Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

1 FEATURES

- Full static 80C51 CPU
- 8-bit CPU, ROM, RAM, I/O in a 40-lead DIP or 44-lead QFP package
- 16 kbytes ROM, expandable externally to 64 kbytes
- 256 bytes RAM, expandable externally to 64 kbytes
- Four 8-bit ports, 32 I/O lines
- Three 16-bit timer/event counters
- External memory expandable up to 128 kbytes: RAM up to 64 kbytes and ROM up to 64 kbytes
- On-chip oscillator suitable for RC, LC, quartz crystal or ceramic resonator
- Fifteen source, fifteen vector interrupt structure with two priority levels
- Full duplex serial port (UART)
- I²C-bus interface for serial transfer on two lines
- Enhanced architecture with:
 - non-page oriented instructions
 - direct addressing
 - four 8 byte RAM register banks
 - stack depth limited only by available internal RAM (maximum 256 bytes)
 - multiply, divide, subtract and compare instructions
- Reduced power consumption through Power-down and Idle modes
- Wake-up via external interrupts at Port 1
- Single supply voltage of 1.8 to 6.0 V
- Operating ambient temperature:
 - 83CL781: –40 to +85 °C
 - 83CL782: –25 to +55 °C.
- Frequency range of DC to 12 MHz
- Very low current consumption.

2 GENERAL DESCRIPTION

The term P83CL78x is used throughout this data sheet to refer to both the P83CL781 and P83CL782; differences between the devices are highlighted in the text.

The P83CL78x is manufactured in an advanced CMOS technology. The P83CL78x has the same instruction set as the 80C51, consisting of over 100 instructions: 49 one-byte, 46 two-byte, and 16 three-byte. The device has low power consumption and a wide range of supply voltage; there are two software-selectable modes of reduced activity for further power reduction: Idle and Power-down. For emulation purposes, the P85CL781 (piggy-back version) with 256 bytes of RAM is recommended.

The P83CL782 is a faster version of the P83CL781 and operates at a maximum frequency of 12 MHz at $V_{DD} \geq 3.1$ V.

This data sheet details the specific properties of the P83CL78x. For details of the 80C51 core and the I²C-bus see "Data Handbook IC20".

3 APPLICATIONS

The P83CL78x is an 8-bit general purpose microcontroller especially suited for cordless telephone applications. The P83CL78x also functions as an arithmetic processor having facilities for both binary and BCD arithmetic plus bit-handling capabilities.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

8 FUNCTIONAL DESCRIPTION OVERVIEW

This chapter gives a brief overview of the device. The detailed functional description is in the following chapters:

Chapter 9 "Memory organization"

Chapter 10 "I/O facilities"

Chapter 11 "Timer/event counters"

Chapter 12 "Reduced power modes"

Chapter 13 "I²C-bus serial I/O"

Chapter 14 "Standard serial interface SIO0: UART"

Chapter 15 "Interrupt system"

Chapter 16 "Oscillator circuitry"

Chapter 17 "Reset".

8.1 General

The P83CL78x is a stand-alone high-performance CMOS microcontroller designed for use in real-time applications such as instrumentation, industrial control, intelligent computer peripherals and consumer products. The device provides hardware features, architectural enhancements and new instructions to function as a controller for applications requiring up to 64 kbytes of Program Memory and/or up to 64 kbytes of data storage.

The P83CL78x contains a non-volatile 16 kbyte read-only Program Memory; a static 256 byte read/write Data Memory; 32 I/O lines; three 16-bit timer/event counters; a fifteen-source, two priority-level, nested interrupt structure and on-chip oscillator and timing circuit.

The device has two software-selectable modes of reduced activity for power reduction:

- **Idle mode**; freezes the CPU while allowing the timers, serial I/O and interrupt system to continue functioning.
- **Power-down mode**; saves the RAM contents but freezes the oscillator causing all other chip functions to be inoperative.

In addition, two serial interfaces are provided on-chip:

- a standard UART serial interface, and
- a standard I²C-bus serial interface. The I²C-bus serial interface has byte-oriented master and slave functions allowing communication with the whole family of I²C-bus compatible devices.

8.2 CPU timing

A machine cycle consists of a sequence of 6 states. Each state lasts for two oscillator periods, thus a machine cycle takes 12 oscillator periods or 1 μ s if the oscillator frequency (f_{osc}) is 12 MHz.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

9 MEMORY ORGANIZATION

The P83CL78x has a 16 kbyte Program Memory (ROM) plus 256 bytes of Data Memory (RAM) on-chip. The device has separate address spaces for Program and Data Memory (see Fig.6). Using Ports P0 and P2, the P83CL78x can address up to 128 kbytes of external memory. The CPU generates both read (\overline{RD}) and write (\overline{WR}) signals for external Data Memory accesses, and the read strobe (\overline{PSEN}) for external Program Memory.

9.1 Program memory

The P83CL78x contains 16 kbytes of internal ROM. After reset the CPU begins execution at location 0000H. The lower 16 kbytes of Program Memory can be implemented in either on-chip ROM or external memory. If the \overline{EA} pin is strapped to V_{DD} , then Program Memory fetches from addresses 0000H through to 3FFFH are directed to the internal ROM. Fetches from addresses 4000H through to FFFFH are directed to external ROM. Program Counter values greater than 3FFFH are automatically addressed to external memory regardless of the state of the \overline{EA} pin.

9.2 Data memory

The P83CL78x contains 256 bytes of internal RAM and 34 Special Function Registers (SFRs). The memory map (Fig.6) shows the internal Data Memory space divided into the lower 128 bytes, the upper 128 bytes and the SFR space. Internal RAM locations 0 to 127 are directly and indirectly addressable. Internal RAM locations 128 to 255 are only indirectly addressable. The Special Function Register locations 128 to 255 bytes are only directly addressable.

9.3 Special Function Registers

The upper 128 bytes are the address locations of the Special Function Registers. Figures 7 and 8 show the Special Function Registers space. The SFRs include the port latches, timers, peripheral control, serial I/O registers, and so on. These registers can only be accessed by direct addressing. There are 128 addressable locations in the SFR address space (SFRs with addresses divisible by eight).

9.4 Addressing

The P83CL78x has five methods for addressing source operands:

- Register
- Direct
- Register-indirect
- Immediate
- Base-register plus index-register-indirect.

The first three methods can be used for addressing destination operands. Most instructions have a 'destination/source' field that specifies the data type, addressing methods and operands involved. For operations other than MOVs, the destination operand is also a source operand.

Fig.5 The lower 128 bytes of internal RAM.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

Access to memory addressing is as follows:

- Registers in one of the four register banks through register, direct or register-indirect
- 256 bytes of internal data RAM through direct or register-indirect
- Special Function Registers through direct
- External Data Memory through register-indirect
- Program Memory look-up tables through base-register plus index-register-indirect.

The P83CL78x is classified as an 8-bit device since the internal ROM, RAM, Special Function Registers, Arithmetic Logic Unit and external data bus are all 8-bits wide. It performs operations on bit, nibble, byte and double-byte data types.

Facilities are available for byte transfer, logic and integer arithmetic operations. Data transfer, logic and conditional branch operations can be performed directly on Boolean variables to provide excellent bit handling.

10 I/O FACILITIES

10.1 Ports

The P83CL78x has 32 I/O lines treated as 32 individually addressable bits or as four parallel 8-bit ports. To enable a port pin alternative function, the port bit latch in its SFR must contain a logic 1. The alternative functions are detailed below:

Port 0 Provides the multiplexed low-order address and data bus for expanding the device with standard memories and peripherals.

Port 1 Used for a number of special functions:

- Provides the inputs for the eight external interrupts: INT2 to INT9
- External activation of Timer 2: T2
- The I²C-bus interface: SCL and SDA.

Port 2 Provides the high-order address when expanding the device with external Program or Data memory.

Port 3 Pins can be configured individually to provide:

- External interrupt request inputs: $\overline{\text{INT1}}$ and $\overline{\text{INT0}}$
- Timer/counter inputs: T1 and T0
- Control signals to read and write to external memories: $\overline{\text{RD}}$ and $\overline{\text{WR}}$
- UART asynchronous input and output (RXD and TXD); or UART synchronous I/O and clock lines (data and clock).¹

Each port consists of a latch (SFRs P0 to P3), an output driver and input buffer. Ports 1, 2 and 3 have internal pull-ups (except P1.6 and P1.7). Figure 9(a) shows that the strong transistor 'p1' is turned on for only 2 oscillator periods after a LOW-to-HIGH transition in the port latch. When on, it turns on p3 (a weak pull-up) through the inverter. This inverter and p3 form a latch which holds the logic 1. In Port 0 the pull-up 'p1' is only on when emitting logic 1s for external memory access. Writing a logic 1 to a Port 1 bit latch leaves both output transistors switched off so that the pin can be used as a high-impedance input.

10.2 Port options

30 of the 32 port pins (excluding P1.6 and P1.7 with option 2S only) may be individually configured with one of the following options. These options are also shown in Fig.9.

Option 1 Standard Port; quasi-bidirectional I/O with pull-up. The strong booster pull-up 'p1' is turned on for two oscillator periods after a

LOW-to-HIGH transition in the port latch; Fig.9(a).

Option 2 Open-drain; quasi-bidirectional I/O with n-channel open-drain output. Use as an output requires the connection of an external pull-up resistor; Fig.9(b).

Option 3 Push-Pull; output with drive capability in both polarities. Under this option, pins can only be used as outputs; Fig.9(c).

10.3 Port 0 options

The definition of port options for Port 0 is slightly different. Two cases are considered. First, access to external memory ($\overline{\text{EA}} = 0$ or access above the built-in memory boundary) and second, I/O accesses.

10.3.1 EXTERNAL MEMORY ACCESSES

Option 1 True logic 0 and logic 1 are written as address to the external memory (strong pull-up to be used).

Option 2 An external pull-up resistor is required for external accesses.

Option 3 Not allowed for external memory accesses as the port can only be used as output.

10.3.2 I/O ACCESSES

Option 1 When writing a logic 1 to the port latch, the strong pull-up 'p1' will be on for 2 oscillator periods. No weak pull-up exists. Without an external pull-up, this option can be used as a high-impedance input.

Option 2 Open-drain; quasi-directional I/O with n-channel open-drain output. Use as an output requires the connection of an external pull-up resistor. See Fig.9(b).

Option 3 Push-Pull; output with drive capability in both polarities. Under this option pins can only be used as outputs. See Fig.9(c).

10.4 SET/RESET options

Individual mask selection of the post-reset state is available with any of the above pins. The required selection is made by appending 'S' or 'R' to Options 1, 2, or 3 above.

Option R RESET, at reset this pin will be initialized LOW.

Option S SET, at reset this pin will be initialized HIGH.

P83CL781; P83CL782

11 TIMER/EVENT COUNTERS

The P83CL78x contains three 16-bit timer/event counter registers; Timer 0, Timer 1 and Timer 2 which can perform the following functions:

- Measure time intervals and pulse durations
- Count events
- Generate interrupt requests.

In the 'Timer' operating mode the register is incremented every machine cycle. Since a machine cycle consists of 12 oscillator periods, the count rate is $\frac{1}{12} \times f_{osc}$.

In the 'Counter' operating mode, the register is incremented in response to a HIGH-to-LOW transition. Since it takes 2 machine cycles (24 oscillator periods) to recognize a HIGH-to-LOW transition, the maximum count rate is $\frac{1}{24} \times f_{osc}$. To ensure a given level is sampled, it should be held for at least one complete machine cycle.

11.1 Timer 0 and Timer 1

Timer 0 and Timer 1 can be programmed independently to operate in four modes:

Mode 0 8-bit timer or 8-bit counter each with divide-by-32 prescaler.

Mode 1 16-bit time-interval or event counter.

Mode 2 8-bit time-interval or event counter with automatic reload upon overflow.

Mode 3 Timer 0 establishes TL0 and TH0 as two separate counters.

11.2 Timer T2

Timer T2 is a 16-bit timer/counter that can operate (like Timer 0 and 1) either as a timer or as an event counter. These functions are selected by the state of the $\overline{C/T2}$ bit in the T2CON register; see Tables 1 and 2.

Three operating modes are available Capture, Auto-reload and Baud Rate Generator, which also are selected via the T2CON register; see Table 3.

11.2.1 CAPTURE MODE

Figure 10 shows the Capture mode. Two options in this mode, may be selected by the EXEN2 bit in T2CON:

- If EXEN2 = 0, then Timer 2 is a 16-bit timer or counter which upon overflowing sets the Timer 2 overflow bit TF2, this may then be used to generate an interrupt.
- If EXEN2 = 1, Timer 2 operates as described above but with the additional feature that a HIGH-to-LOW transition at external input T2EX causes the current value in TL2 and TH2 to be captured into registers RCAP2L and RCAP2H respectively. In addition, the transition at T2EX causes the EXF2 bit in T2CON to be set; this may also be used to generate an interrupt.

11.2.2 AUTO-RELOAD MODE

Figure 11 shows the Auto-reload mode. Also two options in this mode are selected by the EXEN2 bit in T2CON:

- If EXEN2 = 0, then when Timer 2 rolls over, it sets the TF2 bit but also causes the Timer 2 registers to be reloaded with the 16-bit value held in registers RCAP2L and RCAP2H. The 16-bit value held in these registers is preset by software.
- If EXEN2 = 1, Timer 2 operates as described above but with the additional feature that a HIGH-to-LOW transition at external input T2EX will also trigger the 16-bit reload and set the EXF2 bit.

11.2.3 BAUD RATE GENERATOR MODE

The Baud Rate Generator mode is selected when RTCLK = 1. It will be described in conjunction with the serial port (UART); see Section 14.3.2.

11.3 Timer/Counter 2 Control Register (T2CON)

Table 1 Timer/Counter 2 Control Register (SFR address C8H)

7	6	5	4	3	2	1	0
TF2	EXF2	GF2	RTCLK	EXEN2	TR2	C/T $\overline{2}$	CP/RL $\overline{2}$

Table 2 Description of T2CON bits

BIT	SYMBOL	DESCRIPTION
7	TF2	Timer 2 overflow flag. Set by a Timer 2 overflow and must be cleared by software. TF2 will not be set when RTCLK = 1.
6	EXF2	Timer 2 external flag. Set when either a capture or reload is caused by a negative transition on T2EX and when EXEN2 = 1. When Timer T2 interrupt is enabled, EXF2 = 1 will cause the CPU to vector to Timer 2 interrupt routine. EXF2 must be cleared by software.
5	GF2	General purpose flag bit.
4	RTCLK	Receive/transmit clock flag. When set, causes the UART serial port to use Timer 2 overflow pulses for its receive and transmit clock in Modes 1 and 3. RTCLK = 0 causes Timer 1 overflows to be used for the receive and transmit clock.
3	EXEN2	Timer 2 external enable flag. When set, allows a capture or reload to occur as a result of a negative transition on T2EX, if Timer 2 is not being used to clock the serial port. EXEN2 = 0, causes Timer 2 to ignore events at T2EX.
2	TR2	Start/stop control for Timer 2. TR2 = 1 starts the timer.
1	C/T $\overline{2}$	Timer or counter select for Timer 2. C/T $\overline{2}$ = 0 selects the internal timer with a clock frequency of $\frac{1}{12} \times f_{osc}$. C/T $\overline{2}$ = 1 selects the external event counter; negative edge triggered.
0	CP/RL $\overline{2}$	Capture/Reload flag. When set, captures will occur on negative transitions at T2EX, if EXEN2 = 1. When cleared, auto-reloads will occur either with Timer 2 overflows or negative transitions at T2EX when EXEN2 = 1. When RTCLK = 1, this bit is ignored and the timer is forced to auto-reload on a Timer 2 overflow.

12 REDUCED POWER MODES

There are two software-selectable modes which further reduce power consumption: 'Idle' and 'Power-down'.

12.1 Idle mode

Operation in Idle mode permits the interrupt, serial ports and timer blocks to continue to function while the clock to the CPU is halted.

Idle mode is entered by setting the IDL bit in the Power Control Register (PCON.0, see Table 5). The instruction that sets IDL is the last instruction executed in the normal operating mode before the Idle mode is activated.

Once in the Idle mode, the CPU status is preserved along with the Stack Pointer, Program Counter, Program Status Word and Accumulator. The RAM and all other registers maintain their data during Idle mode. The status of the external pins during Idle mode is shown in Table 4.

The following functions remain active during the Idle mode:

- Timer 0, Timer 1 and Timer 2
- UART, I²C-bus interface
- External interrupt.

These functions may generate an interrupt or reset; thus ending the Idle mode.

There are two ways to terminate the Idle mode:

1. Activation of any enabled interrupt will cause PCON.0 to be cleared by hardware thus terminating the Idle mode. The interrupt is serviced, and following the RETI instruction, the next instruction to be executed will be the one following the instruction that put the device in the Idle mode. The flag bits GF0 and GF1 may be used to determine whether the interrupt was received during normal execution or during the Idle mode. For example, the instruction that writes to PCON.0 can also set or clear one or both flag bits. When the Idle mode is terminated by an interrupt, the service routine can examine the status of the flag bits.
2. The second way of terminating the Idle mode is with an external hardware reset, or an internal reset caused by an overflow of Timer T2. Since the oscillator is still running, the hardware reset is required to be active for two machine cycles (24 oscillator periods) to complete the reset operation. Reset redefines all SFRs but does not affect the on-chip RAM.

12.2 Power-down mode

Operation in Power-down mode freezes the oscillator. The internal connections which link both Idle and Power-down signals to the clock generation circuit are shown in Fig.12.

Power-down mode is entered by setting the PD bit in the Power Control Register (PCON.1, see Table 5).

The instruction that sets PD is the last executed prior to going into the Power-down mode.

Once in the Power-down mode, the oscillator is stopped. The contents of the on-chip RAM and the SFRs are preserved. The port pins output the value held by their respective SFRs. ALE and PSEN are held LOW.

In the Power-down mode, V_{DD} may be reduced to minimize circuit power consumption. The supply voltage must not be reduced until the Power-down mode is entered, and must be restored before the hardware reset is applied which will free the oscillator. Reset should not be released until the oscillator has restarted and stabilized.

12.3 Wake-up from Power-down mode

When in Power-down mode the controller can be woken-up with either the external interrupts INT2 to INT9, or a reset operation. The wake-up operation has two basic approaches as explained in Section 12.3.1; 12.3.2 and illustrated in Fig.13.

12.3.1 WAKE-UP USING INT2 TO INT9

If any of the interrupts INT2 to INT9 are enabled, the device can be woken-up from the Power-down mode with the external interrupts. To ensure that the oscillator is stable before the controller restarts, the internal clock will remain inactive for 1536 oscillator periods. This is controlled by an on-chip delay counter.

12.3.2 WAKE-UP USING RST

To wake-up the P83CL78x, the RST pin must be kept HIGH for a minimum of 24 periods. The on-chip delay counter is inactive. The user must ensure that the oscillator is stable before any operation is attempted.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

12.4 Status of external pins

The status of the external pins during Idle and Power-down mode is shown in Table 4. If the Power-down mode is activated whilst accessing external Program Memory, the port data that is held in the Special Function Register P2 is restored to Port 2.

If the data is a logic 1, the port pin is held HIGH during the Power-down mode by the strong pull-up transistor 'p1'; see Fig.9(a).

Table 4 Status of external pins during Idle and Power-down modes

MODE	MEMORY	ALE	PSEN	PORT 0	PORT 1	PORT 2	PORT 3
Idle	internal	1	1	port data	port data	port data	port data
Idle	external	1	1	floating	port data	address	port data
Power-down	internal	0	0	port data	port data	port data	port data
Power-down	external	0	0	floating	port data	port data	port data

12.5 Power Control Register (PCON)

The reduced power modes are activated by software using this Special Function Register. PCON is not bit addressable.

Table 5 Power Control Register (SFR address 87H)

7	6	5	4	3	2	1	0
SMOD	–	–	–	GF1	GF0	PD	IDL

Table 6 Description of PCON bits

BIT	SYMBOL	FUNCTION
PCON.7	SMOD	Double Baud rate bit. When set to a logic 1 the baud rate is doubled when the serial port SIO0 is being used in modes 1, 2 or 3.
PCON.6	–	Reserved
PCON.5	–	Reserved
PCON.4	–	Reserved
PCON.3	GF1	General purpose flag bit
PCON.2	GF0	General purpose flag bit
PCON.1	PD	Power-down bit. Setting this bit activates the Power-down mode; see note 1.
PCON.0	IDL	Idle mode bit. Setting this bit activates the Idle mode; see note 1.

Note

1. If logic 1s are written to PD and IDL at the same time, PD takes precedence. The reset value of PCON is (0XX00000).

13 I²C-BUS SERIAL I/O

The serial port supports the twin line I²C-bus, which consists of a serial data line (SDA) and a serial clock line (SCL). These lines also function as the I/O port lines P1.7 and P1.6 respectively.

The system is unique because data transport, clock generation, address recognition and bus control arbitration are all controlled by hardware.

The I²C-bus serial I/O has complete autonomy in byte handling and operates in 4 modes:

- Master transmitter
- Master receiver
- Slave transmitter
- Slave receiver.

These functions are controlled by the Serial Control Register S1CON. S1STA is the Status Register whose contents may also be used as a vector to various service routines. S1DAT is the Data Shift Register and S1ADR is the Slave Address Register. Slave address recognition is performed by on-chip hardware.

Figure 14 is the block diagram of the I²C-bus serial I/O.

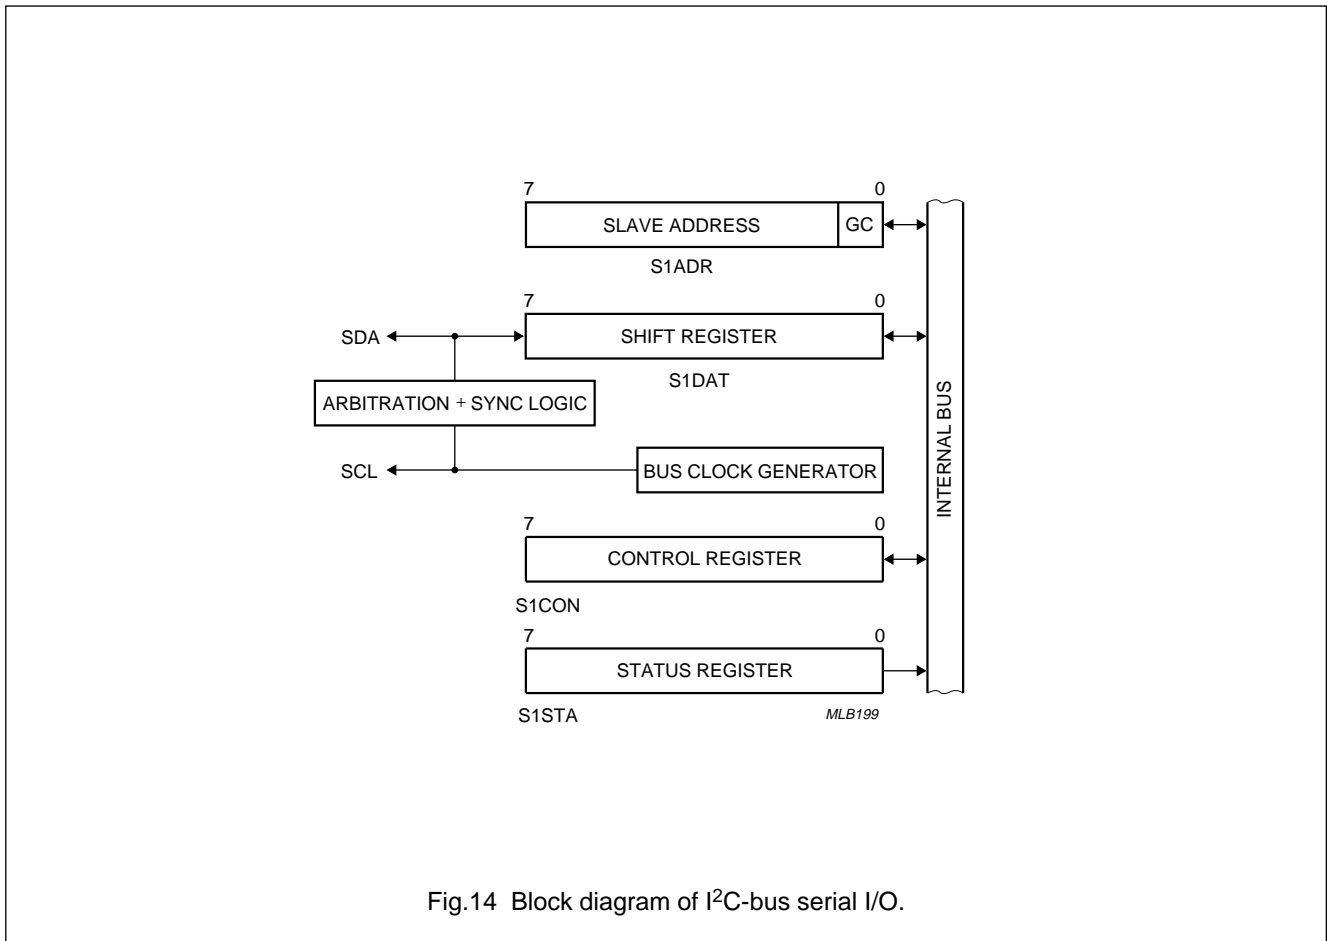

Fig.14 Block diagram of I²C-bus serial I/O.

13.1 Serial Control Register (S1CON)

Table 7 Serial Control Register (SFR address D8H)

7	6	5	4	3	2	1	0
CR2	ENS1	STA	STO	SI	AA	CR1	CR0

Table 8 Description of S1CON bits

BIT	SYMBOL	DESCRIPTION
7	CR2	This bit along with bits CR1 (S1CON.1) and CR0 (S1CON.0) determines the serial clock frequency when SIO is in the Master mode. See Table 9.
6	ENS1	ENABLE serial I/O. When ENS1 = 0, the serial I/O is disabled. SDA and SCL outputs are in the high impedance state; P1.6 and P1.7 function as open-drain ports. When ENS1 = 1, the serial I/O is enabled. Output port latches P1.6 and P1.7 must be set to logic 1.
5	STA	START flag. When this bit is set in Slave mode, the SIO hardware checks the status of the I ² C-bus and generates a START condition if the bus is free or after the bus becomes free. If STA is set while the SIO is in Master mode, SIO will generate a repeated START condition.
4	STO	STOP flag. With this bit set while in Master mode a STOP condition is generated. When a STOP condition is detected on the I ² C-bus, the SIO hardware clears the STO flag. STO may also be set in Slave mode in order to recover from an error condition. In this case no STOP condition is transmitted to the I ² C-bus. However, the SIO hardware behaves as if a STOP condition has been received and releases the SDA and SCL. The SIO then switches to the not addressed slave receiver mode. The STOP flag is cleared by the hardware.
3	SI	SIO interrupt flag. This flag is set, and an interrupt is generated, after any of the following events occur: <ul style="list-style-type: none"> • A start condition is generated in Master mode • Own slave address has been received during AA = 1 • The general call address has been received while GC (S1ADR.0) = 1 and AA = 1 • A data byte has been received or transmitted in Master mode (even if arbitration is lost) • A data byte has been received or transmitted as selected slave • A Stop or Start condition is received as selected slave receiver or transmitter.
2	AA	Assert Acknowledge. When this bit is set, an acknowledge (low level to SDA) is returned during the acknowledge clock pulse on the SCL line when: <ul style="list-style-type: none"> • Own slave address is received • General call address is received; GC (S1ADR.0) = 1 • A data byte is received while the device is programmed to be a Master Receiver • A data byte is received while the device is a selected Slave Receiver. When this bit is reset, no acknowledge is returned. Consequently, no interrupt is requested when the own slave address or general call address is received.
1	CR1	These two bits along with the CR2 (S1CON.7) bit determine the serial clock frequency when SIO is in the Master mode. See Table 9.
0	CR0

13.2 Serial Status Register (S1STA)

S1STA is a read-only register. The contents of this register may be used as a vector to a service routine. This optimizes the response time of the software and consequently that of the I²C-bus. The status codes for all possible modes of the I²C-bus interface are given in Tables 12 to 16.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

14 STANDARD SERIAL INTERFACE SIO0: UART

This serial port is full duplex which means that it can transmit and receive simultaneously. It is also receive-buffered and can commence reception of a second byte before a previously received byte has been read from the register. (However, if the first byte has not been read by the time the reception of the second byte is complete, one of the bytes will be lost). The serial port receive and transmit registers are both accessed via the Special Function Register S0BUF. Writing to S0BUF loads the transmit register and reading S0BUF accesses a physically separate receive register.

The serial port can operate in 4 modes:

- Mode 0 Serial data enters and exits through RXD. TXD outputs the shift clock. Eight bits are transmitted/received (LSB first). The baud rate is fixed at $\frac{1}{12} \times f_{osc}$.
- Mode 1 10 bits are transmitted (through TXD) or received (through RXD): a start bit (logic 0), 8 data bits (LSB first), and a stop bit (logic 1). On receive, the stop bit goes into RB8 in Special Function Register S0CON. The baud rate is variable.
- Mode 2 11 bits are transmitted (through TXD) or received (through RXD): start bit (logic 0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (logic 1). On transmit, the 9th data bit (TB8 in S0CON) can be assigned the value of a logic 0 or logic 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. On receive, the 9th data bit goes into RB8 in S0CON, while the stop bit is ignored. The baud rate is programmable to either $\frac{1}{32}$ or $\frac{1}{64} \times f_{osc}$.
- Mode 3 11 bits are transmitted (through TXD) or received (through RXD): a start bit (logic 0), 8 data bits (LSB first), a programmable 9th data bit and a stop bit (logic 1). In fact, Mode 3 is the same as Mode 2 in all respects except baud rate. The baud rate in Mode 3 is variable.

In all four modes, transmission is initiated by any instruction that uses S0BUF as a destination register. Reception is initiated in Mode 0 by the condition RI = 0 and REN = 1. Reception is initiated in the other modes by the incoming start bit if REN = 1.

14.1 Multiprocessor communications

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th bit goes into RB8. The following bit is the stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated, but only if RB8 = 1. This feature is enabled by setting bit SM2 in S0CON. One use of this feature, in multiprocessor systems, is as follows.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is HIGH in an address byte and LOW in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be sent. The slaves that were not being addressed leave their SM2 bits set and go on about their business, ignoring the coming data bytes.

SM2 has no effect in Mode 0, and in Mode 1 can be used to check the validity of the stop bit. In a Mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

14.2 Serial Port Control and Status Register (S0CON)

The Serial Port Control and Status Register is the Special Function Register S0CON. The register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8), and the serial port interrupt bits (TI and RI).

Table 21 Serial Port Control Register (address 98H)

7	6	5	4	3	2	1	0
SM0	SM1	SM2	REN	TB8	RB8	TI	RI

Table 22 Description of S0CON bits

BIT	SYMBOL	DESCRIPTION
7	SM0	These bits are used to select the serial port mode; see Table 23.
6	SM1	
5	SM2	Enables the multiprocessor communication feature in Modes 2 and 3. In these modes, if SM2 = 1, then RI will not be activated if the received 9 th data bit (RB8) is a logic 0. In Mode 1, if SM2 = 1, then RI will not be activated unless a valid stop bit was received. In Mode 0, SM2 should be a logic 0.
4	REN	Enables serial reception and is set by software to enable reception, and cleared by software to disable reception.
3	TB8	Is the 9 th data bit that will be transmitted in Modes 2 and 3. Set or cleared by software as desired.
2	RB8	In Modes 2 and 3, is the 9 th data bit received. In Mode 1, if SM2 = 0 then RB8 is the stop bit that was received. In Mode 0, RB8 is not used.
1	TI	The transmit interrupt flag. Set by hardware at the end of the 8 th bit time in Mode 0, or at the beginning of the stop bit time in the other modes, in any serial transmission. Must be cleared by software.
0	RI	The receive interrupt flag. Set by hardware at the end of the 8 th bit time in Mode 0, or halfway through the stop bit time in the other modes, in any serial transmission (except see SM2). Must be cleared by software.

Table 23 Selection of the serial port modes

SM0	SM1	MODE	DESCRIPTION	BAUD RATE
0	0	Mode 0	Shift register	$\frac{1}{12} \times f_{osc}$
0	1	Mode 1	8-bit UART	variable
1	0	Mode 2	9-bit UART	$\frac{1}{32}$ or $\frac{1}{64} \times f_{osc}$
1	1	Mode 3	9-bit UART	variable

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

14.3 Baud rates

The baud rate in Mode 0 is fixed and may be calculated as:

$$\text{Baud Rate} = \frac{f_{\text{osc}}}{12}$$

The baud rate in Mode 2 depends on the value of the SMOD bit in Special Function Register PCON and may be calculated as:

$$\text{Baud Rate} = \frac{2^{\text{SMOD}}}{64} \times f_{\text{osc}}$$

- If SMOD = 0 (value on reset), the baud rate is $\frac{1}{64} \times f_{\text{osc}}$
- If SMOD = 1, the baud rate is $\frac{1}{32} \times f_{\text{osc}}$

The baud rates in Modes 1 and 3 are determined by the Timer 1 or Timer 2 overflow rate.

14.3.1 USING TIMER 1 TO GENERATE BAUD RATES

When Timer 1 is used as the Baud Rate Generator, the baud rates in Modes 1 and 3 are determined by the Timer 1 overflow rate and the value of the SMOD bit as follows:

$$\text{Baud Rate} = \frac{2^{\text{SMOD}}}{32} \times \text{Timer 1 Overflow Rate.}$$

The Timer 1 interrupt should be disabled in this application. The Timer itself can be configured for either 'timer' or 'counter' operation in any of its 3 running modes. In most typical applications, it is configured for 'timer' operation, in the Auto-reload mode (high nibble of TMOD = 0010B). In this case the baud rate is given by the formula:

$$\text{Baud Rate} = \frac{2^{\text{SMOD}}}{32} \times \frac{f_{\text{osc}}}{\{12 \times (256 - \text{TH1})\}}$$

By configuring Timer 1 to run as a 16-bit timer (high nibble of TMOD = 0001B), and using the Timer 1 interrupt to do a 16-bit software reload, very low baud rates can be achieved. Table 24 lists commonly used baud rates and how they can be obtained from Timer 1.

Table 24 Commonly used baud rates generated by Timer 1

BAUD RATE (kb/s)	f _{osc} (MHz)	SMOD	C/T	TIMER 1 MODE	RELOAD VALUE
1000.0 ⁽¹⁾	12.000	X ⁽²⁾	X	X	X
375.0 ⁽³⁾	12.000	1	X	X	X
62.5 ⁽⁴⁾	12.000	1	0	Mode 2	FFH
19.2	11.059	1	0	Mode 2	FDH
9.6	11.059	0	0	Mode 2	FDH
4.8	11.059	0	0	Mode 2	FAH
2.4	11.059	0	0	Mode 2	F4H
1.2	11.059	0	0	Mode 2	E8H
137.5	11.986	0	0	Mode 2	1DH
110.0	6.000	0	0	Mode 2	72H
110.0	12.000	0	0	Mode 1	FEEBH

1. Maximum in Mode 0.
2. X = don't care.
3. Maximum in Mode 2.
4. Maximum in Modes 1 and 3.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

14.3.2 USING TIMER 2 TO GENERATE BAUD RATES

Timer 2 is selected as a Baud Rate Generator by setting the RTCLK bit in T2CON. The Baud Rate Generator mode is similar to the Auto-reload mode, in that a roll-over in TH2 causes Timer 2 registers to be reloaded with the 16-bit value held in the registers RCAP2H and RCAP2L, which are preset by software. Baud rates in Modes 1 and 3 are determined by Timer 2's overflow rate as specified below.

$$\text{Baud Rate} = \frac{\text{Timer 2 Overflow Rate}}{16}$$

The Timer 2 can be configured for either 'timer' or 'counter' operation. In the most typical applications, it is configured for 'timer' operation (C/T2 = 0). 'Timer' operation is slightly different for Timer 2 when it is being used as a Baud Rate Generator. Normally, as a timer it would increment every machine cycle at a frequency of $\frac{1}{12} \times f_{osc}$. However, as a Baud Rate Generator it increments every state time at a frequency of $\frac{1}{2} \times f_{osc}$. In this case the baud rate in Modes 1 and 3 is determined as:

$$\text{Baud Rate} = \frac{f_{osc}}{32 \times \{65536 - (\text{RCAP2H}; \text{RCAP2L})\}}$$

Where (RCAP2H; RCAP2L) is the content of registers RCAP2H and RCAP2L taken as a 16-bit unsigned integer.

The Baud Rate Generator mode for Timer 2 is shown in Fig.15. This figure is only valid if RTCLK = 1. At roll-over TH2 does not set the TF2 bit in T2CON and therefore, will not generate an interrupt. Consequently, the Timer 2 interrupt does not need to be disabled when in the Baud Rate Generator mode. If EXEN2 is set, a HIGH-to-LOW transition on T2EX will set the EXF2 bit, also in T2CON, but will not cause a reload from (RCAP2H; RCAP2L) to (TH2, TL2). Therefore, in this mode T2EX may be used as an additional external interrupt.

When Timer 2 is operating as a timer (TR2 = 1), in the Baud Rate Generator mode, registers TH2 and TL2 should not be accessed (read or write). Under these conditions the timer is being incremented every state time and therefore the results of a read or write may not be accurate. The registers RCAP2H and RCAP2L however, may be read but not written to. A write might overlap a reload and cause write and/or reload errors. If a write operation is required, Timer 2 or RCAP2H/RCAP2L should first be turned off by clearing the TR2 bit.

15 INTERRUPT SYSTEM

External events and the real-time-driven on-chip peripherals require service by the CPU at unpredictable times. To tie the asynchronous activities of these functions to normal program execution a multiple-source, two-priority-level, nested interrupt system is provided. The system is shown in Fig.24. The P83CL78x acknowledges interrupt requests from fifteen sources as follows:

- INT0 to INT9
- Timer 0, Timer 1 and Timer 2
- I²C-bus serial I/O
- UART.

Each interrupt vectors to a separate location in Program Memory for its service routine. Each source can be individually enabled or disabled by its corresponding bit in the Interrupt Enable Registers (IEN0 and IEN1). The priority level is selected via the Interrupt Priority Registers (IP0 and IP1). All enabled sources can be globally disabled or enabled.

15.1 External interrupts INT2 to INT9

Port 1 lines serve an alternative purpose as eight additional interrupts INT2 to INT9. When enabled, each of these lines may wake-up the device from the Power-down mode. Using the Interrupt Polarity Register (IX1), each pin may be initialized to be either active HIGH or active LOW. IRQ1 is the Interrupt Request Flag Register. If the interrupt is enabled, each flag will be set on an interrupt request but must be cleared by software, i.e. via the interrupt software or when the interrupt is disabled.

Port 1 interrupts are level-sensitive. A Port 1 interrupt will be recognized when a level (HIGH or LOW depending on the Interrupt Polarity Register) on P1.n is held active for at least one machine cycle. The interrupt request is not serviced until the next machine cycle. Figure 25 shows the external interrupt system.

15.2 Interrupt priority

Each interrupt source can be set to either a high priority or to a low priority. If a low priority interrupt is received simultaneously with a high priority interrupt, the high priority interrupt will be dealt with first.

If interrupts of the same priority are requested simultaneously, the processor will branch to the interrupt polled first, according to the sequence shown in Table 25 and in Fig.24. The 'vector address' is the ROM location where the appropriate interrupt service routine starts.

Table 25 Interrupt vector polling sequence

SYMBOL	VECTOR ADDRESS (HEX)	SOURCE
X0 (first)	0003	External 0
S1	002B	I ² C port
X5	0053	External 5
T0	000B	Timer 0
T2	0033	Timer 2
X6	005B	External 6
X1	0013	External 1
X2	003B	External 2
X7	0063	External 7
T1	001B	Timer 1
X3	0043	External 3
X8	006B	External 8
SO	0023	UART
X4	004B	External 4
X9 (last)	0073	External 9

A low priority interrupt routine can only be interrupted by a high priority interrupt. A high priority interrupt routine cannot be interrupted.

16 OSCILLATOR CIRCUITRY

The on-chip oscillator circuitry of the P8xCL580 is a single-stage inverting amplifier biased by an internal feedback resistor. The oscillator circuit is shown in Fig.26. For operation as a standard quartz oscillator, no external components are needed, except for the 32 kHz option. When using external capacitors, ceramic resonators, coils and RC networks to drive the oscillator, five different configurations are supported (see Table 39 and Fig.26).

In the Power-down mode the oscillator is stopped and XTAL1 is pulled HIGH. The oscillator inverter is switched off to ensure no current will flow regardless of the voltage at XTAL1, for configurations (a), (b), (c), (d), (e) and (g) of Fig.26.

To drive the device with an external clock source, apply the external clock signal to XTAL1, and leave XTAL2 to float, as shown in Fig.26(f). There are no requirements on the duty cycle of the external clock, since the input to the internal clocking circuitry is buffered by a flip-flop.

Various oscillator options are provided for optimum on-chip oscillator performance; these are specified in Table 40 and shown in Fig.26. The required option should be stated when ordering.

Table 39 Oscillator options

OPTION	APPLICATION
Oscillator 1	For 32 kHz clock applications with external trimmer for frequency adjustment. A 4.7 MΩ bias resistor is needed for use in parallel with the crystal; see Fig.26(c).
Oscillator 2	Low-power, low-frequency operations using LC components; see Fig.26(e).
Oscillator 3	Medium frequency range applications.
Oscillator 4	High frequency range applications.
RC oscillator	RC oscillator configuration; see Figs 26(g) and 28.

P83CL781; P83CL782

17 RESET

To initialize the P83CL78x a reset is performed by either of two methods:

- Applying an external signal to the RST pin
- Via Power-on reset circuitry.

The reset state of the port pins is mask-programmable and can be defined by the user. The standard reset value for Ports 0 to 3 is FFH. A reset leaves the internal registers as shown in Chapter 18.

17.1 External reset using the RST pin

The reset input for the P83CL78x is RST. A Schmitt trigger is used at the input for noise rejection. The output of the Schmitt trigger is sampled by the reset circuitry every machine cycle. A reset is accomplished by holding the RST pin HIGH for at least two machine cycles (24 oscillator periods) while the oscillator is running. The CPU responds by executing an internal reset. Port pins adopt their reset state immediately after the RST goes HIGH. During reset, ALE and PSEN are held HIGH.

The external reset is asynchronous to the internal clock. The RST pin is sampled during state 5, phase 2 of every machine cycle. After a HIGH is detected at the RST pin, an internal reset is repeated until RST goes LOW. The internal RAM is not affected by reset. When V_{DD} is turned on, the RAM contents are indeterminate.

17.2 Power-on reset

The device contains on-chip circuitry which switches the port pins to the customer defined logic level as soon as V_{DD} exceeds 1.3 V; if the mask option 'ON' has been chosen. As soon as the minimum supply voltage is reached, the oscillator will start up. However, to ensure that the oscillator is stable before the controller starts, the clock signals are gated away from the CPU for a further 1536 oscillator periods. A hysteresis of approximately 50 mV at a typical power-on switching level of 1.3 V will ensure correct operation. See Fig.32.

The on-chip Power-on reset circuitry can also be switched off via the mask option 'OFF'. This option reduces the Power-down current to typically 800 nA and can be chosen if external reset circuitry is used. For applications not requiring the internal reset, option 'OFF' should be chosen.

An automatic reset can be obtained by connecting the RST pin to V_{DD} via a 10 μF capacitor. At power-on, the voltage on the RST pin is equal to V_{DD} minus the capacitor voltage, and decreases from V_{DD} as the capacitor charges through the internal resistor (R_{RST}) to ground. The larger the capacitor, the more slowly V_{RST} decreases. V_{RST} must remain above the lower threshold of the Schmitt trigger long enough to effect a complete reset. The time required is the oscillator start-up time, plus 2 machine cycles. The Power-on reset circuitry is shown in Fig.31.

Notes

1. Bit addressable register.
2. Port reset state determined by the customer.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

19 INSTRUCTION SET

The P83CL78x uses a powerful instruction set which permits the expansion of on-chip CPU peripherals and optimizes byte efficiency and execution speed. Assigned opcodes add new high-power operation and permit new addressing modes. The instruction set consists of 49 single-byte, 46 two-byte and 16 three-byte instructions. When using a 12 MHz oscillator, 64 instructions execute in 1 μ s and 45 instructions execute in 2 μ s. Multiply and divide instructions execute in 4 μ s.

For the description of the **Data Addressing modes** and **Hexadecimal opcode cross-reference** see Table 46.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

Table 46 Description of the mnemonics in the Instruction set

MNEMONIC	DESCRIPTION
Data addressing modes	
Rr	Working register R0-R7.
direct	128 internal RAM locations and any special function register (SFR).
@Ri	Indirect internal RAM location addressed by register R0 or R1 of the actual register bank.
#data	8-bit constant included in instruction.
#data 16	16-bit constant included as bytes 2 and 3 of instruction.
bit	Direct addressed bit in internal RAM or SFR.
addr16	16-bit destination address. Used by LCALL and LJMP. The branch will be anywhere within the 64 kbytes Program Memory address space.
addr11	11-bit destination address. Used by ACALL and AJMP. The branch will be within the same 2 kbytes page of Program Memory as the first byte of the following instruction.
rel	Signed (two's complement) 8-bit offset byte. Used by SJMP and all conditional jumps. Range is -128 to +127 bytes relative to first byte of the following instruction.
Hexadecimal opcode cross-reference	
*	8, 9, A, B, C, D, E, F.
•	1, 3, 5, 7, 9, B, D, F.
♦	0, 2, 4, 6, 8, A, C, E.

I _{LI}	input leakage current	V _{SS} < V _I < V _{DD} ; note 7	–	–	±10	μA
Outputs						
I _{OL}	LOW level output current; except SDA and SCL	V _{DD} = 5 V; V _{OL} = 0.4 V	1.6	–	–	mA
		V _{DD} = 2.5 V; V _{OL} = 0.4 V	0.7	–	–	mA
I _{OL1}	LOW level output current; SDA and SCL	V _{DD} = 5 V; V _{OL} = 0.4 V	3.0	–	–	mA
I _{OH}	HIGH level output current (push-pull options only)	V _{DD} = 5 V; V _{OH} = V _{DD} – 0.4 V	–1.6	–	–	mA
		V _{DD} = 2.5 V; V _{OH} = V _{DD} – 0.4 V	–0.7	–	–	mA
R _{RST}	RST pull-down resistor		10	–	200	kΩ

Notes

- Capacitive loading on Ports 0 and 2 may cause spurious noise pulses to be superimposed on the LOW level output voltage of ALE, Port 1 and Port 3 pins when these make a HIGH-to-LOW transition during bus operations. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins make HIGH-to-LOW transitions during bus operations. In the most adverse conditions (capacitive loading >100 pF), the noise pulse on the ALE line may exceed 0.8 V. In such events it may be required to qualify ALE with a Schmitt trigger, or use an address latch with a Schmitt trigger strobe input.
- Capacitive loading on Ports 0 and 2 may cause the HIGH level output voltage on ALE and $\overline{\text{PSEN}}$ to momentarily fall below the 0.9% of V_{DD} specification when the address bits are stabilizing.
- Circuits with Power-on reset option 'OFF' are tested at V_{DDmin} = 1.8 V; with the 'ON' option (typically 1.3 V) they are tested at V_{DDmin} = 2.3 V.
- The operating supply current is measured with all output pins disconnected; XTAL1 driven with t_r = t_f = 10 ns; V_{IL} = V_{SS}; V_{IH} = V_{DD}; XTAL2 not connected; EA = RST = Port 0 = V_{DD}.
- The Idle mode supply current is measured with all output pins disconnected; XTAL1 driven with t_r = t_f = 10 ns; V_{IL} = V_{SS}; V_{IH} = V_{DD}; XTAL2 not connected; $\overline{\text{EA}}$ = Port 0 = V_{DD}.
- The Power-down current is measured with all output pins disconnected; XTAL1 not connected; $\overline{\text{EA}}$ = Port 0 = V_{DD}; RST = V_{SS}.
- The input threshold voltage of P1.6/SCL and P1.7/SDA meet the I²C-bus specification. Therefore, an input voltage below 0.3V_{DD} will be recognized as a logic 0 and an input voltage above 0.7V_{DD} will be recognized as a logic 1.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

24 SOLDERING

24.1 Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "IC Package Databook" (order code 9398 652 90011).

24.2 DIP

24.2.1 SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ($T_{stg\ max}$). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

24.2.2 REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

24.3 QFP

24.3.1 REFLOW SOLDERING

Reflow soldering techniques are suitable for all QFP packages.

The choice of heating method may be influenced by larger plastic QFP packages (44 leads, or more). If infrared or vapour phase heating is used and the large packages are not absolutely dry (less than 0.1% moisture content by weight), vaporization of the small amount of moisture in them can cause cracking of the plastic body. For more information, refer to the Drypack chapter in our "Quality Reference Handbook" (order code 9398 510 63011).

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary from 50 to 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheat for 45 minutes at 45 °C.

24.3.2 WAVE SOLDERING

Wave soldering is **not** recommended for QFP packages. This is because of the likelihood of solder bridging due to closely-spaced leads and the possibility of incomplete solder penetration in multi-lead devices.

If wave soldering cannot be avoided, the following conditions must be observed:

- **A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.**
- **The footprint must be at an angle of 45° to the board direction and must incorporate solder thieves downstream and at the side corners.**

Even with these conditions, do not consider wave soldering the following packages: QFP52 (SOT379-1), QFP100 (SOT317-1), QFP100 (SOT317-2), QFP100 (SOT382-1) or QFP160 (SOT322-1).

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured. Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

24.3.3 REPAIRING SOLDERED JOINTS

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

Low voltage 8-bit microcontrollers with UART and I²C-bus

P83CL781; P83CL782

25 DEFINITIONS

Data sheet status	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
Limiting values	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
Application information	
Where application information is given, it is advisory and does not form part of the specification.	

26 LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.

27 PURCHASE OF PHILIPS I²C COMPONENTS

Purchase of Philips I²C components conveys a license under the Philips' I²C patent to use the components in the I²C system provided the system conforms to the I²C specification defined by Philips. This specification can be ordered using the code 9398 393 40011.

Low voltage 8-bit microcontrollers with
UART and I²C-bus

P83CL781; P83CL782

NOTES

Low voltage 8-bit microcontrollers with
UART and I²C-bus

P83CL781; P83CL782

NOTES

Philips Semiconductors – a worldwide company

Argentina: see South America

Australia: 34 Waterloo Road, NORTH RYDE, NSW 2113,
Tel. +61 2 9805 4455, Fax. +61 2 9805 4466

Austria: Computerstr. 6, A-1101 WIEN, P.O. Box 213,
Tel. +43 1 60 101, Fax. +43 1 60 101 1210

Belarus: Hotel Minsk Business Center, Bld. 3, r. 1211, Volodarski Str. 6,
220050 MINSK, Tel. +375 172 200 733, Fax. +375 172 200 773
