 14-7 shows LCD drive voltages for static mode, 1/3 bias, and 1/4 bias.

Table 14-4. LCD Drive Voltage Values (External Resistor Bias)

LCD Power Supply	Static Mode	1/3 Bias	1/4 Bias
V_{LC4}	V_{LCD}	–	V_{LCD}
V_{LC3}	–	V_{LCD}	3/4 V_{LCD}
V_{LC2}	–	2/3 V_{LCD}	2/4 V_{LCD}
V_{LC1}	–	1/3 V_{LCD}	1/4 V_{LCD}
V_{SS}	0 V	0 V	0 V

NOTE: The LCD panel display may be deteriorated if a DC voltage is applied that lies between the common and segment signal voltage. Therefore, always drive the LCD panel with AC voltage.

LCD SEG/COM SIGNALS

The 24 LCD segment signal pins are connected to corresponding display RAM locations at 00H-17H. Bits 0-7 of the display RAM are synchronized with the common signal output pins COM0, ... , and COM7.

When the bit value of a display RAM location is "1", a select signal is sent to the corresponding segment pin. When the display bit is "0", a 'no-select' signal is sent to the corresponding segment pin. Each bias has select and no-select signals.

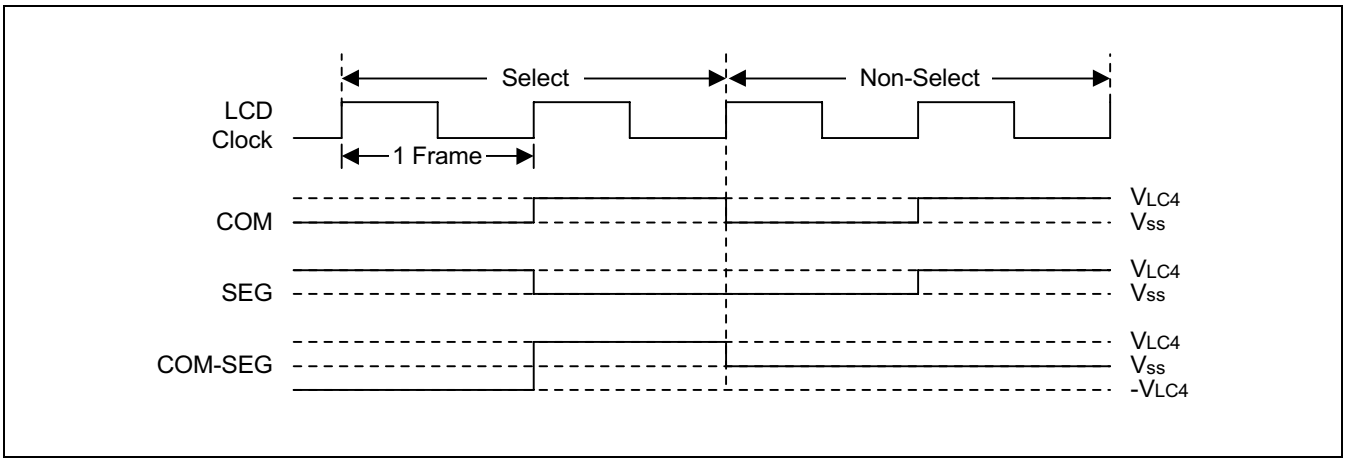

Figure 14-6. Select/No-Select Bias Signals in Static Display Mode

LCD VOLTAGE DRIVING METHOD

By Voltage Booster

For run the voltage booster

— Make enable the watch timer for $f_{booster}$

— Set LCON.1-.0 to "01" for make enable voltage booster

— Recommendable capacitance value is 0.1 uF (CA/B, C1, C2, C3, C4)

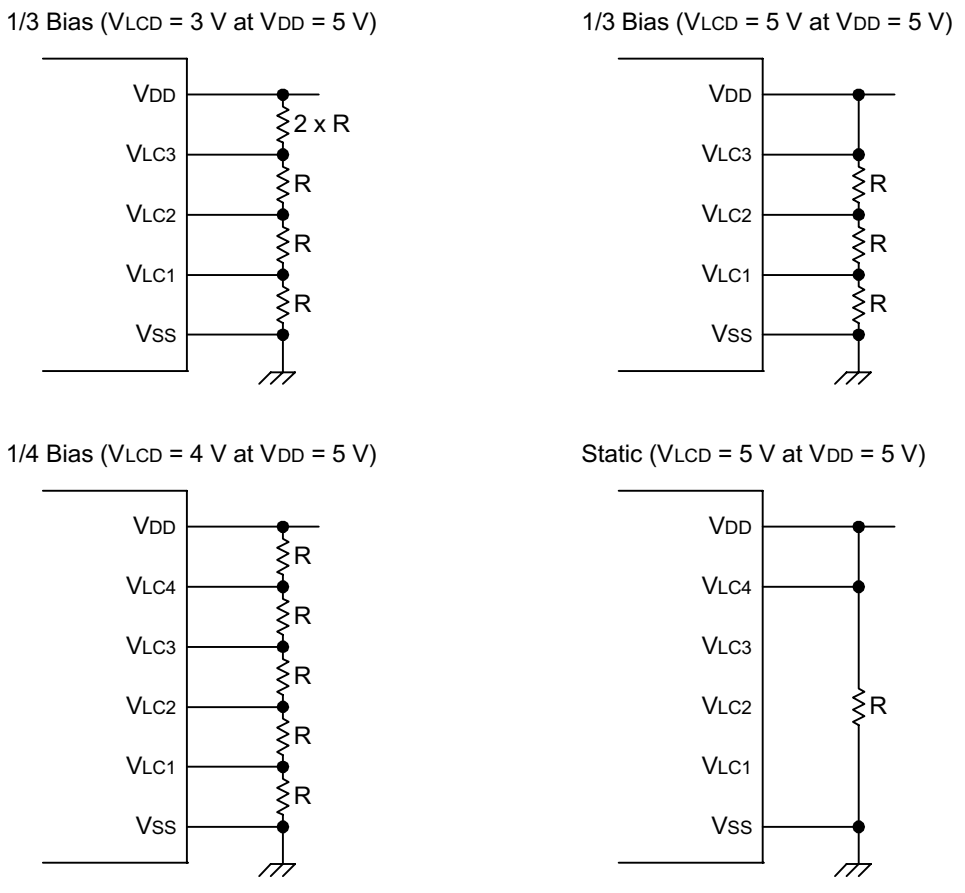
By Voltage Dividing Resistors (Externally)

For make external voltage dividing resistors

— Set LCON.1-.0 to "1x" for make disable voltage booster

— Make floating the CA and CB pin

— Recommendable R = 100 Kohm



NOTE: About pin connection of CAP bias, refer to chapter 16, voltage booster.

NOTES

15 10-BIT ANALOG-TO-DIGITAL CONVERTER

OVERVIEW

The 10-bit A/D converter (ADC) module uses successive approximation logic to convert analog levels entering at one of the eight input channels to equivalent 10-bit digital values. The analog input level must lie between the AV_{REF} and AV_{SS} values. The A/D converter has the following components:

— Analog comparator with successive approximation logic

— D/A converter logic (resistor string type)

— ADC control register (ADCON)

— AD interrupt register(ADINT)

— Eight multiplexed analog data input pins (AD0 - AD7) , alternately digital data I/O port

— 10-bit A/D conversion data output register (ADDATAH/L)

— AV_{REF} and AV_{SS} pins, AV_{SS} is internally connected to V_{SS}

FUNCTION DESCRIPTION

To initiate an analog-to-digital conversion procedure, at the first you must set port control register(P1CONH/L) for AD analog input. And you write the channel selection data in the A/D converter control register ADCON.4-.6 to select one of the eight analog input pins (AD0-7) and set the conversion start or enable bit, ADCON.0. The read-write ADCON register is located in set 1, bank 1, at address F7H. The unused pin can be used for normal I/O.

During a normal conversion, ADC logic initially sets the successive approximation register to 200H (the approximate half-way point of an 10-bit register). This register is then updated automatically during each conversion step. The successive approximation block performs 10-bit conversions for one input channel at a time. You can dynamically select different channels by manipulating the channel selection bit value (ADCON.6 - 4) in the ADCON register. To start the A/D conversion, you should set the enable bit, ADCON.0. When a conversion is completed, ADINT.0, the end-of-conversion(EOC) bit or pending bit is automatically set to 1 and the result is dumped into the ADDATAH/L register where it can be read. The A/D converter then enters an idle state. Remember to read the contents of ADDATAH/L before another conversion starts. Otherwise, the previous result will be overwritten by the next conversion result.

NOTE

Because the A/D converter has no sample-and-hold circuitry, it is very important that fluctuation in the analog level at the AD0-AD7 input pins during a conversion procedure be kept to an absolute minimum. Any change in the input level, perhaps due to noise, will invalidate the result. **If the chip enters to STOP or IDLE mode in conversion process, there will be a leakage current path in A/D block**. You must use STOP or IDLE mode after ADC operation is finished.

CONVERSION TIMING

The A/D conversion process requires 4 steps (4 clock edges) to convert each bit and 10 clocks to set-up A/D conversion. Therefore, total of 50 clocks are required to complete an 10-bit conversion: When Fxx/8 is selected for conversion clock with an 8 MHz fxx clock frequency, one clock cycle is 1 us. Each bit conversion requires 4 clocks, the conversion rate is calculated as follows:

4 clocks/bit × 10 bits + set-up time = 50 clocks, 50 clock × 1us = 50 us at 1 MHz

A/D CONVERTER CONTROL REGISTER (ADCON)

The A/D converter control register, ADCON, is located at address F7H in set 1, bank 0. It has three functions:

— Analog input pin selection (bits 4, 5, and 6)

— ADC interrupt enable (bit 3)

— A/D operation start or enable (bit 0)

— A/D conversion speed selection (bit 1,2)

After a reset, the start bit is turned off. You can select only one analog input channel at a time. Other analog input pins (ADC0–ADC7) can be selected dynamically by manipulating the ADCON.4–6 bits. And the pins not used for analog input can be used for normal I/O function.

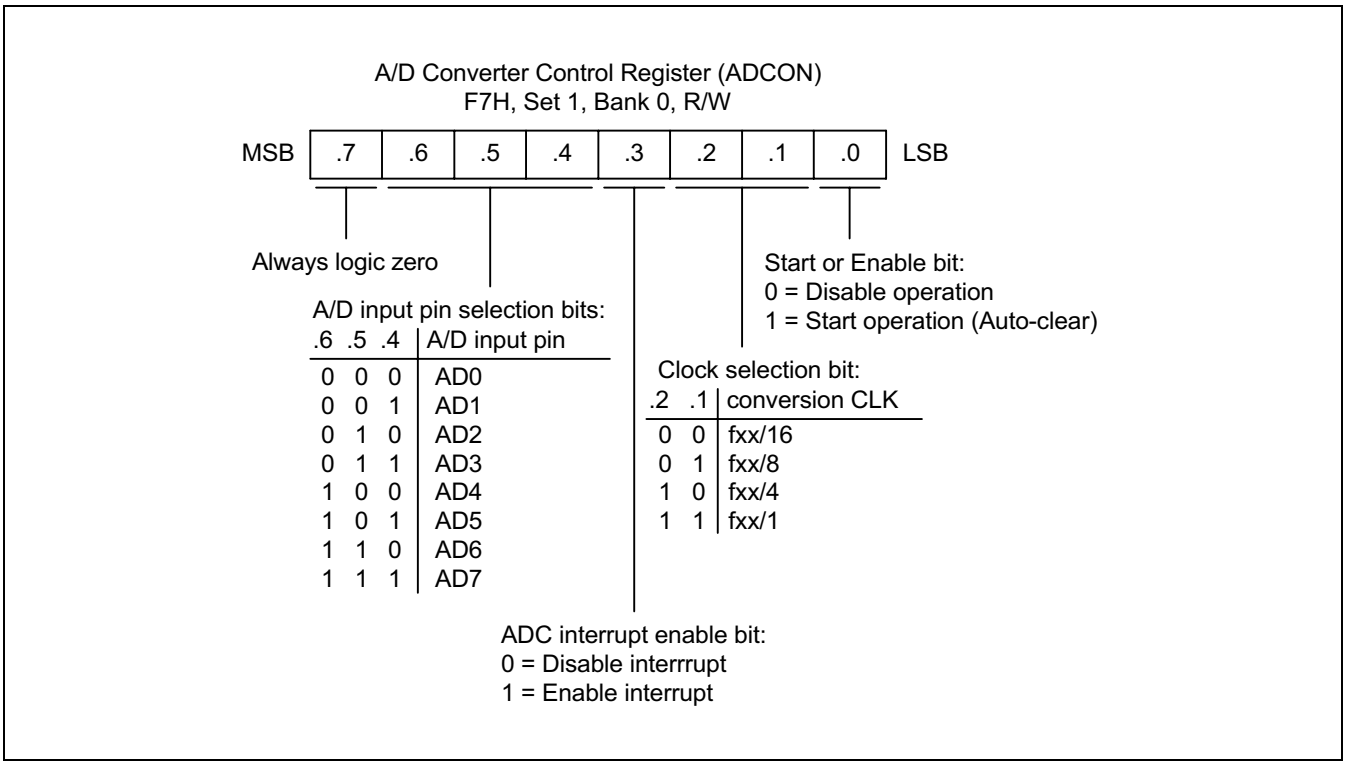

Figure 15-1. A/D Converter Control Register (ADCON)

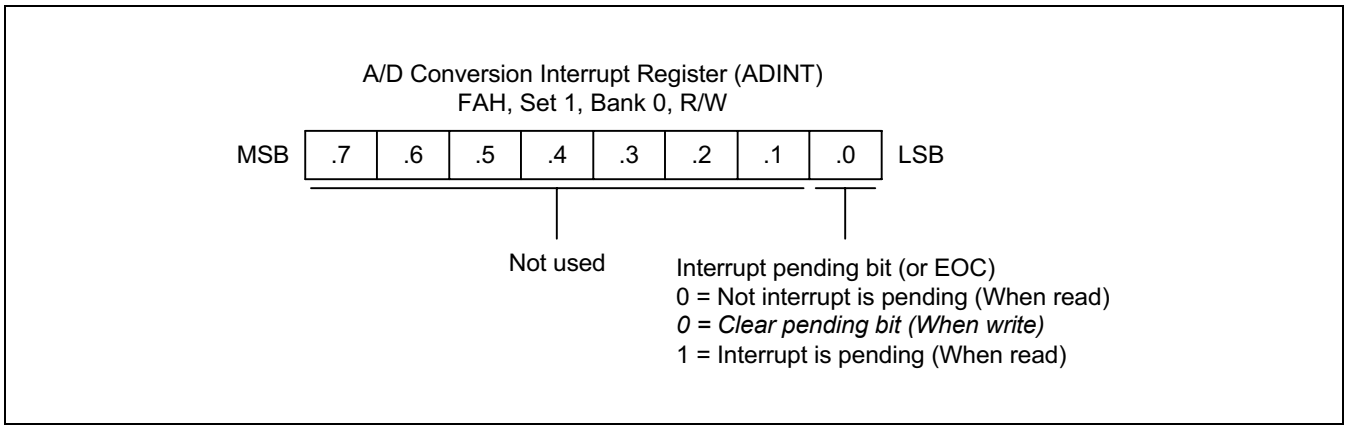

Figure 15-2. A/D Conversion Interrupt Register (ADINT)

Figure 15-3. A/D Converter Data Register (ADDATAH/L)

INTERNAL REFERENCE VOLTAGE LEVELS

In the ADC function block, the analog input voltage level is compared to the reference voltage. The analog input level must remain within the range AV_{SS} to AV_{REF} (usually, AV_{REF} = V_{DD}).

Different reference voltage levels are generated internally along the resistor tree during the analog conversion process for each conversion step. The reference voltage level for the first conversion bit is always 1/2 AV_{REF}.

16 VOLTAGE BOOSTER

OVERVIEW

This voltage booster works for the power control of LCD: generates 4 x $V_R(V_{LC1})$, 3 x $V_R(V_{LC1})$, 2 x $V_R(V_{LC1})$, 1 x $V_R(V_{LC1})$. This voltage booster allows low voltage operation of LCD display with high quality. This voltage booster circuit provides constant LCD contrast level even though battery power supply was lowered.

This voltage booster include voltage regulator, and voltage charge/pump circuit.

FUNCTION DESCRIPTION

The voltage booster has built for driving the LCD. The voltage booster provides the capability of directly connecting an LCD panel to the MCU without having to separately generate and supply the higher voltages required by the LCD panel. The voltage booster operates on an internally generated and regulated LCD system voltage and generates a doubled , a tripled and a four-fold voltage levels to supply the LCD drive circuit. External capacitor are required to complete the power supply circuits.

The Vdd power line is regulated to get the $V_{LC1}(V_R)$ level, which become a base level for voltage boosting. Then a doubled ,a tripled and a four-fold voltage will be made by capacitor charge and pump circuit.

BLOCK DIAGRAM

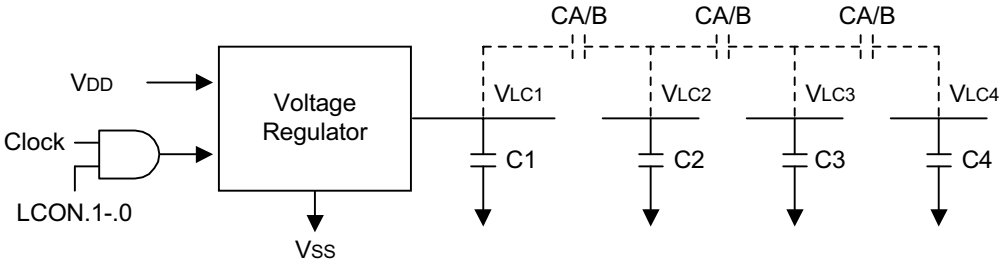

Figure 16-1. Voltage Booster Block Diagram

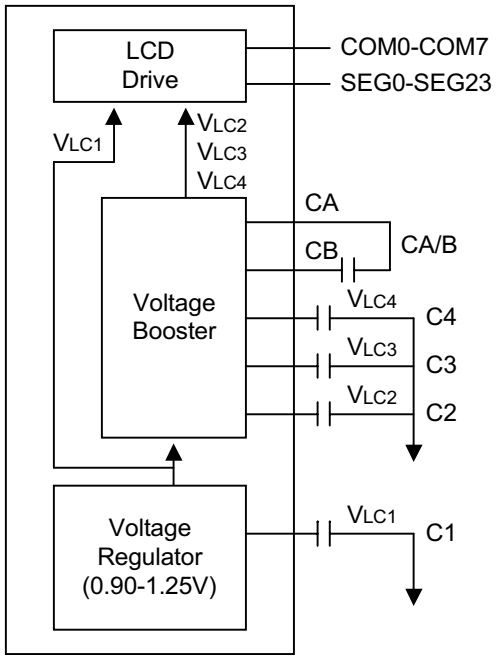

NOTE: In case of 1/4 bias and static mode, pins must be connected as above but in case of 1/3 bias mode V_{LC4} pin must be opened.

Figure 16-2. Pin Connection Example

Table 16-1. Voltage Booster Absolute Maximum Ratings

Parameter	Symbol	Value	Unit
Supply Voltage	V_{DD}	-0.3 – 6.5	V
Operating Temperature Range	T_{OPR}	-40 – +85	°C
Storage Temperature Range	T_{STG}	-65 – +150	°C

Table 16-2. Voltage Booster Electrical Characteristics

(T_A = 25 °C, V_{DD} = 2.0 V to 5.5 V, V_{SS} = 0 V)

Parameter	Symbol	Test Conditions	Min	Typ	Max	Unit
Operating Voltage	V_{DD}		2.0	–	5.5	V
Regulated Voltage	V_{LC1}	Connect 1 MΩ load between V_{SS} and V_{LC1}	0.85	1.05	1.30	
Booster Voltage	V_{LC2}	Connect 1 MΩ load between V_{SS} and V_{LC2}	$2V_{LC1}$ x 0.9	–	$2V_{LC1}$ x 1.1	
	V_{LC3}	Connect 1 MΩ load between V_{SS} and V_{LC3}	$3V_{LC1}$ x 0.9	–	$3V_{LC1}$ x 1.1	
	V_{LC4}	Connect 1 MΩ load between V_{SS} and V_{LC4}	$4V_{LC1}$ x 0.9	–	$4V_{LC1}$ x 1.1	

NOTES

17 VOLTAGE LEVEL DETECTOR

OVERVIEW

The S3C8238/C8235/F8235 micro-controller has a built-in VLD(Voltage Level Detector) circuit which allows detection of power voltage drop through software. Turning the VLD operation on and off can be controlled by software. Because the IC consumes a large amount of current during VLD operation. It is recommended that the VLD operation should be kept OFF unless it is necessary. Also the VLD criteria voltage can be set by the software. The criteria voltage can be set by matching to one of the 3 kinds of voltage 2.4V, 3.3V or 4.5V (VDD reference voltage).

The VLD block works only when VLDCON.2 is set. If VDD level is lower than the reference voltage selected with VLDCON.1-.0, VLDCON.3 will be set. If VDD level is higher, VLDCON.3 will be cleared. Please do not operate the VLD block for minimize power current consumption.

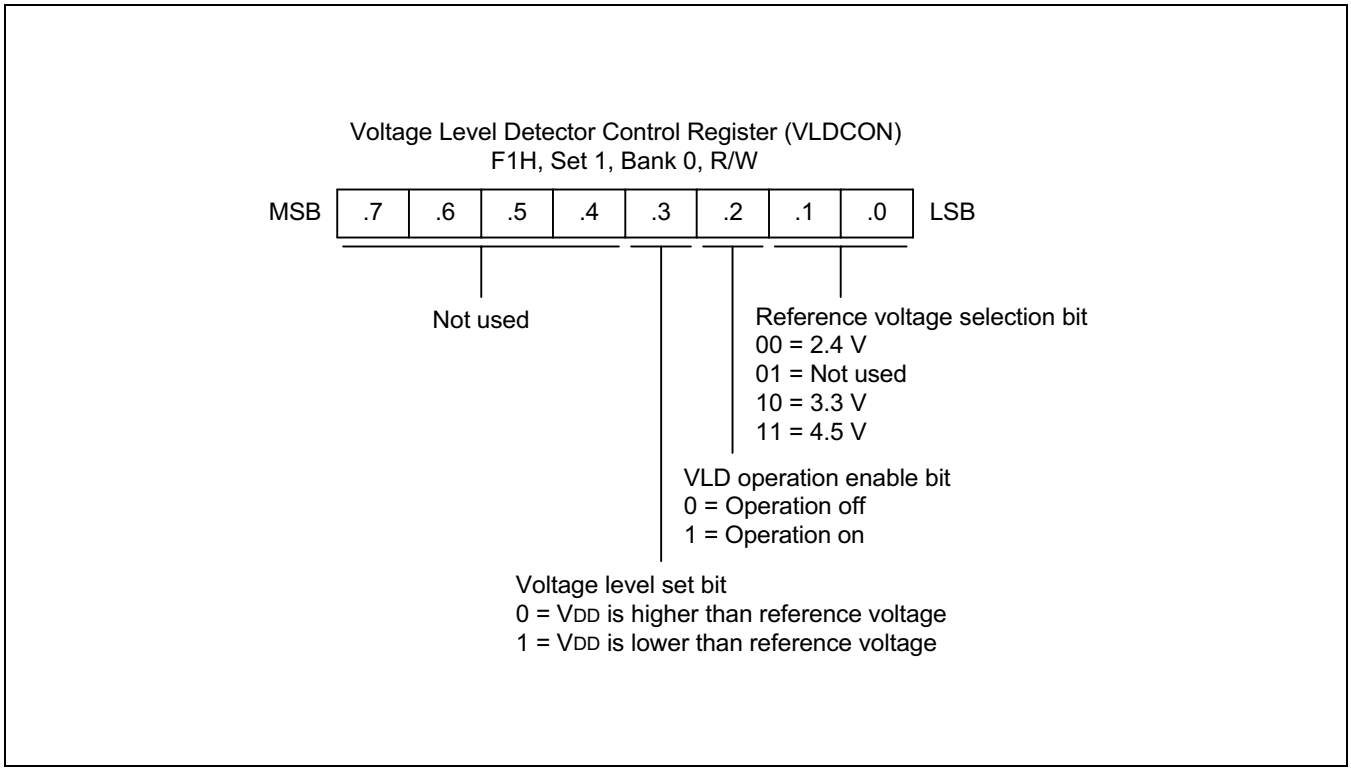

Figure 17-1. VLD Control Register (VLDCON)

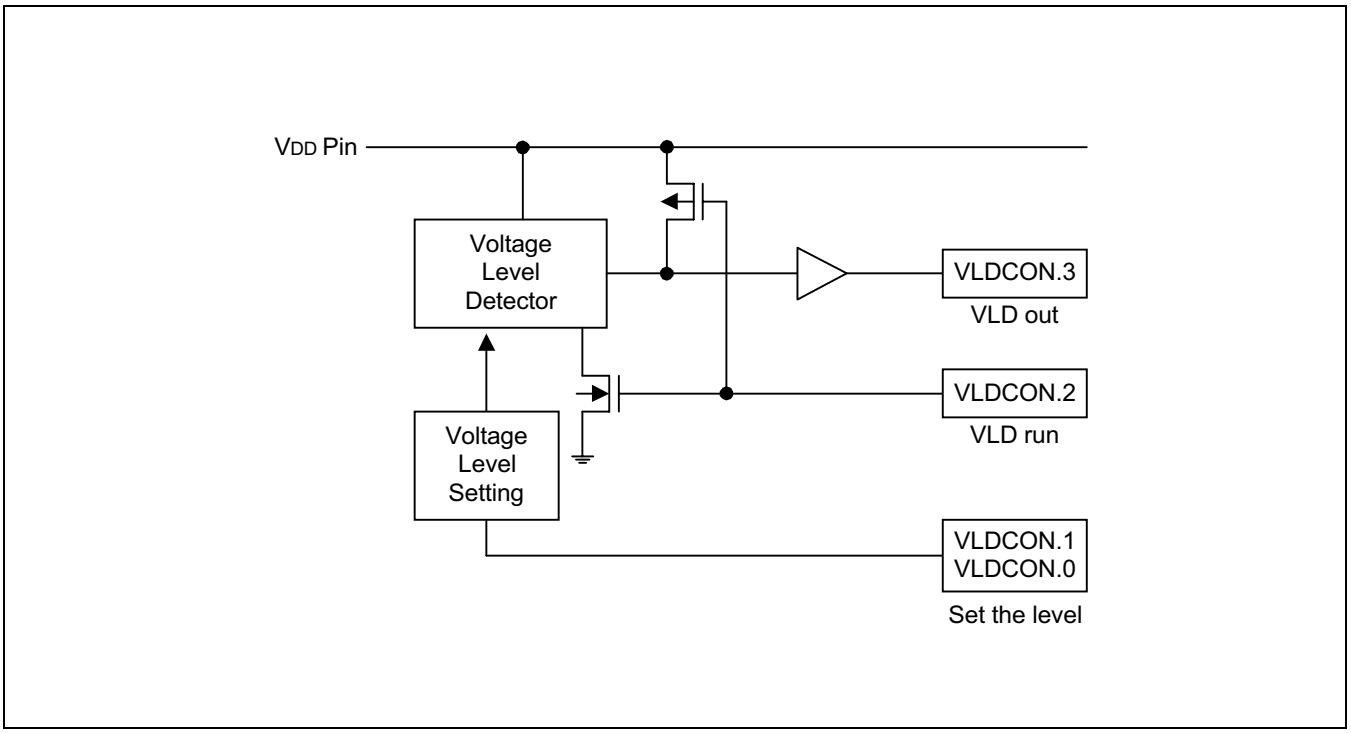

Figure 17-2. Block Diagram for Voltage Level Detect

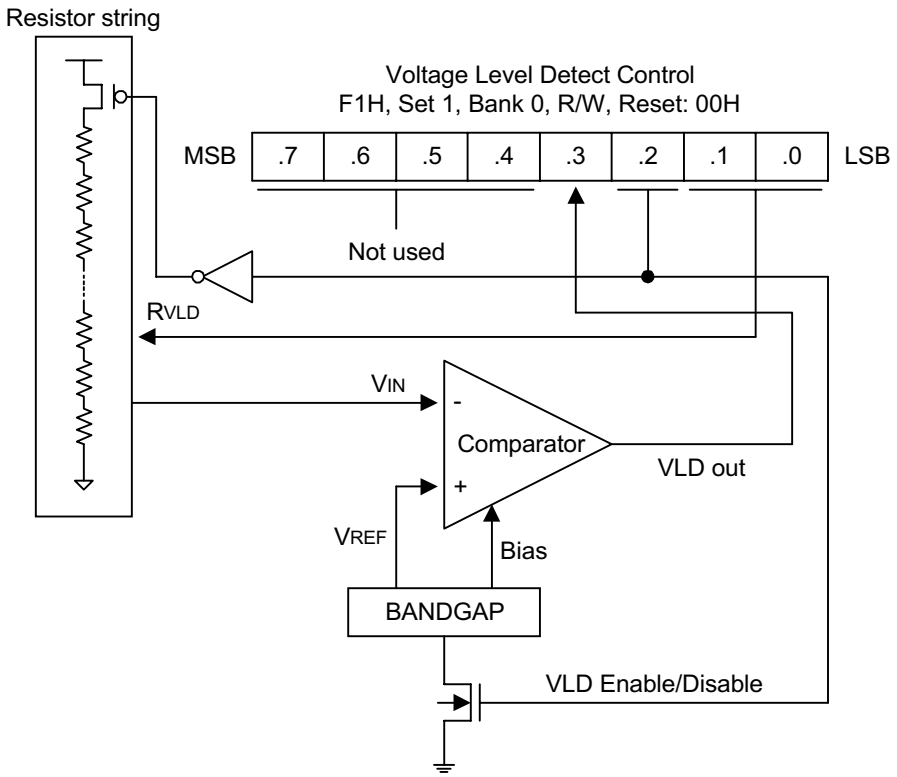
VOLTAGE LEVEL DETECTOR CONTROL REGISTER (VLDCON)

The bit 2 of VLDCON controls to run or disable the operation of Voltage level detector. Basically this V_{VLD} is set as 2.4 V by system reset and it can be changed in 3 kinds voltages by selecting Voltage Level Detector Control register(VLDCON). When you write 2 bit data value to VLDCON, an established resistor string is selected and the V_{VLD} is fixed in accordance with this resistor. Table 17-1 shows specific V_{VLD} of 3 levels.



NOTE: The reset value of VLDCON is #00H

Figure 17-2. Voltage Level Detect Circuit and Control Register

Table 17-1. VLDCON Value and Detection Level

VLDCON .1-.0	V_{VLD}
0 0	2.4 V
0 1	Not used
1 0	3.3 V
1 1	4.5 V

NOTE: Where, VLDCON reset value: 0H

Table 17-2. Characteristics of Voltage Level Detect Circuit

(T_A = 25 °C)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Operating Voltage	V_{DDVLD}		1.5	–	5.5	V
Detection Voltage	V_{VLD}	VLDCON.1.0 = 00b	2.0	2.4	2.8	
		VLDCON.1.0 = 01b	Not used			
		VLDCON.1.0 = 10b	2.9	3.3	3.7	
		VLDCON.1.0 = 11b	4.1	4.5	4.9	
Current consumption	I_{VLD}	VLD on V_{DD} = 5.5 V	–	10	20	uA
		V_{DD} = 3.0 V		5	10	
		V_{DD} = 2.0 V		4	8	
Hysteresis Voltage (Slew Rate of VLD)	ΔV	VLDCON.1.0 = 00b	–	10	100	mV
		VLDCON.1.0 = 11b

18 PATTERN GENERATION MODULE

OVERVIEW

PATTERN GNERATION FLOW

You can output up to 8-bit through P1.4-P1.7 and P4.0-P4.3 by tracing the following sequence. First of all, you have to change the PGDATA into what you want to output. And then you have to set the PGCON to enable the pattern generation module and select the triggering signal. From now, bits of PGDATA are on the P1.4-P1.7 and P4.0-P4.3 whenever the selected triggering signal happens.

19 ELECTRICAL DATA

OVERVIEW

In this chapter, S3C8238/C8235 electrical characteristics are presented in tables and graphs. The information is arranged in the following order:

— Absolute maximum ratings
— Input/output capacitance
— D.C. electrical characteristics
— A.C. electrical characteristics
— Oscillation characteristics
— Oscillation stabilization time
— Data retention supply voltage in stop mode
— A/D converter electrical characteristics

Table 19-1. Absolute Maximum Ratings

(T_A= 25 °C)

Parameter	Symbol	Conditions	Rating	Unit
Supply voltage	V_{DD}		– 0.3 to +6.5	V
Input voltage	V_I		– 0.3 to V_{DD} + 0.3	
Output voltage	V_O		– 0.3 to V_{DD} + 0.3	
Output current high	I_{OH}	One I/O pin active	– 18	mA
		All I/O pins active	– 60	
Output current low	I_{OL}	One I/O pin active	+30	
		Total pin current for port	+100	
Operating temperature	T_A		– 40 to + 85	°C
Storage temperature	T_{STG}		– 65 to + 150	

Table 19-2. D.C. Electrical Characteristics

(T_A = -40 °C to + 85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Operating voltage	V_{DD}	f_{CPU} = 10 MHz	2.7	–	5.5	V
		f_{CPU} = 4 MHz	2.0		5.5	
Input high voltage	V_{IH1}	All input pins except V_{IH2}	0.8 V_{DD}		V_{DD}	
	V_{IH2}	X_{IN}, XT_{IN}	V_{DD}-0.1			
Input low voltage	V_{IL1}	All input pins except V_{IL2}	–		0.2 V_{DD}	
	V_{IL2}	X_{IN}, XT_{IN}			0.1	

NOTE: P0 and P3 are schmitt trigger ports.

Table 19-2. D.C. Electrical Characteristics (Continued)

(T_A = -40 °C to + 85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Output high voltage	V_{OH1}	V_{DD} = 2.4 V; I_{OH} = -4 mA Port 0.4 only	V_{DD} - 0.7	V_{DD} - 0.3	–	V
	V_{OH2}	V_{DD} = 5 V; I_{OH} = -4 mA Port 3	V_{DD} - 1.0	–	–	
	V_{OH3}	V_{DD} = 5 V; I_{OH} = -1 mA All output pins except P0.4,P3	V_{DD} - 1.0	–	–	
Output low voltage	V_{OL1}	V_{DD} = 2.4 V; I_{OL} = 12 mA P0.4 only		0.3	0.5	
	V_{OL2}	V_{DD} = 5 V; I_{OL} = 15 mA P3		0.4	2.0	
	V_{OL3}	V_{DD} = 5 V; I_{OL} = 4 mA All output pins except P0.4,P3	–	0.4	2.0	
Input high leakage current	I_{LIH1}	V_{IN} = V_{DD} All input pins except I_{LIH2}	–	–	3	µA
	I_{LIH2}	V_{IN} = V_{DD}, X_{IN}, XT_{IN}			20	
Input low leakage current	I_{LIL1}	V_{IN} = 0 V All input pins except I_{LIL2}	–	–	-3	
	I_{LIL2}	V_{IN} = 0 V, X_{IN}, XT_{IN}			-20	
Output high leakage current	I_{LOH}	V_{OUT} = V_{DD} All I/O pins and Output pins	–	–	3	
Output low leakage current	I_{LOL}	V_{OUT} = 0 V All I/O pins and Output pins	–	–	-3	
Oscillator feed back resistors	R_{OSC1}	V_{DD} = 5.0 V T_A = 25 °C X_{IN} = V_{DD}, X_{OUT} = 0 V	800	1000	1200	kΩ
Pull-up resistor	R_{L1}	V_{IN} = 0 V; V_{DD} = 5 V ±10 % Port 0,1,2,4 T_A = 25°C	25	50	100	
	R_{L2}	V_{IN} = 0 V; V_{DD} = 5 V ±10% T_A=25 °C, RESET only	110	210	310	
COM output voltage deviation	V_{DC}	V_{DD} = V_{LC3} = 4 V (V_{LC3}-COMi) IO = ± 15 p-µA (i = 0-3)	–	± 60	± 200	mV
SEG output voltage deviation	V_{DS}	V_{DD} = V_{LC3} = 4 V (V_{LC3}-SEGi) IO = ± 15 p-µA (i = 0-23)	–	± 60	± 200	

Table 19-2. D.C. Electrical Characteristics (Concluded)

(T_A = -40 °C to + 85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Supply current (1)	I_{DD1} (2)	V_{DD} = 5 V ± 10 % 10 MHz crystal oscillator	–	12	25	mA
		4 MHz crystal oscillator		4	10	
		V_{DD} = 3 V ± 10 % 10 MHz crystal oscillator		3	8	
		4 MHz crystal oscillator		1	5	
	I_{DD2}	Idle mode: V_{DD} = 5 V ± 10 % 10 MHz crystal oscillator		3	10	
		4 MHz crystal oscillator		1.5	4	
		Idle mode: V_{DD} = 3 V± 10 % 10 MHz crystal oscillator		1.2	3	
		4 MHz crystal oscillator		1.0	2.0	
	I_{DD3}	Sub operating: main-osc stop V_{DD} = 3 V ± 10 % 32768 Hz crystal oscillator		40	80	µA
	I_{DD4}	Sub idle mode: main osc stop V_{DD} = 3 V ± 10 % 32768 Hz crystal oscillator		7	14	
	I_{DD5}	Main stop mode : sub-osc stop V_{DD} = 5 V ± 10 %		1	3	
		V_{DD} = 3 V ± 10 %		0.5	2	

NOTES:

1. Supply current does not include current drawn through internal pull-up resistors or external output current loads.
2. I_{DD1} and I_{DD2} include a power consumption of subsystem oscillator.
3. I_{DD3} and I_{DD4} are the current when the main system clock oscillation stop and the subsystem clock is used.
   And they does not include the LCD and Voltage booster and voltage level detector current.
4. I_{DD5} is the current when the main and subsystem clock oscillation stop.
5. Voltage booster's operating voltage rage is 2.0V to 5.5V.
6. If you use LVR module, supply current increase. (refer to Table 19-12)

Table 19-3. A.C. Electrical Characteristics

(T_A = -40 °C to +85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Interrupt input high, low width (P0.0–P0.7)	t_{INTH}, t_{INTL}	P0.0–P0.7, V_{DD} = 5 V	200	–	–	ns
RESET input low width	t_{RSL}	V_{DD} = 5 V	1.5	–	–	µS

NOTE: User must keep more large value then min value.

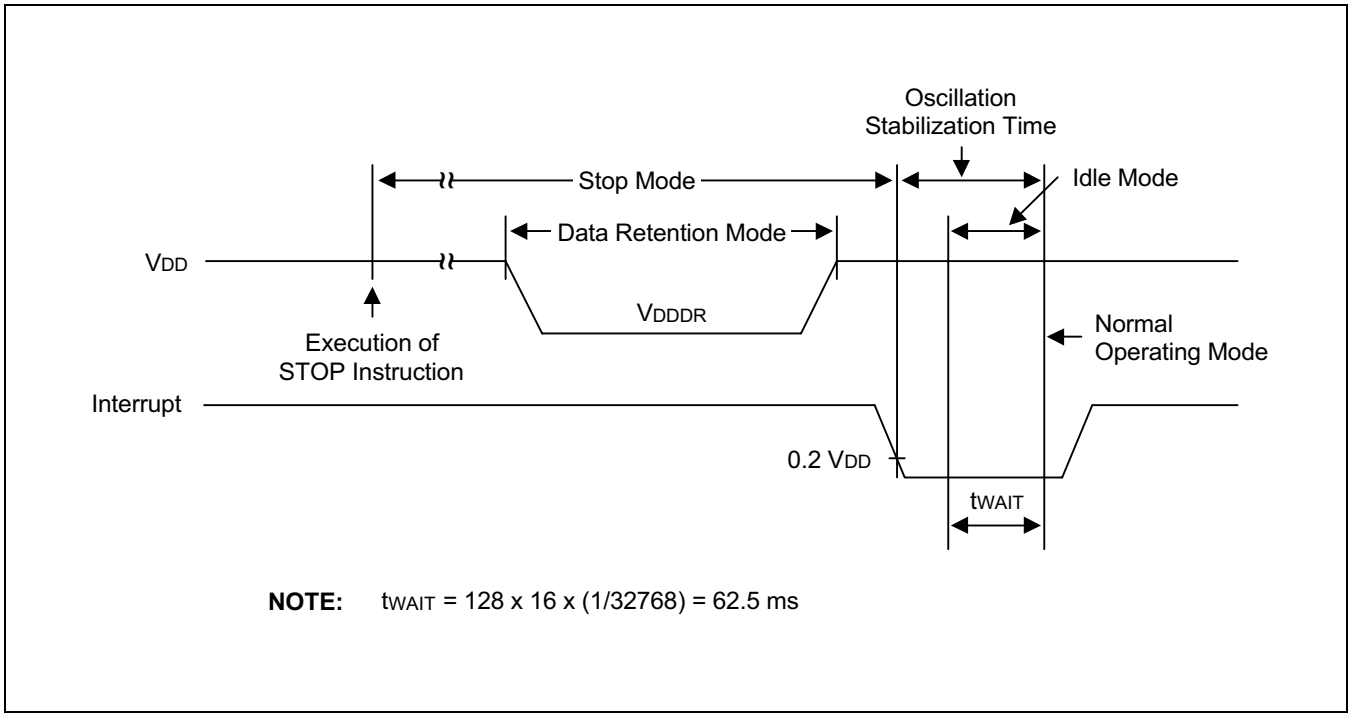

Figure 19-5. Stop Mode(sub) Release Timing Initiated by Interrupts

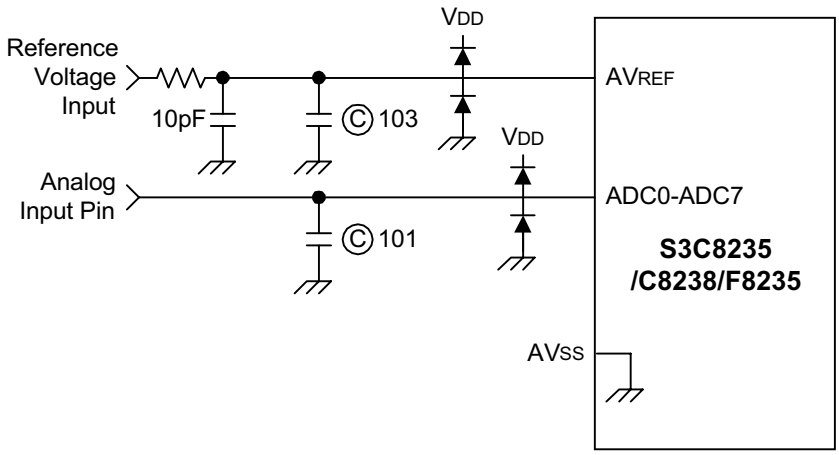
Table 19-6. A/D Converter Electrical Characteristics

(T_A = - 40 °C to +85 °C, V_{DD} = 2.0 V to 5.5 V, V_{SS} = 0 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Resolution			–	10	–	bit
Total accuracy		V_{DD} = 5.12 V	–	–	±3	LSB
Integral Linearity Error	ILE	AV_{REF} = 5.12V	–	–	±2	
Differential Linearity Error	DLE	AV_{SS} = 0 V CPU clock = 10 MHz	–	–	±1	
Offset Error of Top	EOT		–	±1	±3	
Offset Error of Bottom	EOB		–	±0.5	±2	
Conversion time (1)	T_{CON}	10-bit resolution 50 x fxx/4, fxx = 10MHz	20	–	–	μS
Analog input voltage	V_{IAN}	–	AV_{SS}	–	AV_{REF}	V
Analog input impedance	R_{AN}	–	2	1000	–	MΩ
Analog reference voltage	AV_{REF}	–	2.5	–	V_{DD}	V
Analog ground	AV_{SS}	–	V_{SS}	–	V_{SS} +0.3	
Analog input current	I_{ADIN}	AV_{REF} = V_{DD} = 5V	–	–	10	μA
Analog block current (2)	I_{ADC}	AV_{REF} = V_{DD} = 5V	–	1	3	mA
		AV_{REF} = V_{DD} = 3V		0.5	1.5	
		AV_{REF} = V_{DD} = 5V When Power Down mode		100	500	nA

NOTES:

1. 'Conversion time' is the time required from the moment a conversion operation starts until it ends.
2. I_{ADC} is an operating current during A/D conversion.



NOTE: The symbol 'R' signifies an offset resistor with a value of from 50 to 100.
If this resistor is omitted, the absolute accuracy will be maximum of 3 LSBs.

Figure 19-6. Recommended A/D Converter Circuit for Highest Absolute Accuracy

Table 19-7. Main Oscillator Frequency (f_{OSC1})

(T_A = -40 °C to +85 °C, V_{DD} = 2.0 V to 5.5 V)

Oscillator	Clock Circuit	Test Condition	Min	Typ	Max	Unit
Crystal		Crystal oscillation frequency	1	–	10	MHz
Ceramic		Ceramic oscillation frequency	1	–	10	
External clock		X_{IN} input frequency	1	–	10	
RC		r = 35 KΩ, V_{DD} = 5 V		2		

Table 19-8. Main Oscillator Clock Stabilization Time (t_{ST1})

(T_A = -40 °C to +85 °C, V_{DD} = 2.0 V to 5.5 V)

Oscillator	Test Condition	Min	Typ	Max	Unit
Crystal	V_{DD} = 4.5 V to 5.5 V	–	–	10	ms
	V_{DD} = 2.0 V to 4.5 V			30	
Ceramic	Stabilization occurs when V_{DD} is equal to the minimum oscillator voltage range.	–	–	4	
External clock	X_{IN} input high and low level width (t_{XH}, t_{XL})	50	–	–	ns

NOTE: Oscillation stabilization time (t_{ST1}) is the time required for the CPU clock to return to its normal oscillation frequency after a power-on occurs, or when Stop mode is ended by a RESET signal.

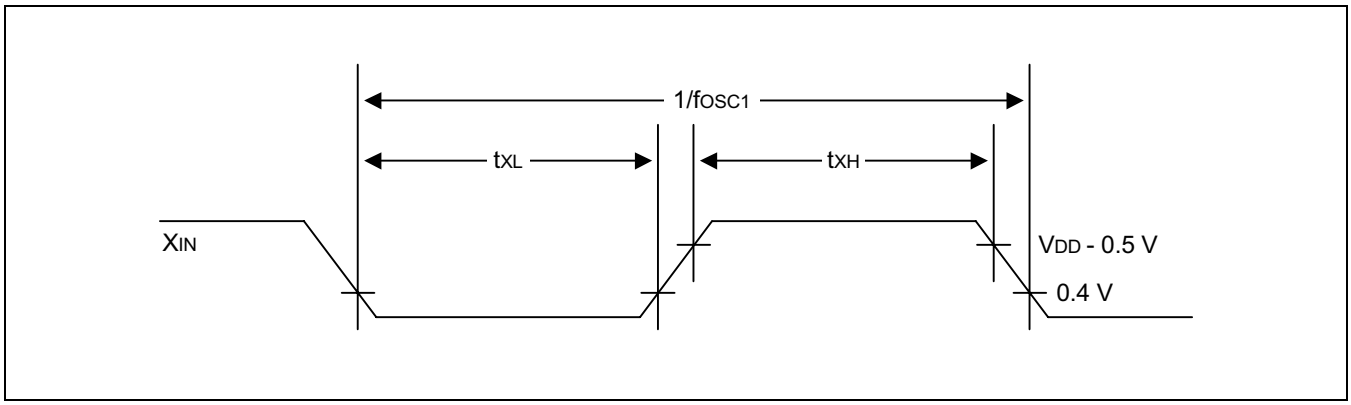


Figure 19-7. Clock Timing Measurement at X_{IN}

Table 19-9. Sub Oscillator Frequency (f_{OSC2})

(T_A = -40 °C + 85 °C, V_{DD} = 2.0 V to 5.5 V)

Oscillator	Clock Circuit	Test Condition	Min	Typ	Max	Unit
Crystal		C1 = 33 pF, C2 = 33 pF	32	32.768	35	kHz

Table 19-10. Sub Oscillator(crystal) Stabilization Time (t_{ST2})

(T_A = 25 °C, V_{DD} = 2.0 V to 5.5 V))

Test Condition	Min	Typ	Max	Unit
V_{DD} = 4.5 V to 5.5 V	–	250	500	ms
V_{DD} = 2.0 V to 4.5 V	–	–	2	s

NOTE: Oscillation stabilization time (t_{ST2}) is the time required for the CPU return to its normal operation when Stop mode is released by interrupts.

Table 19-11. Analog Circuit Characteristics and Consumed Current

(T_A = – 40 °C + 85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions		Min	Typ	Max	Unit
Liquid Crystal drive Voltage	V_{LC1}	Connect a 1MΩ Load resistance Between V_{SS} and V_{LC1}(note) (No pannel load)	LCON.7-.5 = 0	Typ. x 0.9	0.90	Typ. x 1.1	V
			LCON.7-.5 = 1		0.95		
			LCON.7-.5 = 2		1.00		
			LCON.7-.5 = 3		1.05		
			LCON.7-.5 = 4		1.10		
			LCON.7-.5 = 5		1.15		
			LCON.7-.5 = 6		1.20		
			LCON.7-.5 = 7		1.25		
	V_{LC2}	Connect a 1Mohm load resistance between V_{SS} and V_{LC2}(note) (No panel load)		2 x V_{LC1} x 0.9	–	2 x V_{LC1} x 1.1	
	V_{LC3}	Connect a 1Mohm load resistance between V_{SS} and V_{LC3}(note) (No panel load)		3 x V_{LC1} x 0.9	–	3 x V_{LC1} x 1.1	
	V_{LC4}	Connect a 1Mohm load resistance between V_{SS} and V_{LC4}(note) (No panel load)		4 x V_{LC1} x 0.9	–	4 x V_{LC1} x 1.1

20 MECHANICAL DATA

OVERVIEW

The S3C8238/C8235 microcontroller is currently available in 64-SDIP, 64-QFP, 64-LQFP package.

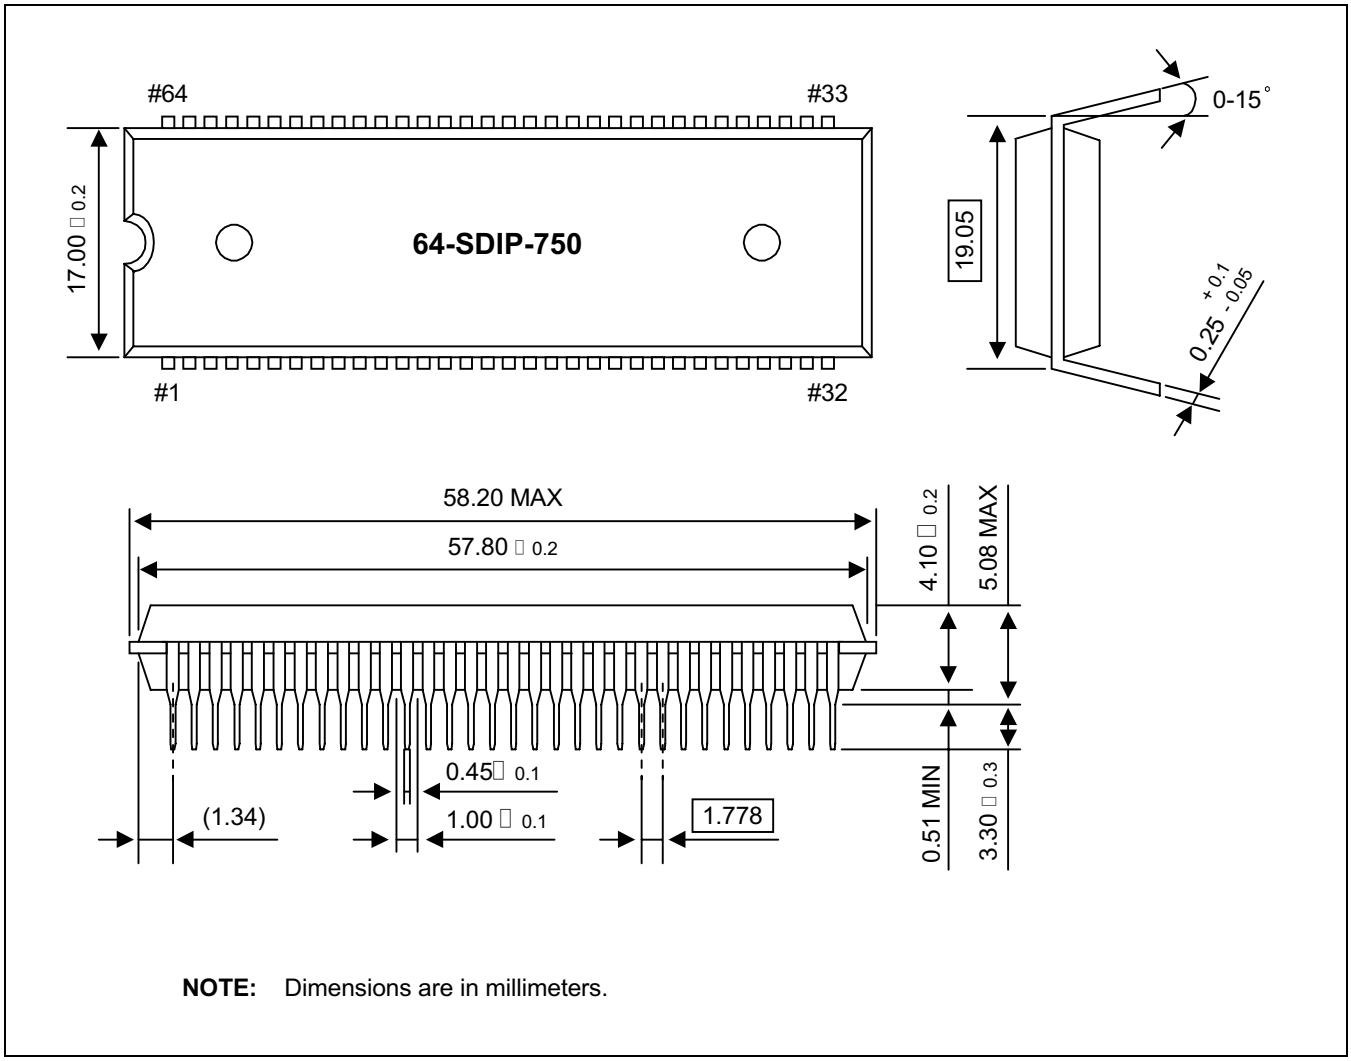

Figure 20-1. 64-SDIP-750 Package Dimensions

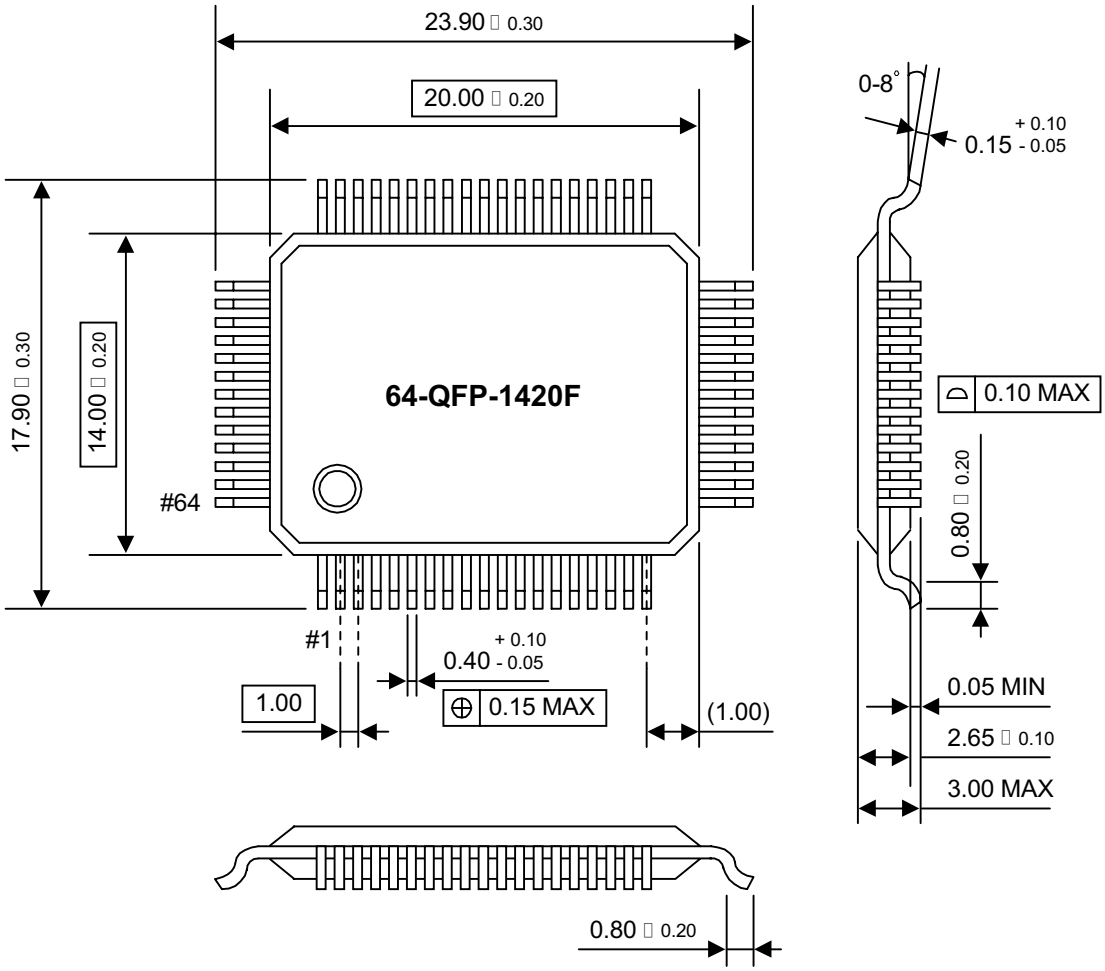

Figure 20-2. 64-QFP-1420F Package Dimensions

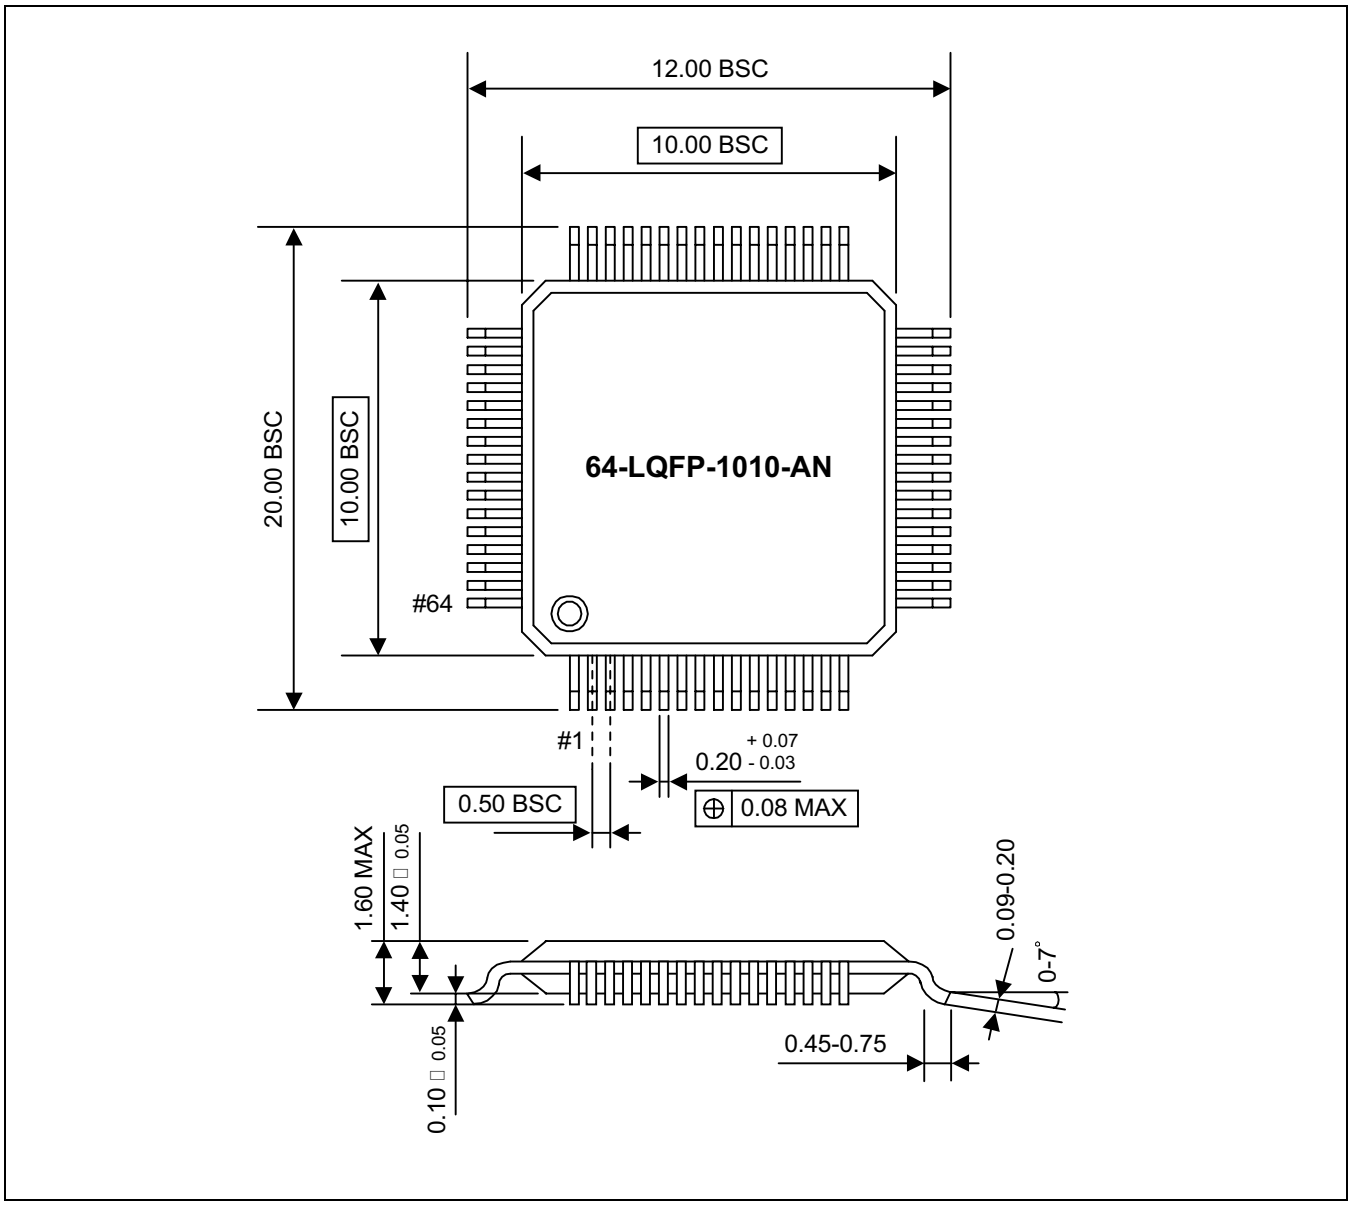

Figure 20-3. 64-LQFP-1010-AN Package Dimensions

NOTES

21 S3F8235 FLASH MCU

OVERVIEW

The S3F8235 single-chip CMOS microcontroller is the Flash MCU version of the S3C8235 microcontroller. It has an on-chip Flash MCU ROM instead of a masked ROM. The Flash ROM is accessed by serial data format.

The S3F8235 is fully compatible with the S3C8235, both in function and in pin configuration. Because of its simple programming requirements, the S3F8235 is ideal as an evaluation chip for the S3C8235.

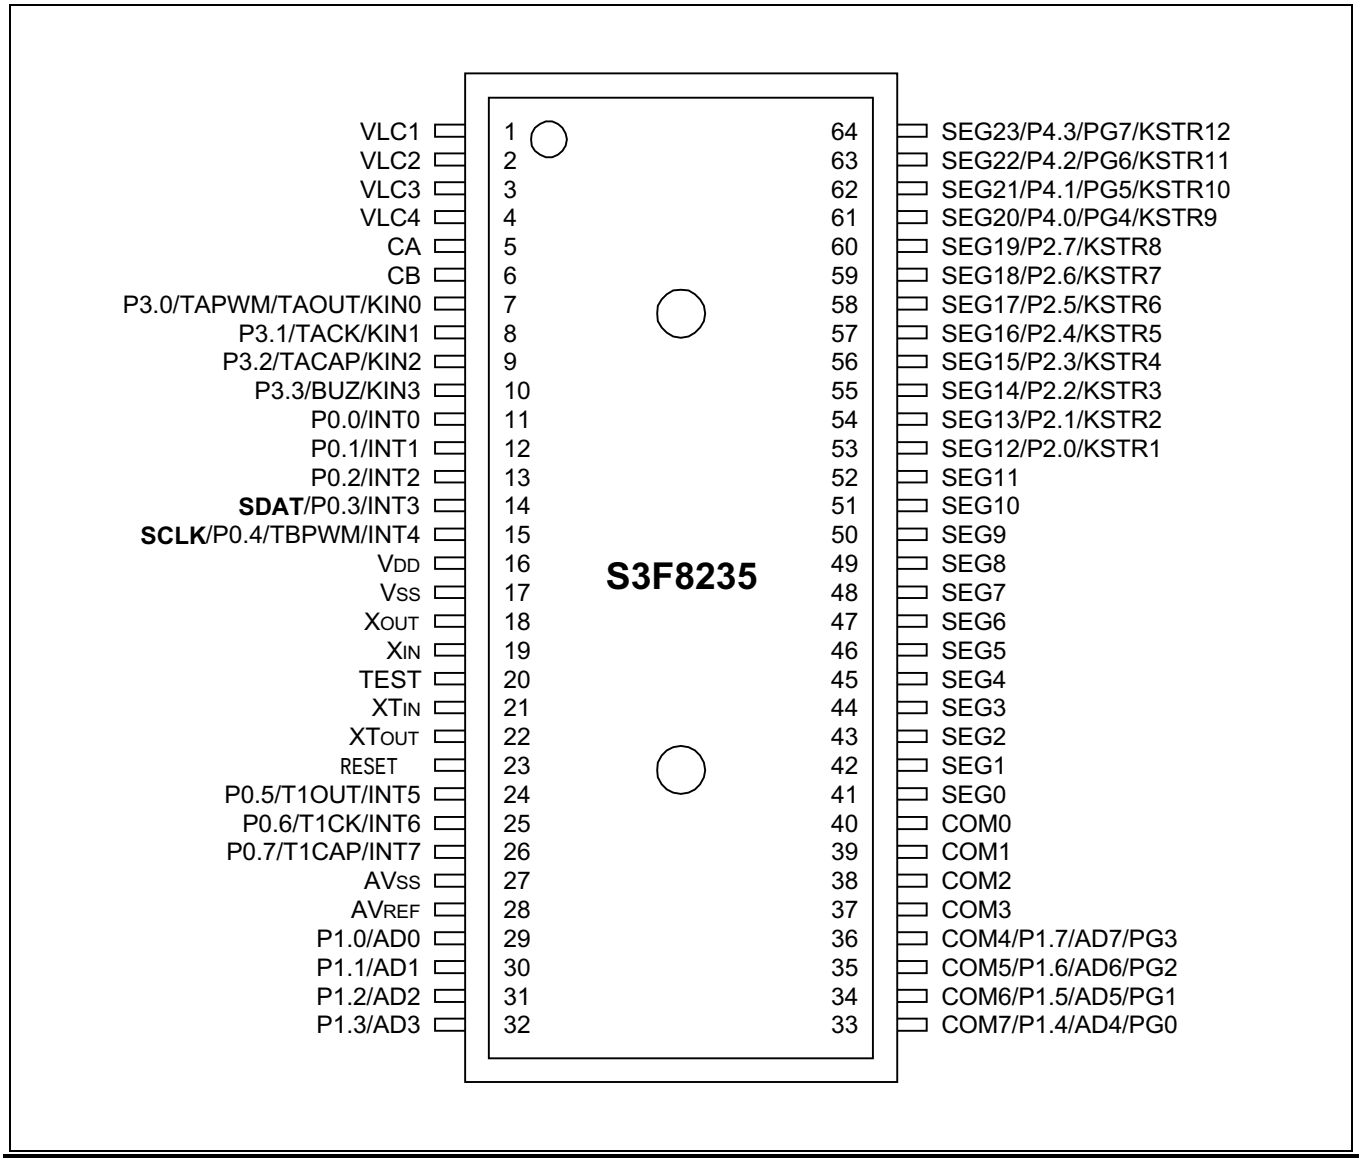

Figure 21-1. S3F8235 Pin Assignments (64-SDIP Package)

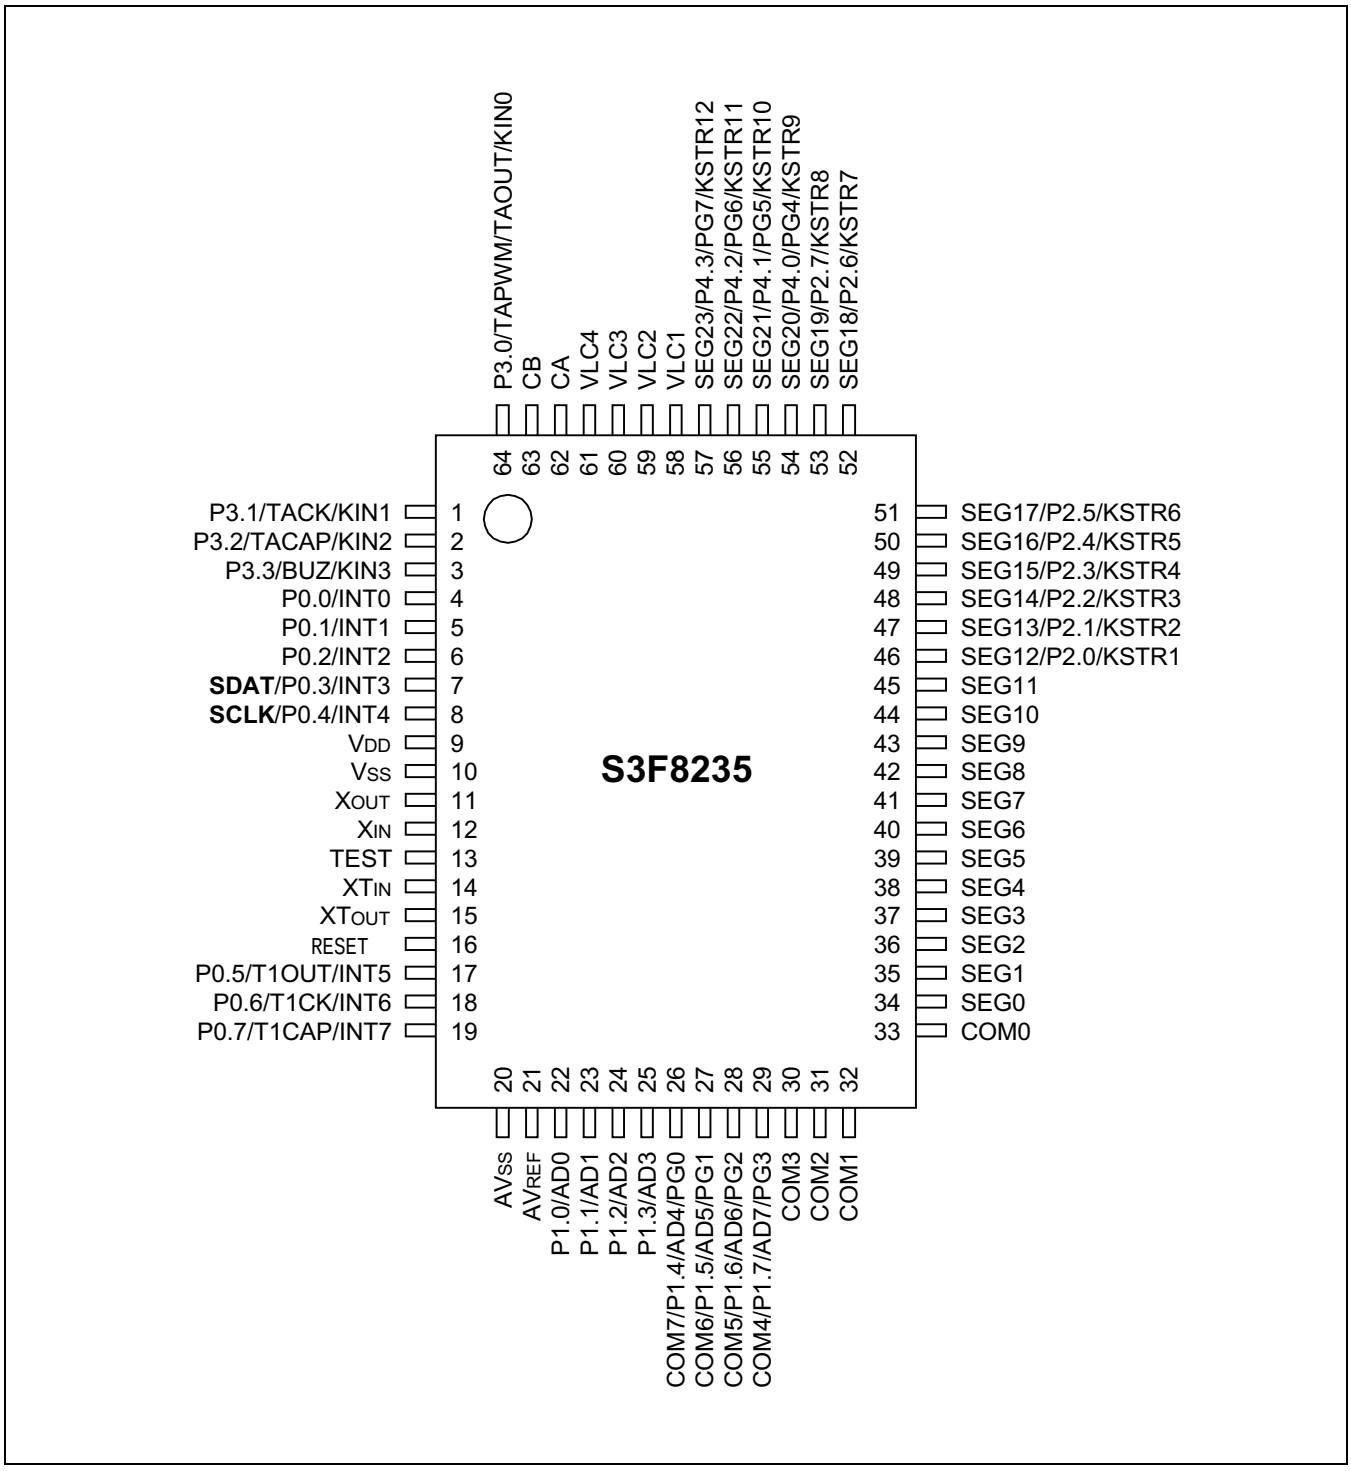

Figure 21-2. S3F8235 Pin Assignments (64-QFP Package)

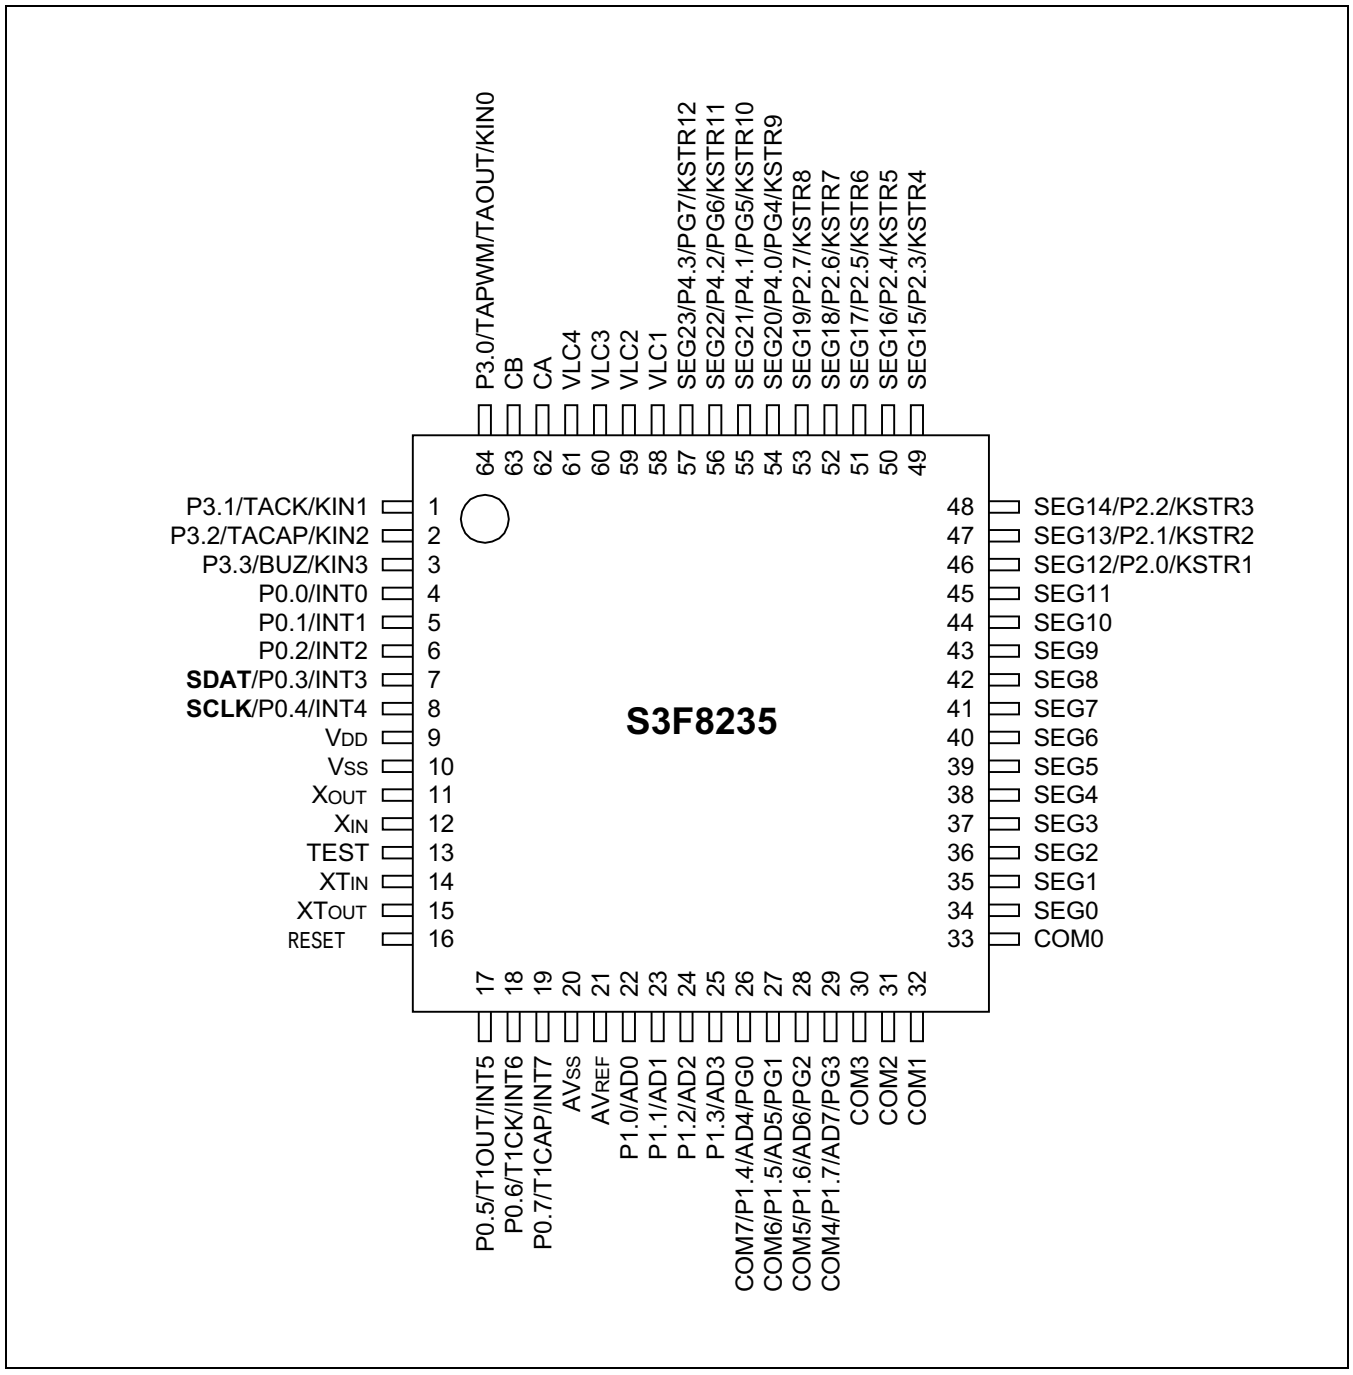

Figure 21-3. S3F8235 Pin Assignments (64-LQFP Package)

Table 21-1. Descriptions of Pins Used to Read/Write the EPROM

Main Chip	During Programming			
Pin Name	Pin Name	Pin No.	I/O	Function
P0.3	SDAT	14	I/O	Serial data pin. Output port when reading and input port when writing. Can be assigned as a Input/push-pull output port.
P0.4	SCLK	15	I/O	Serial clock pin. Input only pin.
V_{PP}	TEST	20	I	Power supply pin for FlashROM cell writing (indicates that FLASH MCU enters into the writing mode). When 12.5 V is applied, FLASH MCU is in writing mode and when 5 V is applied, FLASH MCU is in reading mode. (Option)
RESET	RESET	23	I	Chip Initialization
V_{DD}/V_{SS}	V_{DD}/V_{SS}	16/17	–	Logic power supply pin. V_{DD} should be tied to +5 V during programming.

Table 21-2. Comparison of S3F8235 and S3C8235 Features

Characteristic	S3F8235	S3C8235
Program Memory	16K-byte Flash ROM	16K-byte mask ROM
Operating Voltage (V_{DD})	2.0 V to 5.5 V	2.0 V to 5.5 V
FLASH MCU Programming Mode	V_{DD} = 5 V, V_{PP} (TEST) = 12.5 V	
Programmability	User Program multi time	Programmed at the factory

OPERATING MODE CHARACTERISTICS

When 12.5 V is supplied to the V_{PP} (TEST) pin of the S3F8235, the FlashROM programming mode is entered. The operating mode (read, write, or read protection) is selected according to the input signals to the pins listed in Table 21-3 below.

Table 21-3. Operating Mode Selection Criteria

V_{DD}	V_{PP}(TEST)	REG/MEM	Address (A15–A0)	R/W	Mode
5 V	5 V	0	0000H	1	Flash ROM read
	12.5 V	0	0000H	0	Flash ROM program
	12.5 V	0	0000H	1	Flash ROM verify
	12.5 V	1	0E3FH	0	Flash ROM read protection

NOTE: "0" means Low level; "1" means High level.

Table 21-4. D.C Electrical Characteristics

(T_A = -40 °C to +85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Operating voltage	V_{DD}	f_{CPU} = 8 MHz	2.7	–	5.5	V
		f_{CPU} = 4 MHz	2.0	–	5.5	
Input high voltage	V_{IH1}	All input pins except V_{IH2}	0.8 V_{DD}	–	V_{DD}	
	V_{IH2}	X_{IN}, XT_{IN}	V_{DD}-0.1	–		
Input low voltage	V_{IL1}	All input pins except V_{IL2}	–	–	0.2 V_{DD}	
	V_{IL2}	X_{IN}, XT_{IN}			0.1	

NOTE: P0 and P3 are schmitt trigger ports.

Table 21-4. D.C. Electrical Characteristics (Continued)

(T_A = -40 °C to +85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Output high voltage	V_{OH1}	V_{DD} = 2.4 V; I_{OH} = -4 mA Port 0.4 only	V_{DD} - 0.7	V_{DD} - 0.3	–	V
	V_{OH2}	V_{DD} = 5 V; I_{OH} = -4 mA Port 3	V_{DD} - 1.0	–	–	
	V_{OH3}	V_{DD} = 5 V; I_{OH} = -1 mA All output pins except P0.4,P3	V_{DD} - 1.0	–	–	
Output low voltage	V_{OL1}	V_{DD} = 2.4 V; I_{OL} = 12 mA P0.4 only		0.3	0.5	
	V_{OL2}	V_{DD} = 5 V; I_{OL} = 15 mA P3		0.4	2.0	
	V_{OL3}	V_{DD} = 5 V; I_{OL} = 4 mA All output pins except P0.4,P3	–	0.4	2.0	
Input high leakage current	I_{LIH1}	V_{IN} = V_{DD} All input pins except I_{LIH2}	–	–	3	µA
	I_{LIH2}	V_{IN} = V_{DD}, X_{IN}, XT_{IN}			20	
Input low leakage current	I_{LIL1}	V_{IN} = 0 V All input pins except I_{LIL2}	–	–	-3	
	I_{LIL2}	V_{IN} = 0 V, X_{IN}, XT_{IN}			-20	
Output high leakage current	I_{LOH}	V_{OUT} = V_{DD} All I/O pins and Output pins	–	–	3	
Output low leakage current	I_{LOL}	V_{OUT} = 0 V All I/O pins and Output pins	–	–	-3	
Oscillator feed back resistors	R_{OSC1}	V_{DD} = 5.0 V T_A = 25 °C X_{IN} = V_{DD}, X_{OUT} = 0 V	800	1000	1200	kΩ
Pull-up resistor	R_{L1}	V_{IN} = 0 V; V_{DD} = 5 V ±10 % Port 0,1,2,4 T_A = 25°C	25	50	100	
	R_{L2}	V_{IN} = 0 V; V_{DD} = 5 V ±10% T_A=25 °C, RESET only	110	210	310	
COM output voltage deviation	V_{DC}	V_{DD} = V_{LC3} = 4 V (V_{LC3}-COMi) IO = ± 15 p-µA (i = 0-3)	–	± 60	± 200	mV
SEG output voltage deviation	V_{DS}	V_{DD} = V_{LC3} = 4 V (V_{LC3}-SEGi) IO = ± 15 p-µA (i = 0-23)	–	± 60	± 200	

Table 21-4. D.C. Electrical Characteristics (Concluded)

(T_A = -40 °C to + 85 °C, V_{DD} = 2.0 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Supply current (1)	I_{DD1} (2)	V_{DD} = 5 V ± 10 % 8 MHz crystal oscillator	–	12	25	mA
		4 MHz crystal oscillator		4	10	
		V_{DD} = 3 V ± 10 % 8 MHz crystal oscillator		3	8	
		4 MHz crystal oscillator		1	5	
	I_{DD2}	Idle mode: V_{DD} = 5 V ± 10 % 8 MHz crystal oscillator		3	10	
		4 MHz crystal oscillator		1.5	4	
		Idle mode: V_{DD} = 3 V± 10 % 8 MHz crystal oscillator		1.2	3	
		4 MHz crystal oscillator		1.0	2.0	
	I_{DD3}	Sub operating: main-osc stop V_{DD} = 3 V ± 10 % 32768 Hz crystal oscillator		40	80	µA
	I_{DD4}	Sub idle mode: main osc stop V_{DD} = 3 V ± 10 % 32768 Hz crystal oscillator		7	14	
	I_{DD5}	Main stop mode : sub-osc stop V_{DD} = 5 V ± 10 %		1	3	
		V_{DD} = 3 V ± 10 %		0.5	2	

NOTES:

1. Supply current does not include current drawn through internal pull-up resistors or external output current loads.
2. I_{DD1} and I_{DD2} include a power consumption of subsystem oscillator.
3. I_{DD3} and I_{DD4} are the current when the main system clock oscillation stop and the subsystem clock is used.
   And they does not include the LCD and Voltage booster and voltage level detector current.
4. I_{DD5} is the current when the main and subsystem clock oscillation stop.
5. Voltage booster's operating voltage rage is 2.0V to 5.5V.
6. If you use LVR module, supply current increase refer to Table 19-12.

Table 21-5. LVR(Low Voltage Reset) Circuit Characteristics

Parameter	Symbol	Test Condition	Min	Typ	Max	Unit
LVR Voltage high	V_{LVRH}		2.4 2.8 4.0			V
LVR Voltage low	V_{LVRL}		2.0 2.4 3.2	2.2 2.6 3.6	2.4 2.8 4.0	V
Power supply voltage riseing time	T_R		10			µS
Power supply voltage off time	T_{OFF}		0.5			S
LVR circuit consumption current	I_{DDPR}	V_{DD} = 5V +/- 10%		65	100	µA
		V_{DD} = 3V		45	80	

NOTES:
1. 2^{16}/fx (= 6.55 ms at fx = 10 MHz)
2. Current consumed when Low Voltage reset circuit is provided internally.

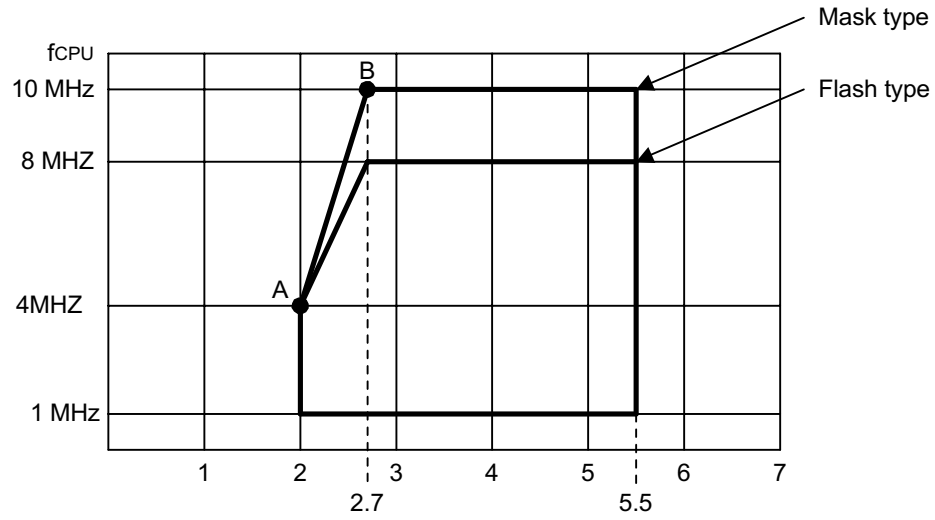

Figure 21-5. Operating Voltage Range

22 DEVELOPMENT TOOLS

OVERVIEW

Samsung provides a powerful and easy-to-use development support system in turnkey form. The development support system is configured with a host system, debugging tools, and support software. For the host system, any standard computer that operates with MS-DOS as its operating system can be used. One type of debugging tool including hardware and software is provided: the sophisticated and powerful in-circuit emulator, SMDS2+, for S3C7, S3C9, S3C8 families of microcontrollers. The SMDS2+ is a new and improved version of SMDS2. Samsung also offers support software that includes debugger, assembler, and a program for setting options.

SHINE

Samsung Host Interface for In-Circuit Emulator, SHINE, is a multi-window based debugger for SMDS2+. SHINE provides pull-down and pop-up menus, mouse support, function/hot keys, and context-sensitive hyper-linked help. It has an advanced, multiple-windowed user interface that emphasizes ease of use. Each window can be sized, moved, scrolled, highlighted, added, or removed completely.

SAMA ASSEMBLER

The Samsung Arrangeable Microcontroller (SAM) Assembler, SAMA, is a universal assembler, and generates object code in standard hexadecimal format. Assembled program code includes the object code that is used for ROM data and required SMDS program control data. To assemble programs, SAMA requires a source file and an auxiliary definition (DEF) file with device specific information.

SASM88

The SASM88 is a relocatable assembler for Samsung's S3C8-series microcontrollers. The SASM88 takes a source file containing assembly language statements and translates into a corresponding source code, object code and comments. The SASM88 supports macros and conditional assembly. It runs on the MS-DOS operating system. It produces the relocatable object code only, so the user should link object file. Object files can be linked with other object files and loaded into memory.

HEX2ROM

HEX2ROM file generates ROM code from HEX file which has been produced by assembler. ROM code must be needed to fabricate a microcontroller which has a mask ROM. When generating the ROM code (.OBJ file) by HEX2ROM, the value "FF" is filled into the unused ROM area up to the maximum ROM size of the target device automatically.

TARGET BOARDS

Target boards are available for all S3C8-series microcontrollers. All required target system cables and adapters are included with the device-specific target board.

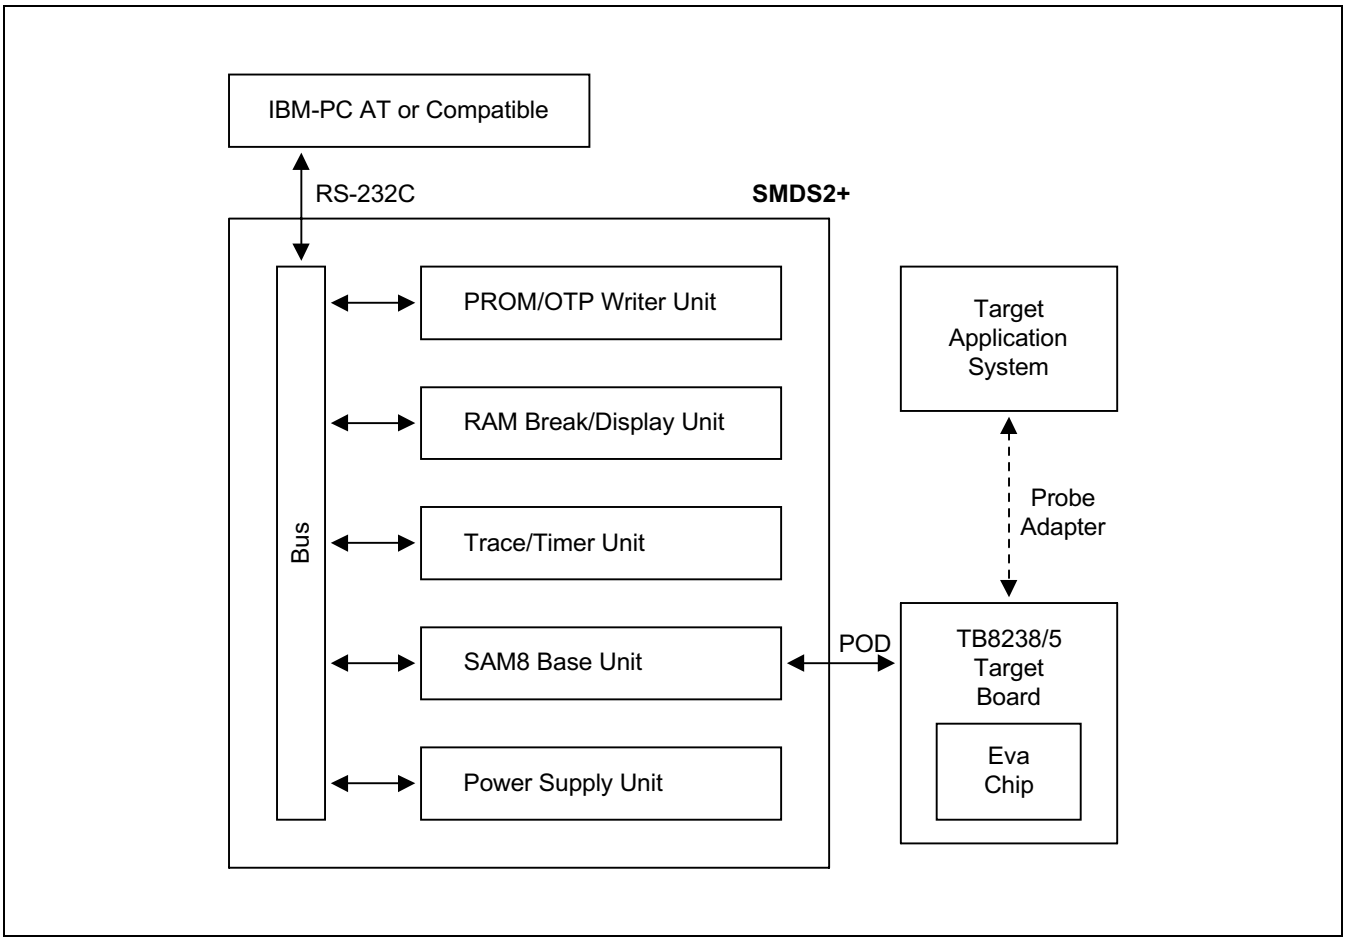

Figure 22-1. SMDS Product Configuration (SMDS2+)

TB8238/5 TARGET BOARD

The TB8238/5 target board is used for the S3C8238/C8325/F8235 microcontroller. It is supported with the SMDS2+, Smart Kit and OPENice.

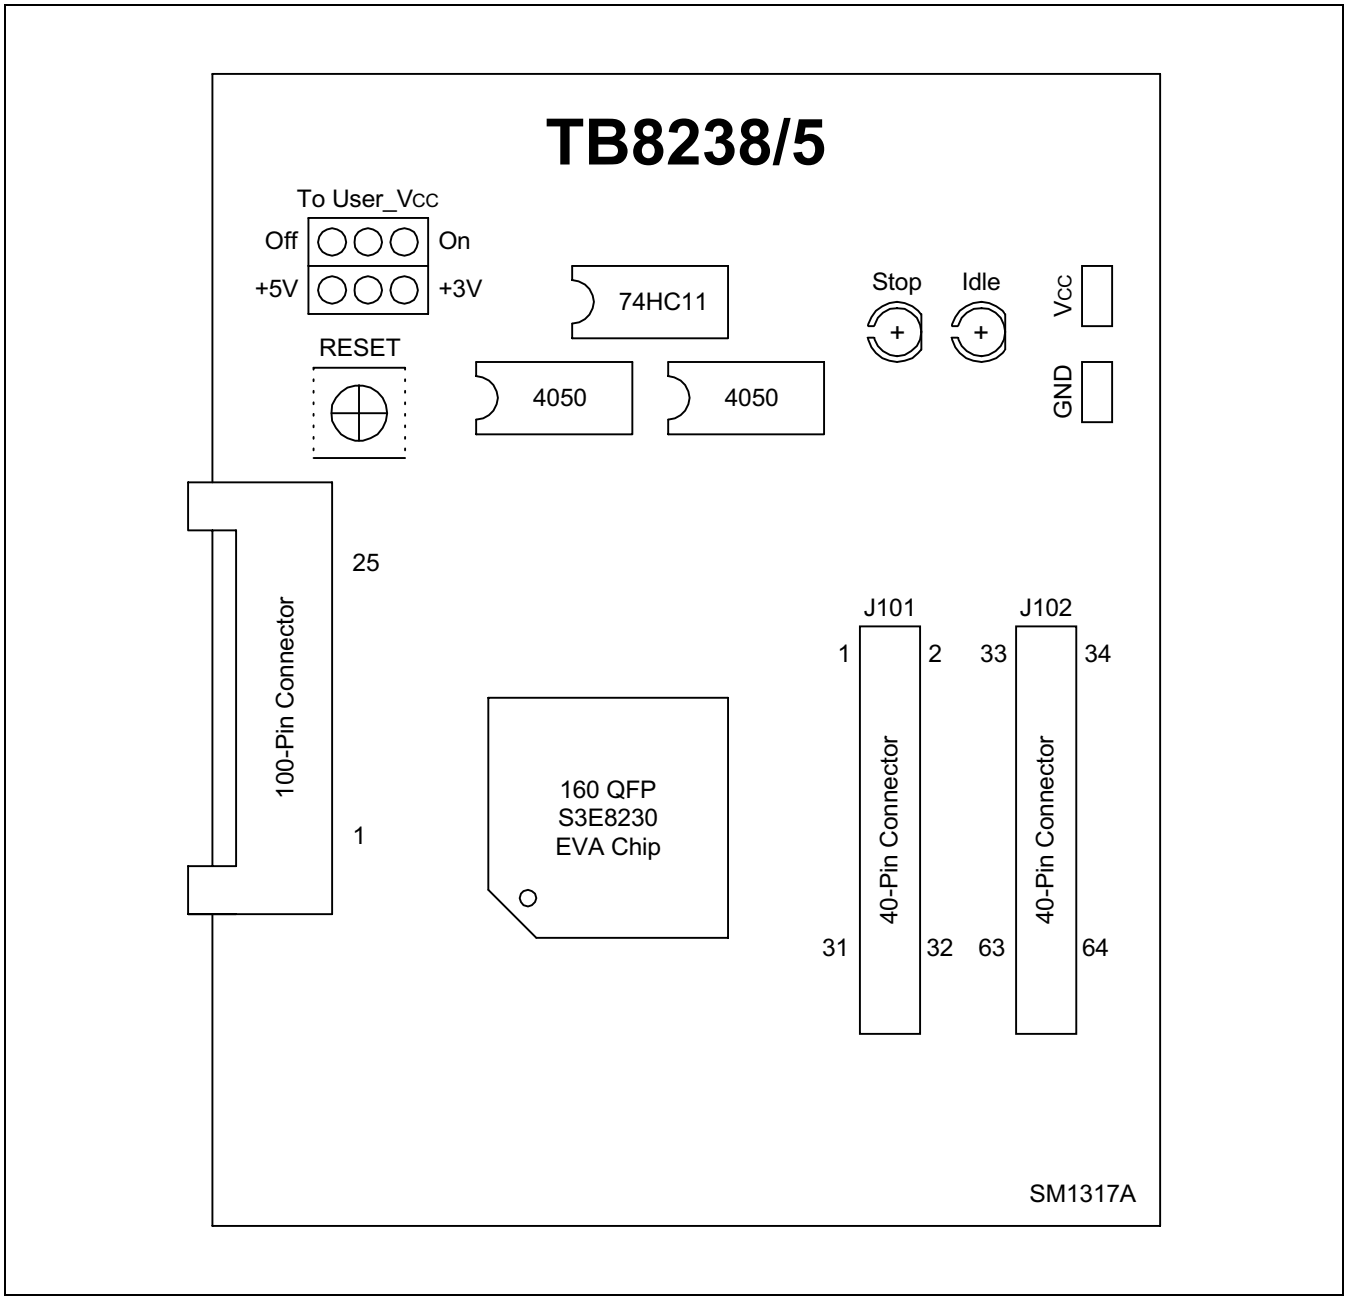

Figure 22-2. TB8238/5 Target Board Configuration

Table 22-1. Power Selection Settings for TB8238/5

"To User_Vcc" Settings	Operating Mode	Comments
To User_Vcc Off ○ ● ● On		The SMDS2/SMDS2+ supplies V_{CC} to the target board (evaluation chip) and the target system.
To User_Vcc Off ● ● ○ On		The SMDS2/SMDS2+ supplies V_{CC} only to the target board (evaluation chip). The target system must have its own power supply.

NOTE: The following symbol in the "To User_Vcc" Setting column indicates the electrical short (off) configuration:

Table 22-2. Power Selection Settings for EVA CHIP Operation (For using SMDS2+ only)

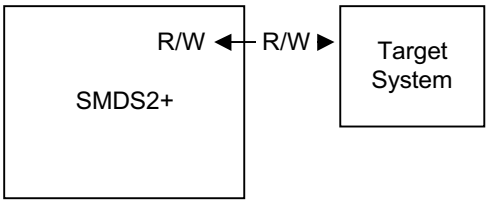
"To User_Vcc" ettings	Operating Mode	Comments
EVA-CHIP 3V ● ● 5V		The SMDS2+ supplies 5V to TB8238/5 target board (S3E8230). So, the target system be operated by 5V.
EVA-CHIP 3V ● ● 5V		The SMDS2+ supplies 3V to TB8238/5 target board (S3E8230). So, the target system be operated by 3V.

NOTE: For using SMDS2, Fix to 5V side 'EVA-CHIP' settings.

SMDS2+ SELECTION (SAM8)

In order to write data into program memory that is available in SMDS2+, the target board should be selected to be for SMDS2+ through a switch as follows. Otherwise, the program memory writing function is not available.

Table 22-3. The SMDS2+ Tool Selection Setting

"SW1" Setting	Operating Mode
	


IDLE LED

The Yellow LED is ON when the evaluation chip (S3E8230) is in idle mode.

STOP LED

The Red LED is ON when the evaluation chip (S3E8230) is in stop mode.
