

## 5MHz, Single and Dual Rail-to-Rail Input-Output (RRIO) Op Amps

The ISL28146 and ISL28246 are low-power single and dual operational amplifiers optimized for single supply operation from 2.4V to 5.5V, allowing operation from one lithium cell or two Ni-Cd batteries. They feature a gain-bandwidth product of 5MHz and are unity-gain stable with a -3dB bandwidth of 13MHz.

These devices feature an Input Range Enhancement Circuit (IREC) which enables them to maintain CMRR performance for input voltages greater than the positive supply. The input signal is capable of swinging 0.25V above a 5.0V supply and to within 10mV from ground. The output operation is rail-to-rail.

The parts draw minimal supply current while meeting excellent DC accuracy, AC performance, noise and output drive specifications. The ISL28146 features an enable pin that can be used to turn the device off and reduce the supply current to only 16µA. Operation is guaranteed over -40°C to +125°C temperature range.

\*Please refer to TB347 for details on reel specifications

NOTE: These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

### Features

- 5MHz gain bandwidth product @  $A_V = 100$
- 13MHz -3db unity gain bandwidth
- 1mA typical supply current (per amplifier)
- 650µV maximum offset voltage
- 16nA typical input bias current
- Down to 2.4V single supply voltage range
- Rail-to-rail input and output
- Enable pin (ISL28146 only)
- -40°C to +125°C operation
- Pb-free (RoHS compliant)

### Applications

- Low-end audio
- 4mA to 20mA current loops
- Medical devices
- Sensor amplifiers
- ADC buffers
- DAC output amplifiers

### Pinouts

**Absolute Maximum Ratings** ( $T_A = +25^\circ\text{C}$ )

Supply Voltage	5.75V
Supply Turn On Voltage Slew Rate	1V/ $\mu\text{s}$
Differential Input Current	5mA
Differential Input Voltage	0.5V
Input Voltage	V- - 0.5V to V+ + 0.5V
ESD Rating	
Human Body Model	.3kV
Machine Model	.300V
Charged Device Model	1500V

**Thermal Information**

## Applications Information

### Introduction

The ISL28146 and ISL28246 are single and dual channel rail-to-rail input, output (RRIO) micropower precision operational amplifiers. The parts are designed to operate from single supply (2.4V to 5.0V) or dual supply ( $\pm 1.2V$  to  $\pm 2.75V$ ). The parts have an input common mode range that extends 0.25V above the positive rail and down to the negative supply rail. The output operation can swing within about 3mV of the supply rails with a 100k $\Omega$  load.

### Rail-to-Rail Input

Many rail-to-rail input stages use two differential input pairs, a long-tail PNP (or PFET) and an NPN (or NFET). Severe penalties have to be paid for this circuit topology. As the input signal moves from one supply rail to another, the operational amplifier switches from one input pair to the other causing drastic changes in input offset voltage and an undesired change in magnitude and polarity of input offset current.

The ISL28146 and ISL28246 achieve input rail-to-rail operation without sacrificing important precision specifications and degrading distortion performance. The devices' input offset voltage exhibits a smooth behavior throughout the entire common-mode input range. The input bias current versus the common-mode voltage range gives an undistorted behavior from typically down to the negative rail and up to 0.25V higher than the V+ rail.

### Rail-to-Rail Output

A pair of complementary MOS devices are used to achieve the rail-to-rail output swing. The NMOS sinks current to swing the output in the negative direction. The PMOS sources current to swing the output in the positive direction. The ISL28146 and ISL28246 with a 100k $\Omega$  load will swing to within 3mV of the positive supply rail and within 3mV of the negative supply rail.

### Results of Over-Driving the Output

Caution should be used when over-driving the output for long periods of time. Over-driving the output can occur in two ways:

1. The input voltage times the gain of the amplifier exceeds the supply voltage by a large value.
2. The output current required is higher than the output stage can deliver. These conditions can result in a shift in the Input Offset Voltage ( $V_{OS}$ ) as much as 1 $\mu V/hr.$  of exposure under these conditions.

### IN+ and IN- Input Protection

All input terminals have internal ESD protection diodes to both positive and negative supply rails, limiting the input voltage to within one diode beyond the supply rails. They also contain back-to-back diodes across the input terminals ("Pin Descriptions" on page 10 - Circuit 1). For applications where the input differential voltage is expected to exceed 0.5V, an

external series resistor must be used to ensure the input currents never exceed 5mA (Figure 36).

FIGURE 36. INPUT CURRENT LIMITING

### Enable/Disable Feature

The ISL28146 offers an  $\overline{EN}$  pin that disables the device when pulled up to at least 2.0V. In the disabled state (output in a high impedance state), the part consumes typically 10 $\mu A$  at room temperature. The  $\overline{EN}$  pin has an internal pull-down. If left open, the  $\overline{EN}$  pin will pull to the negative rail and the device will be enabled by default. When not used, the  $\overline{EN}$  pin should either be left floating or connected directly to the -V pin.

By disabling the part, multiple ISL28146 parts can be connected together as a MUX. In this configuration, the outputs are tied together in parallel and a channel can be selected by the  $\overline{EN}$  pin. The loading effects of the feedback resistors of the disabled amplifier must be considered when multiple amplifier outputs are connected together. Note that feed through from the IN+ to IN- pins occurs on any Mux Amp disabled channel where the input differential voltage exceeds 0.5V (e.g., active channel  $V_{OUT} = 1V$ , while disabled channel  $V_{IN} = GND$ ), so the mux implementation is best suited for small signal applications. If large signals are required, use series IN+ resistors, or a large value  $R_F$ , to keep the feed through current low enough to minimize the impact on the active channel. See "Limitations of the Differential Input Protection" on page 11.

### Limitations of the Differential Input Protection

If the input differential voltage is expected to exceed 0.5V, an external current limiting resistor must be used to ensure the input current never exceeds 5mA. For non-inverting unity gain applications, the current limiting can be via a series IN+ resistor, or via a feedback resistor of appropriate value. For other gain configurations, the series IN+ resistor is the best choice, unless the feedback ( $R_F$ ) and gain setting ( $R_G$ ) resistors are both sufficiently large to limit the input current to 5mA.

Large differential input voltages can arise from several sources:

1. During open loop (comparator) operation. Used this way, the IN+ and IN- voltages don't track, so differentials arise.
2. When the amplifier is disabled but an input signal is still present. An  $R_L$  or  $R_G$  to GND keeps the IN- at GND, while the varying IN+ signal creates a differential voltage. Mux Amp applications are similar, except that the active channel  $V_{OUT}$  determines the voltage on the IN- terminal.
3. When the slew rate of the input pulse is considerably faster than the op amp's slew rate. If the  $V_{OUT}$  can't keep

up with the IN+ signal, a differential voltage results, and visible distortion occurs on the input and output signals. To avoid this issue, keep the input slew rate below 1.9V/μs, or use appropriate current limiting resistors.

Large (>2V) differential input voltages can also cause an increase in disabled I<sub>CC</sub>.

**Using Only One Channel**

The ISL28246 is a dual op amp. If the application only requires one channel, the user must configure the unused channel to prevent it from oscillating. The unused channel will oscillate if the input and output pins are floating. This will result in higher than expected supply currents and possible noise injection into the channel being used. The proper way to prevent this oscillation is to short the output to the negative input and ground the positive input (Figure 37).

FIGURE 37. PREVENTING OSCILLATIONS IN UNUSED CHANNELS

**Current Limiting**

These devices have no internal current-limiting circuitry. If the output is shorted, it is possible to exceed the Absolute Maximum Rating for output current or power dissipation, potentially resulting in the destruction of the device.

**Power Dissipation**

It is possible to exceed the +125°C maximum junction temperatures under certain load and power-supply conditions. It is therefore important to calculate the maximum junction temperature (T<sub>JMAX</sub>) for all applications to determine if power supply voltages, load conditions, or package type need to be modified to remain in the safe operating area. These parameters are related using Equation 1:

$$T_{JMAX} = T_{MAX} + (\theta_{JA} \times PD_{MAXTOTAL}) \tag{EQ. 1}$$

where:

- PD<sub>MAXTOTAL</sub> is the sum of the maximum power dissipation of each amplifier in the package (PD<sub>MAX</sub>)
- PD<sub>MAX</sub> for each amplifier can be calculated using Equation 2:

$$PD_{MAX} = 2 \times V_S \times I_{SMAX} + (V_S - V_{OUTMAX}) \times \frac{V_{OUTMAX}}{R_L} \tag{EQ. 2}$$

where:

- T<sub>MAX</sub> = Maximum ambient temperature
- θ<sub>JA</sub> = Thermal resistance of the package
- PD<sub>MAX</sub> = Maximum power dissipation of 1 amplifier
- V<sub>S</sub> = Supply voltage (Magnitude of V<sub>+</sub> and V<sub>-</sub>)
- I<sub>MAX</sub> = Maximum supply current of 1 amplifier
- V<sub>OUTMAX</sub> = Maximum output voltage swing of the application

R<sub>L</sub> = Load resistance

**ECG/EEG AMPLIFIER APPLICATION CIRCUIT**

ECG and EEG amplifiers must extract millivolt low frequency AC signals from the skin of the patient while rejecting AC common mode interference and static DC potentials created at the electrode-to-skin interface. In Figure 38, the EL8171 Instrumentation amplifier (U1) and the ISL28146 (U2) form a differential input, high impedance high pass patient lead amplifier. U2, RF1 and CF1 form a low pass active feedback amplifier. Inserting this amplifier in the feedback loop results in a high pass frequency response in the forward direction. The corner frequency is given by Equation 3:

$$f_{-HPF_{-3dB}} = 1/[2 \times \pi \times RF1 \times CF1] \tag{EQ. 3}$$

Voltage dividers R<sub>1</sub> through R<sub>2</sub> and R<sub>3</sub> through R<sub>4</sub> set the overall amplifier pass-band gain. Unwanted DC offsets appearing at the patient leads are cancelled by U2 at U1A's inverting input. Resistor divider pair, R<sub>3</sub> through R<sub>4</sub> define the maximum input DC level that is cancelled, and is given by Equation 4:

$$V_{INDC} = V + [R_4 / (R_3 + R_4)] \tag{EQ. 4}$$

In the passband range, U1B's gain is +1 and the total signal gain is defined by the divider ratios according to Equation 5:

$$V_{OUTU1Gain} = V_{OUT} / V_{IN} = [(R_1 + R_2) / R_2] \times [(R_3 + R_4) / R_4] \tag{EQ. 5}$$

The gain bandwidth product of the differential amplifier U1 determines the frequency response limit. Reference amplifiers U3A and U3B form a DC feedback loop that supplies a reference voltage drive to the patient to establish a common mode DC reference for the differential amplifiers. The voltage at the V<sub>CM</sub> sense electrode is maintained at the reference voltage set by RF1-RF2.

With the values shown in Figure 38, the performance parameters are:

1. Supply Voltage range = +2.4V to +5.5V
2. Total supply current draw @ +5V = 1.3mA (typ)
3. Common-mode reference voltage (V<sub>CM</sub>) = V+/2
4. Max DC Input Offset Voltage = V<sub>CM</sub> ±0.18V to ±0.41V
5. Passband Gain = 425V/V
6. Lower -3dB Frequency = 0.05Hz
