Features

- Utilizes the ARM7TDMI[™] ARM Thumb Processor Core
 - High-performance 32-bit RISC Architecture
 - High-density 16-bit Instruction Set
 - Leader in MIPS/Watt
 - Embedded ICE (In-Circuit Emulation)
- 8K Bytes Internal SRAM
- Fully-programmable External Bus Interface (EBI)
 - Maximum External Address Space of 128M Bytes
 - 8 Chip Selects
 - Software Programmable 8/16-bit External Databus
- 8-level Priority, Individually Maskable, Vectored Interrupt Controller
- 7 External Interrupts, Including a High-priority, Low-latency Interrupt Request
- 58 Programmable I/O Lines
- 6-channel 16-bit Timer/Counter
- 6 External Clock Inputs and 2 Multi-purpose I/O Pins per Channel
- 3 USARTs
- Master/Slave SPI Interface
 - 8-bit to 16-bit Programmable Data Length
 - 4 External Slave Chip Selects
- Programmable Watchdog Timer
- 8-channel 10-bit ADC
- 2-channel 10-bit DAC
- Clock Generator with On-chip Main Oscillator and PLL for Multiplication

 3 to 20 MHz Frequency Range Main Oscillator
- Real-time Clock with On-chip 32 kHz Oscillator
- Battery Backup Operation and External Alarm
- 8-channel Peripheral Data Controller for USARTs and SPIs
- Advanced Power Management Controller (APMC)
 - Normal, Wait, Slow, Standby and Power-down modes
- IEEE 1149.1 JTAG Boundary-scan on all Digital Pins
- Fully Static Operation: 0 Hz to 33 MHz Internal Frequency Range at VDDCORE = 3.0V, 85°C
- 2.7V to 3.6V Core Operating Range, 2.7V to 5.5V I/O Operating Range
- 2.7V to 3.6V Analog Operating Range
- 1.8V to 3.6V Backup Battery Operating Range
- 2.7V to 3.6V Oscillator and PLL Operating Range
- -40°C to +85°C Temperature Range
- Available in a 176-lead TQFP or 176-ball BGA Package

Description

The AT91M55800A is a member of the Atmel AT91 16/32-bit microcontroller family, which is based on the ARM7TDMI processor core. This processor has a high-performance 32-bit RISC architecture with a high-density 16-bit instruction set and very low power consumption. In addition, a large number of internally banked registers result in very fast exception handling, making the device ideal for real-time control applications.

The fully programmable External Bus Interface provides a direct connection to off-chip memory in as fast as one clock cycle for a read or write operation. An eight-level priority vectored interrupt controller in conjunction with the peripheral data controller significantly improve the real-time performance of the device.

The device is manufactured using Atmel's high-density CMOS technology. By combining the ARM7TDMI processor core with an on-chip SRAM, a wide range of peripheral functions, analog interfaces and low-power oscillators on a monolithic chip, the Atmel AT91M55800A is a powerful microcontroller that provides a highly-flexible and costeffective solution to many ultra low-power applications.

AT91 ARM[®] Thumb[®] Microcontrollers

AT91M55800A Summary

Rev. 1745BS-ATARM-02/02

Note: This is a summary document. A complete document is available on our web site at www.atmel.com.

AT91M55800A

Architectural Overview	The AT91M55800A microcontroller integrates an ARM7TDMI with its embedded ICE inter- face, memories and peripherals. Its architecture consists of two main buses, the Advanced System Bus (ASB) and the Advanced Peripheral Bus (APB). Designed for maximum perfor- mance and controlled by the memory controller, the ASB interfaces the ARM7TDMI processor with the on-chip 32-bit memories, the External Bus Interface (EBI) and the AMBA [™] Bridge. The AMBA Bridge drives the APB, which is designed for accesses to on-chip peripherals and optimized for low power consumption.
	The AT91M55800A microcontroller implements the ICE port of the ARM7TDMI processor on dedicated pins, offering a complete, low cost and easy-to-use debug solution for target debugging.
Memory	The AT91M55800A microcontroller embeds 8K bytes of internal SRAM. The internal memory is directly connected to the 32-bit data bus and is single-cycle accessible.
	The AT91M55800A microcontroller features an External Bus Interface (EBI), which enables connection of external memories and application-specific peripherals. The EBI supports 8- or 16-bit devices and can use two 8-bit devices to emulate a single 16-bit device. The EBI implements the early read protocol, enabling faster memory accesses than standard memory interfaces.
Peripherals	The AT91M55800A microcontroller integrates several peripherals, which are classified as sys- tem or user peripherals. All on-chip peripherals are 32-bit accessible by the AMBA Bridge, and can be programmed with a minimum number of instructions. The peripheral register set is composed of control, mode, data, status and enable/disable/status registers.
	An on-chip, 10-channel Peripheral Data Controller (PDC) transfers data between the on-chip USARTs/SPI and the on and off-chip memories without processor intervention. One PDC channel is connected to the receiving channel and one to the transmitting channel of each USART and of the SPI.
	Most importantly, the PDC removes the processor interrupt handling overhead and signifi- cantly reduces the number of clock cycles required for a data transfer. It can transfer up to 64K contiguous bytes. As a result, the performance of the microcontroller is increased and the power consumption reduced.
System Peripherals	The External Bus Interface (EBI) controls the external memory and peripheral devices via an 8- or 16-bit data bus and is programmed through the APB. Each chip select line has its own programming register.
	The Advanced Power Management Controller (APMC) optimizes power consumption of the product by controlling the clocking elements such as the oscillators and the PLL, system and user peripheral clocks, and the power supplies.
	The Advanced Interrupt Controller (AIC) controls the internal interrupt sources from the inter- nal peripherals and the eight external interrupt lines (including the FIQ), to provide an interrupt and/or fast interrupt request to the ARM7TDMI. It integrates an 8-level priority controller and, using the auto-vectoring feature, reduces the interrupt latency time.
	The Real-time Clock (RTC) peripheral is designed for very low power consumption, and com- bines a complete time-of-day clock with alarm and a two-hundred year Gregorian calendar, complemented by a programmable periodic interrupt.
	The Parallel Input/Output Controllers (PIOA and PIOB) control the 58 I/O lines. They enable the user to select specific pins for on-chip peripheral input/output functions, and general-purpose input/output signal pins. The PIO controllers can be programmed to detect an interrupt on a signal change from each line.

The Watchdog (WD) can be used to prevent system lock-up if the software becomes trapped in a deadlock.

The Special Function (SF) module integrates the Chip ID and Reset Status registers.

User Peripherals Three USARTs, independently configurable, enable communication at a high baud rate in synchronous or asynchronous mode. The format includes start, stop and parity bits and up to 8 data bits. Each USART also features a Timeout and a Time Guard Register, facilitating the use of the two dedicated Peripheral Data Controller (PDC) channels.

The six 16-bit Timer/Counters (TC) are highly programmable and support capture or waveform modes. Each TC channel can be programmed to measure or generate different kinds of waves, and can detect and control two input/output signals. Each TC also has three external clock signals.

The SPI provides communication with external devices in master or slave mode. It has four external chip selects which can be connected to up to 15 devices. The data length is programmable, from 8- to 16-bit.

The two identical 4-channel 10-bit analog-to-digital converters (ADC) are based on a Successive Approximation Register (SAR) approach.

The two identical single-channel 10-bit digital-to-analog converters (DAC) each have a dedicated PDC channel.

Product Overview

Power Supplies

The AT91M55800A has 5 kinds of power supply pins:

- VDDCORE pins, which power the chip core
- VDDIO pins, which power the I/O Lines
- VDDPLL pins, which power the oscillator and PLL cells
- VDDA pins, which power the analog peripherals ADC and DAC
- VDDBU pins, which power the RTC, the 32768 Hz oscillator and the Shut-down Logic of the APMC

VDDIO and VDDCORE are separated to permit the I/O lines to be powered with 5V, thus resulting in full TTL compliance.

The following ground pins are provided:

- GND for both VDDCORE and VDDIO
- GNDPLL for VDDPLL
- GNDA for VDDA
- GNDBU for VDDBU

All of these ground pins must be connected to the same voltage (generally the board electric ground) with wires as short as possible. GNDPLL, GNDA and GNDBU are provided separately in order to allow the user to add a decoupling capacitor directly between the power and ground pads. In the same way, the PLL filter resistor and capacitors must be connected to the device and to GNDBU with wires as short as possible. Also, the external load capacitances of the main oscillator crystal and the 32768 Hz crystal must be connected respectively to GNDPLL and to GNDBU with wires as short as possible.

The main constraints applying to the different voltages of the device are:

- VDDBU must be lower than or equal to VDDCORE
- VDDA must be higher than or equal to VDDCORE
- VDDCORE must be lower than or equal to VDDIO

The nominal power combinations supported by the AT91M55800A are described in the following table:

Table 5. Nominal Power Combinations

VDDIO	VDDCORE	DDCORE VDDA		VDDBU	Maximum Operating Frequency
3V	3V	3V	3V	3V	33 MHz
3.3V	3.3V	3.3V	3.3V	3.3V	33 MHz
5V	3.3V	3.3V	3.3V	3.3V	33 MHz

Input/Output Considerations

After the reset, the peripheral I/Os are initialized as inputs to provide the user with maximum flexibility. It is recommended that in any application phase, the inputs to the AT91M55800A microcontroller be held at valid logic levels to minimize the power consumption.

Master Clock	Master Clock is generated in one of the following ways, depending on programming in the APMC registers:
	From the 32768 Hz low-power oscillator that clocks the RTC
	• The on-chip main oscillator, together with a PLL, generate a software-programmable main clock in the 500 Hz to 33 MHz range. The main oscillator can be bypassed to allow the user to enter an external clock signal.
	The Master Clock (MCK) is also provided as an output of the device on the MCKO pin, whose state is controlled by the APMC module.
Reset	Reset restores the default states of the user interface registers (defined in the user interface of each peripheral), and forces the ARM7TDMI to perform the next instruction fetch from address zero. Aside from the program counter, the ARM7TDMI registers do not have defined reset states.
NRST Pin	NRST is active low-level input. It is asserted asynchronously, but exit from reset is synchro- nized internally to the MCK. At reset, the source of MCK is the Slow Clock (32768 Hz crystal), and the signal presented on MCK must be active within the specification for a minimum of 10 clock cycles up to the rising edge of NRST, to ensure correct operation.
Watchdog Reset	The watchdog can be programmed to generate an internal reset. In this case, the reset has the same effect as the NRST pin assertion, but the BMS and NTRI pins are not sampled. Boot Mode and Tri-state Mode are not updated. If the NRST pin is asserted and the watchdog triggers the internal reset, the NRST pin has priority.
Emulation Functions	
Tri-state Mode	The AT91M55800A provides a Tri-state Mode, which is used for debug purposes. This enables the connection of an emulator probe to an application board without having to desolder the device from the target board. In Tri-state Mode, all the output pin drivers of the AT91M55800A microcontroller are disabled.
	To enter Tri-state Mode, the NTRI pin must be held low during the last 10 clock cycles before the rising edge of NRST. For normal operation the NTRI pin must be held high during reset, by a resistor of up to 400K Ohm.
	NTRI is multiplexed with I/O line PA18 and USART 1 serial data transmit line TXD1.
	Standard RS232 drivers generally contain internal 400K Ohm pull-up resistors. If TXD1 is con- nected to a device not including this pull-up, the user must make sure that a high level is tied on NTRI while NRST is asserted.
JTAG/ICE Debug Mode	ARM Standard Embedded In-Circuit Emulation is supported via the JTAG/ICE port. It is con- nected to a host computer via an external ICE Interface. The JTAG/ICE debug mode is enabled when JTAGSEL is low.
	In ICE Debug Mode the ARM Core responds with a non-JTAG chip ID which identifies the core to the ICE system. This is not JTAG compliant.

IEEE 1149.1 JTAG Boundary- scan	JTAG Boundary-scan is enabled when JTAGSEL is high. The functions SAMPLE, EXTEST and BYPASS are implemented. There is no JTAG chip ID. The Special Func- tion module provides a chip ID which is independent of JTAG.
	It is not possible to switch directly between JTAG and ICE operations. A chip reset must be performed (NRST and NTRST) after JTAGSEL is changed.
Memory Controller	The ARM7TDMI processor address space is 4G bytes. The memory controller decodes the internal 32-bit address bus and defines three address spaces:
	 Internal memories in the four lowest megabytes
	 Middle space reserved for the external devices (memory or peripherals) controlled by the EBI
	 Internal peripherals in the four highest megabytes
	In any of these address spaces, the ARM7TDMI operates in Little-Endian mode only.
Internal Memories	The AT91M55800A microcontroller integrates an 8-Kbyte primary SRAM bank. This memory bank is mapped at address 0x0 (after the remap command), allowing ARM7TDMI exception vectors between 0x0 and 0x20 to be modified by the software. The rest of the bank can be used for stack allocation (to speed up context saving and restoring), or as data and program storage for critical algorithms. All internal memory is 32 bits wide and single-clock cycle accessible. Byte (8-bit), half-word (16-bit) or word (32-bit) accesses are supported and are executed within one cycle. Fetching Thumb or ARM instructions is supported and internal memory can store twice as many Thumb instructions as ARM ones.
Boot Mode Select	The ARM reset vector is at address 0x0. After the NRST line is released, the ARM7TDMI executes the instruction stored at this address. This means that this address must be mapped in nonvolatile memory after the reset.
	The input level on the BMS pin during the last 10 clock cycles before the rising edge of the NRST selects the type of boot memory (see Table 5).

The BMS pin is multiplexed with the I/O line PB18 that can be programmed after reset like any standard PIO line.

Table 6. Boot Mode Select

BMS	Boot Mode
1	External 8-bit memory on NCS0
0	External 16-bit memory on NCS0

Remap Command The ARM vectors (Reset, Abort, Data Abort, Prefetch Abort, Undefined Instruction, Interrupt, Fast Interrupt) are mapped from address 0x0 to address 0x20. In order to allow these vectors to be redefined dynamically by the software, the AT91M55800A microcontroller uses a remap command that enables switching between the boot memory and the internal RAM bank addresses. The remap command is accessible through the EBI User Interface, by writing one in RCB of EBI_RCR (Remap Control Register). Performing a remap command is mandatory if access to the other external devices (connected to chip selects 1 to 7) is required. The remap operation can only be changed back by an internal reset or an NRST assertion.

Abort Control

The abort signal providing a Data Abort or a Prefetch Abort exception to the ARM7TDMI is asserted when accessing an undefined address in the EBI address space.

No abort is generated when reading the internal memory or by accessing the internal peripherals, whether the address is defined or not.

External Bus Interface The External Bus Interface handles the accesses between addresses 0x0040 0000 and 0xFFC0 0000. It generates the signals that control access to the external devices, and can configure up to eight 16-Mbyte banks. In all cases it supports byte, half-word and word aligned accesses.

For each of these banks, the user can program:

- Number of wait states
- Number of data float times (wait time after the access is finished to prevent any bus contention in case the device is too long in releasing the bus)
- Data bus width (8-bit or 16-bit)
- With a 16-bit wide data bus, the user can program the EBI to control one 16-bit device (Byte Access Select Mode) or two 8-bit devices in parallel that emulate a 16-bit memory (Byte-write Access mode).

The External Bus Interface features also the Early Read Protocol, configurable for all the devices, that significantly reduces access time requirements on an external device.

Peripherals	The AT91M55800A peripherals are connected to the 32-bit wide Advanced Peripheral Bus. Peripheral registers are only word accessible. Byte and half-word accesses are not supported. If a byte or a half-word access is attempted, the memory controller automatically masks the lowest address bits and generates a word access.
	Each peripheral has a 16-Kbyte address space allocated (the AIC only has a 4-Kbyte address space).
Peripheral Registers	 The following registers are common to all peripherals: Control Register – write only register that triggers a command when a one is written to the corresponding position at the appropriate address. Writing a zero has no effect. Mode Register – read/write register that defines the configuration of the peripheral. Usually has a value of 0x0 after a reset. Data Registers – read and/or write register that enables the exchange of data between the processor and the peripheral. Status Register – read only register that returns the status of the peripheral. Enable/Disable/Status Registers – shadow command registers. Writing a one in the Enable Register resets the corresponding bit in the Status Register. Writing a bit to zero has no effect. This register access method maximizes the efficiency of bit manipulation, and enables modification of a register with a single non-interruptible instruction, replacing the costly read-modify-write operation. Unused bits in the peripheral registers are shown as "–" and must be written at 0 for upward compatibility. These bits read 0.
Peripheral Interrupt Control	The Interrupt Control of each peripheral is controlled from the status register using the interrupt mask. The status register bits are ANDed to their corresponding interrupt mask bits and the result is then ORed to generate the Interrupt Source signal to the Advanced Interrupt Controller.
	The interrupt mask is read in the Interrupt Mask Register and is modified with the Inter- rupt Enable Register and the Interrupt Disable Register. The enable/disable/status (or mask) makes it possible to enable or disable peripheral interrupt sources with a non- interruptible single instruction. This eliminates the need for interrupt masking at the AIC or Core level in real-time and multi-tasking systems.
Peripheral Data Controller	An on-chip, 10-channel Peripheral Data Controller (PDC) transfers data between the on- chip USARTs/SPI/DACs and the on and off-chip memories without processor interven- tion. One PDC channel is connected to the receiving channel and one to the transmitting channel of each USART and SPI. A single PDC channel is connected to each DAC.
	The user interface of a PDC channel is integrated in the memory space of each peripheral. It contains a 32-bit address pointer register and a 16-bit count register. When the programmed data is transferred, an end of transfer interrupt is generated by the corresponding peripheral.
	Most importantly, the PDC removes the processor interrupt handling overhead and sig- nificantly reduces the number of clock cycles required for a data transfer. It can transfer up to 64K contiguous bytes. As a result, the performance of the microcontroller is increased and the power consumption reduced.

AIMEL

System Peripherals

APMC: Advanced Power Management Controller	 The AT91M55800A Advanced Power Management Controller allows optimization of power consumption. The APMC enables/disables the clock inputs of most of the peripherals and the ARM core. Moreover, the main oscillator, the PLL and the analog peripherals can be put in standby mode allowing minimum power consumption to be obtained. The APMC provides the following operating modes: Normal mode: clock generator provides clock to the entire chip except the RTC. Wait mode: ARM core clock deactivated Slow Clock mode: clock generator deactivated, master clock 32 kHz Standby mode: RTC active, all other clocks disabled Power-down mode: RTC active, supply on the rest of the circuit deactivated
RTC: Real Time Clock	The AT91M55800A features a Real-time Clock (RTC) peripheral that is designed for very low power consumption. It combines a complete time-of-day clock with alarm and a two-hundred year Gregorian calendar, complemented by a programmable periodic interrupt. The time and calendar values are coded in Binary-Coded Decimal (BCD) format. The time format can be 24-hour mode or 12-hour mode with an AM/PM indicator.
	Updating time and calendar fields and configuring the alarm fields is performed by a parallel capture on the 32-bit data bus. An entry control is performed to avoid loading registers with incompatible BCD format data or with an incompatible date according to the current month/ year/century.
AIC: Advanced Interrupt Controller	 The AIC has an 8-level priority, individually maskable, vectored interrupt controller, and drives the NIRQ and NFIQ pins of the ARM7TDMI from: The external fast interrupt line (FIQ) The six external interrupt request lines (IRQ0 - IRQ6) The interrupt signals from the on-chip peripherals The AIC is largely programmable offering maximum flexibility, and its vectoring features reduce the real-time overhead in handling interrupts. The AIC also features a spurious vector, which reduces spurious interrupt handling to a minimum, and a protect mode that facilitates the debug capabilities.
PIO: Parallel I/O Controller	The AT91M55800A has 58 programmable I/O lines. 13 pins are dedicated as general-purpose I/O pins. The other I/O lines are multiplexed with an external signal of a peripheral to optimize the use of available package pins. The PIO lines are controlled by two separate and identical PIO Controllers called PIOA and PIOB. The PIO controller enables the generation of an interrupt on input change and insertion of a simple input glitch filter on any of the PIO pins.
WD: Watchdog	The Watchdog is built around a 16-bit counter, and is used to prevent system lock-up if the software becomes trapped in a deadlock. It can generate an internal reset or interrupt, or assert an active level on the dedicated pin NWDOVF. All programming registers are password-protected to prevent unintentional programming.
SF: Special Function	The AT91M55800A provides registers which implement the following special functions.Chip identificationRESET status

User Peripherals

USART: Universal Synchronous/	The AT91M55800A provides three identical, full-duplex, universal synchronous/asyn- chronous receiver/transmitters.					
Asynchronous Receiver Transmitter	Each USART has its own baud rate generator, and two dedicated Peripheral Data Con- troller channels. The data format includes a start bit, up to 8 data bits, an optional programmable parity bit and up to 2 stop bits.					
	The USART also features a Receiver Timeout register, facilitating variable-length frame support when it is working with the PDC, and a Time-guard register, used when interfac- ing with slow remote equipment.					
TC: Timer/Counter	The AT91M55800A features two Timer/Counter blocks that include three identical 16-bit timer/counter channels. Each channel can be independently programmed to perform a wide range of functions including frequency measurement, event counting, interval measurement, pulse generation, delay timing and pulse-width modulation.					
	The Timer/Counters can be used in Capture or Waveform mode, and all three counter channels can be started simultaneously and chained together.					
SPI: Serial Peripheral Interface	The SPI provides communication with external devices in master or slave mode. It has four external chip selects that can be connected to up to 15 devices. The data length is programmable, from 8- to 16-bit.					
ADC: Analog-to-digital Converter	The two identical 4-channel 10-bit analog-to-digital converters (ADC) are based on a Successive Approximation Register (SAR) approach.					
	Each ADC has 4 analog input pins, AD0 to AD3 and AD4 to AD7, digital trigger input AD0TRIG and AD1TRIG pins, and provides an interrupt signal to the AIC. Both ADCs share the analog power supply VDDA and GNDA pins, and the input reference voltage ADVREF pin.					
	Each channel can be enabled or disabled independently, and has its own data register. The ADC can be configured to automatically enter Sleep Mode after a conversion sequence, and can be triggered by the software, the Timer/Counter, or an external signal.					
DAC: Digital-to-analog Converter	Two identical 1-channel 10-bit digital-to-analog converters (DAC) each with a dedicated PDC channel.					
	Each DAC has an analog output pin, DA0 and DA1, and provides an interrupt signal to the AIC DA0IRQ and DA1IRQ. Both DACs share the analog power supply VDDA and GNDA pins, and the input reference DAVREF.

Soldering **Profile**

Table 12 gives the recommended soldering profile from J-STD-20.

Table 12. Soldering Profile

	Convection or IR/Convection	VPR
Average Ramp-up Rate (183°C to Peak)	3°C/sec. max.	10°C/sec.
Preheat Temperature 125°C ±25°C	120 sec. max	
Temperature Maintained Above 183°C	60 sec. to 150 sec.	
Time within 5°C of Actual Peak Temperature	10 sec. to 20 sec.	60 sec.
Peak Temperature Range	220 +5/-0°C or 235 +5/-0°C	215 to 219°C or 235 +5/-0°C
Ramp-down Rate	6°C/sec.	10°C/sec.
Time 25°C to Peak Temperature	6 min. max	

Small packages may be subject to higher temperatures if they are reflowed in boards with larger components. In this case, small packages may have to withstand temperatures of up to 235°C, not 220°C (IR reflow).

Recommended package reflow conditions depend on package thickness and volume. See Table 13.

Table 13. Recommended Package Reflow Conditions (TQFP and PBGA) ^(1, 2, 3)		
	Parameter	Temperature
	Convection	220 +5/-0°C

Parameter	Temperature
Convection	220 +5/-0°C
VPR	215 to 219°C
IR/Convection	220 +5/-0°C

Notes: 1. The packages are qualified by Atmel by using IR reflow conditions, not convection or VPR.

- 2. By default, the package level 1 is qualified at 220°C (unless 235°C is stipulated).
- 3. The body temperature is the most important parameter but other profile parameters such as total exposure time to hot temperature or heating rate may also influence component reliability.

A maximum of three reflow passes is allowed per component.
