

## ADVANCE INFORMATION

## DS90C031

### LVDS Quad CMOS Differential Line Driver

#### General Description

The DS90C031 is a quad CMOS differential line driver designed for applications requiring ultra low power dissipation and high data rates. The device is designed to support data rates in excess of 65 MHz utilizing Low Voltage Differential Signaling (LVDS) technology.

The DS90C031 accepts TTL/CMOS input levels and translates them to low voltage (330 mV) differential output signals. In addition the driver supports a TRI-STATE® function that may be used to disable the output stage, disabling the load current, and thus dropping the device to an ultra low idle power state of 7.5 mW typical.

The DS90C031 and companion line receiver (DS90C032) provide a new alternative to high power psuedo-ECL devices for high speed point to point interfaces.

#### Features

- > 65 MHz switching rates
- $\pm 330$  mV differential signaling
- Ultra low power dissipation
- 500 ps maximum differential skew
- 1.8 ns maximum chip to chip skew
- Industrial operating temperature range
- Available in surface mount packaging (SOIC)
- Pin compatible with DS26C31, MB571 and 41LG
- Compatible with IEEE P1596.3 SCI LVDS draft standard

| $t_{PLZ}$                            | Disable Time Low to Z                      |                                                           |     | 5   | 10  | ns    |
| $t_{PZH}$                            | Enable Time Z to High                      |                                                           |     | 5   | 10  | ns    |
| $t_{PZL}$                            | Enable Time Z to Low                       |                                                           |     | 5   | 10  | ns    |

**Note 1:** "Absolute Maximum Ratings" are those values beyond which the safety of the device cannot be guaranteed. They are not meant to imply that the devices should be operated at these limits. The table of "Electrical Characteristics" specifies conditions of device operation.

**Note 2:** Current into device pins is defined as positive. Current out of device pins is defined as negative. All voltages are referenced to ground except:  $V_{OD1}$  and  $\Delta V_{OD1}$ .

**Note 3:** All typicals are given for:  $V_{CC} = +5.0V$ ,  $T_A = +25^\circ C$ .

**Note 4:** Chip to Chip Skew is defined as the difference between the minimum and maximum specified differential propagation delays.
