

## 1.0 Microprocessor Access

As seen on the microprocessor bus there are eight I/O addresses, selected by RS[2:0]. Two indirect schemes are used to access all of the internal registers and arrays through these eight primary I/O addresses.

The first scheme is standard VGA, and operates when RS[2] = 0. Of the four I/O addresses then available with RS[1:0], only one address directly accesses a register, the Pixel Mask. The other three addresses are used to indirectly access the three 256x8 palettes.

The second scheme is an indexed scheme and is used to access all of the remaining registers including the cursor array. This scheme operates when RS[2] = 1. Of the four I/O addresses then available using RS[1:0], two are used to load an index register (Low and High). The third address is used to write or read the register or array position pointed to by the index register. The fourth address is used to directly access a register which controls whether the index register automatically increments following an indexed register access.

The eight I/O addresses selected by RS[2:0] are listed in Table 1 below:

Table 1. I/O Addresses

RS[2:0]	Register
000	Palette Address (Write Mode)
001	Palette Data
010	Pixel Mask
011	Palette Address (Read Mode)
100	Index Low
101	Index High
110	Index Data (Indexed Registers)
111	Index Control

## 1.1 VGA Access

### 1.1.1 Palette

Internally the three 256x8 palettes are accessed by the microprocessor as a single 256x24 palette, with all 24 bits written or read in one operation.

A single Palette Address register points to 1 of 256 locations for writing or reading the 24 bits. Two different Register Select addresses are used to access the Palette Address register.

A write to RS[2:0] = 000 (Palette Address Write Mode) initializes the palette logic for write operations. Subsequent writes to Palette Data (RS[2:0] = 001) will load internal palette color registers and cause these register contents to be written into the palettes.

A write to RS[2:0] = 011 (Palette Address Read Mode) initializes the palette logic for read operations. Data from the palettes will be loaded into internal palette color registers. Subsequent reads from Palette Data (RS[2:0] = 001) will read these palette color registers.

Every three accesses of Palette Data (RS[2:0] = 001) will cause the Palette Address register to be incremented. An increment past 0xff will "wrap around" to 0x00.

A read from either Palette Address (Write Mode) or Palette Address (Read Mode) will read the Palette Address register. The same register is used for writing and reading, thus, changing modes destroys the contents of the previous mode's palette address. For example, if some reads are performed and then Palette Address (Write mode) is written, the read address will be lost and a read of either Palette Address (Write Mode) or Palette Address (Read Mode) will produce the same result: the address that was written into Palette Address (Write Mode).

### 1.1.2 Palette Write

Palette writes must be initialized by writing the Palette Address (Write Mode) register. This provides a starting address for writes and initializes the internal circuitry for palette write operations.

Palette writes are then performed by writing to Palette Data in a red, green, blue... sequence. These writes will load internal palette data registers in sequence. Immediately following every third write, an internal write will be triggered to the palette of the 24 bits contained in the internal palette data registers, at the address contained in the Palette Address register.

Immediately following the internal palette write triggered by the third write to Palette Data, the Palette Address register will be incremented. Thus, continuous writes to Palette Data will load the palette, stepping through the palette addresses in ascending order.

## 1.1.3 Palette Read

Palette reads must be initialized by writing the Palette Address (Read Mode) register. This provides a starting address for reads and initializes the internal circuitry for palette read operations.

Immediately following the writing of Palette Address (Read Mode), a read of the palette will be performed at the address just written. Internal palette data registers are loaded with the read data, and the Palette Address register is incremented.

Palette reads are then performed by reading from Palette Data. Red, green, blue... data from the preloaded internal registers will be presented in sequence. Immediately following every third read, an internal read of the palette to the 24 bits contained in the internal registers will be performed at the address contained in the Palette Address register.

Immediately following the internal palette read triggered by the third read of Palette Data, the Palette Address register will be incremented. Thus, continuous reads of Palette Data will read the palette, stepping through the palette addresses in ascending order.

## 1.1.4 6/8 Bit Palette Access

The original VGA had 6-bit DACs and 6-bit palette entries, and the low order 6 bits from/to the microprocessor port were written/read into the palette.

For RGB524, the DACs and palette entries are 8 bits. For non-VGA emulation all 8 bits are used. To emulate 6-bit VGA operation the upper 6 bits of the palette hold the VGA 6-bit color and the two low order bits are set to 00. The COL RES bit (color resolution) of the Miscellaneous Control 2 register determines if the access is 6-bit or 8-bit.

The reset condition is to emulate VGA using the 6 low order microprocessor data bits. COL RES is set to 6 bits. In this mode, for writing, microprocessor bits [7:6] are discarded, bits [5:0] are shifted to bits [7:2], and bits [1:0] are set to 00 before being written into the internal data registers. For reading, the internal data register bits [7:2] are shifted to bits [5:0], and bits [7:6] are set to 00 before being presented on the microprocessor data signals.

If COL RES is set to 8 bits then all 8 bits from/to the microprocessor will be written to and read from the color palette registers.

Note that the 6-to-8 bit translation is only done between the microprocessor port and the internal data registers. Internally, on writes, all 8 bits of the internal registers are written to the palette, and on reads, the internal registers retain all 8 bits read from the palette. Thus, if the palette is loaded with 8-bit values with COL RES set to 8 bits, and then the palette is read with COL RES set to 6 bits, the internal palette color registers will still be loaded with the 8 bits that were written into the palette. But the data read on the microprocessor data lines will be 6 bits.

## 1.1.5 Palette Clocking

Palette accesses are synchronized internally with the pixel clock. On writes, the pixel values of the previous cycle are held and displayed during the write cycle. Both of these features minimize disturbance of displayed pixels when the palette is accessed (anti-sparkle).

The pixel clock (as selected by the PCLK SEL bits in Miscellaneous Control 2) must be running for palette access to be valid.

The timings for the microprocessor signals are specified in units of pixel clocks. These specifications are derived from the requirement for the pixel clock to be running for palette access, as well as to allow time for the Palette Accesses and Palette Address increments to occur internally following a palette access.

## 1.1.6 Palette Access Status

The original VGA logic had an override for read accesses of the Palette Address (Read Mode) register. Instead of reading the Palette Address register, a value was returned that indicates the status of the last palette access, write or read.

The reset condition of RGB524 is to return the address value for a read of Palette Address (Read Mode). The VGA logic may be emulated by setting the RADR RFMT bit in Miscellaneous Control 1. This causes the status of the last palette access to be returned.

The value of the status returned is 0x00 if the last write to Palette Address was Write Mode, and 0x03 if the last write to Palette Address was Read Mode.

### 1.1.7 Pixel Mask

The pixel mask is an 8-bit register addressed with RS[2:0] = 010. It can be accessed at any time without disturbing a palette write or read sequence.

Accesses to the pixel mask are asynchronous to the pixel clock. Temporary color disturbances can be expected if the mask is changed while displaying pixels through the palette.

## 1.2 Indexed Access

The cursor array and a number of control registers are addressed with an internal 11-bit index register. The microprocessor accesses this as Index High (RS[2:0] = 101) and Index Low (RS[2:0] = 100).

A write or read to Index Data (RS[2:0] = 110) actually writes or reads the register/cursor array location addressed by the Index register.

Following a write or read of Index Data, the index register will increment if the INDX CNTL bit is set. The Index Control register (RS[2:0] = 111) contains this bit. To allow for future expansion, wraparound from 0x07ff to 0x0000 is **not** supported.

In general, access of Index Low, Index High, Index Control, or any of the Indexed registers is independent of the palette access and will not disturb a palette write or read sequence. However, as described above the PADR RFMT bit in Miscellaneous Control 1, the COL RES bit in Miscellaneous Control 2, and the 6BIT ACC bit in Palette Control all affect palette access.

Also, as described above, the pixel clock must be running for valid access of the palette, and the pixel clock is affected by a number of indexed registers.

### 1.2.1 Cursor Array

In general, the indexed registers may be written or read at any time, using the address held in Index High and Index Low. This address may be set by writing to Index High or Index Low, or the value may result from the auto-increment action of a previous access.

However, as described in section 5.2.3 Cursor Array Reads on page 19, to access the cursor array a write to Index High or Index Low must be performed first. That is, the cursor array cannot be accessed by auto-increment from address 0x00ff to 0x0100.

Also, as with the palette, the pixel clock must be running to access the cursor array.

## 2.0 Clocking

### 2.1 Clock Generators

There are two on-board clock generators: pixel clock and system clock (SYSCLK). Each clock generator uses a separate programmable phase locked loop (PLL).

The pixel clock generator provides the fundamental "dot" timings; it serves generally as the clock both for internal chip clocking and for on-card CRT timings.

The system clock generator is provided for the convenience of the graphics subsystem design. No internal use is made of this clock; the clock generator simply drives the SYSCLK output of the chip.

### 2.2 PLL Input

#### 2.2.1 REFCLK

The REFCLK input is a reference clock that the PLLs use in conjunction with programming registers to produce a wide variety of frequencies.

In general, REFCLK can be any frequency from 2 MHz through 100 MHz.

As discussed below, following a reset the PLL driving the SYSCLK output is enabled with the start-up frequency:

$$\text{SYSCLK frequency} = (33 / 16) \times \text{REFCLK frequency}$$

If it is important to have a particular frequency on SYSCLK following a reset, then the REFCLK frequency must be chosen that produces the desired SYSCLK frequency.

Also, when the "direct programming" method is used to program the PLL frequencies (see below), then REFCLK must lie on a 2 MHz boundary in the range of 4 MHz through 62 MHz (4 MHz, 6 MHz, 8 MHz, ... 62 MHz).

### 2.3 SYSCLK PLL Output

The system clock PLL drives the SYSCLK output. Two bits in the System Clock Control register affect this output. Bit 6, SYSC DSAB, is used to 3-state the driver. Bit 1, SYSC SRC, is used to bypass the SYSCLK PLL (the incoming REFCLK is steered to the SYSCLK output).

The supported frequency range for SYSCLK is 16.25 MHz to 100 MHz.

## 2.4 Pixel PLL Outputs

The pixel PLL is used internally as the pixel clock. The maximum allowed generated frequency is 170/220 MHz, dependent on the product version.

The pixel PLL Output is not available directly. However, two divided versions are provided as output signals:

- ❑ SCLK
- ❑ DDOTCLK

## 2.5 SCLK

SCLK (Serial Clock) is intended for clocking of the serial outputs of the VRAMs to the pixel port inputs. As such, the divide factor is a function of the VRAM pixel port width (64 or 32 bits), and the number of pixels contained in an access. For example, with a VRAM width of 64 and operating at 16 bits-per-pixel, there will be  $64/16 = 4$  pixels brought in with each VRAM access, and SCLK will operate at  $1/4$  the frequency of the pixel PLL output.

If the VGA port is selected SCLK will simply be the output of the pixel PLL. Table 2, "SCLK Frequencies," is a table of all the SCLK frequencies that are produced.

Table 2. SCLK Frequencies

BPP	VRAM=32	VRAM=64
4	$\div 8$	$\div 16$
8	$\div 4$	$\div 8$
15/16	$\div 2$	$\div 4$
32	$\div 1$	$\div 2$
24 Packed	Invalid	$\div (8/3)$
VGA	$\div 1$	

"24 Packed" is a special case. It is only valid with a VRAM width of 64, and it produces 3 SCLKs for every 8 internal pixel clocks as shown in Figure 1.

Figure 1. SCLK for 24 BPP Packed

The SCLK output can be inverted with the SCLK INVT bit of the Miscellaneous Clock Control register. This allows either polarity to be used, as desired, to aid in meeting critical timings at the card level.

The SCLK DSAB bit of the Miscellaneous Clock Control register can be used to 3-state the SCLK output if desired.

### 2.5.1 DDOTCLK

DDOTCLK (Divided Dot Clock) is simply the pixel PLL output divided by 1, 2, 4, 8 or 16 as determined by the DDOT DIV bits of the Miscellaneous Clock Control register.

Note that the maximum supported output frequency of DDOTCLK is 100 MHz, so some values of the DDOT DIV bits will become illegal when the pixel PLL is programmed to operate beyond this frequency.

When a pixel format of 24 BPP Packed is selected, the SCLK output may be driven on DDOTCLK instead of the divided pixel PLL output, under control of the B24P DDOT bit of the Miscellaneous Clock Control register.

DDOTCLK is similar to the SYSCLK output in that it is provided for general card use and is not used internally. However, its frequency is slaved to the pixel clock, whereas SYSCLK is independent. The DDOTCLK may be 3-stated with the DDOT DSAB bit of the Miscellaneous Clock Control register if desired.

**Note:** Although DDOTCLK and SCLK are both derived from the pixel clock, there is otherwise no particular relationship between the two clocks. In particular, the two clocks do not have any associated phase relationship.

## 2.6 Additional Clocks

### 2.6.1 Load Clock

The LCLK input (Load Clock) is used to latch up all incoming pixel data and video controls. The maximum frequency of this input is 100 MHz.

### 2.6.2 Pixel Clock (Dot Clock)

The pixel clock, or dot clock, is the internal clock used to clock pixel data up through the DACs. It is also required to be running to access the palette and the cursor. The maximum frequency of this clock is 170/220 MHz (depending on the chip version).

There are several sources of the pixel clock, as selected by the PCLK SEL bits in the Miscellaneous Control 2 register:

**LCLK input** This is the reset default. It is intended to be used when the VGA port is selected as the pixel source.

**Pixel PLL output** This is intended to be used when the VRAM pixel port is selected as the pixel source. It provides the highest pixel clock operation.

**REFCLK input** This is intended for laboratory bringup.

When LCLK is selected as the pixel clock all internal pixel operations are synchronous with LCLK. If the pixel clock is sourced by the pixel PLL output or REFCLK, then the incoming pixels and video controls are expected to be derived from SCLK. After latching the signals with LCLK, the signals are clocked with an internal SCLK, and then clocked with the internal pixel clock. LCLK must maintain a specified relationship to SCLK to achieve the internal transfer of the clocking from LCLK to SCLK.

## 2.7 PLL Setup and Reset

### 2.7.1 Pixel PLL

The PLL is enabled for running at a programmed frequency by setting the REF DIV COUNT, VCO DIV COUNT, and DF bits (as described in the following sections), and then setting the PLL ENAB bit of the Miscellaneous Clock Control register.

When the PLL ENAB bit is 0 (off), the PLL will continue to run but the frequency will not be determined by programming values. The PLL will drive to its lowest frequency of operation, in the range of 5 KHz to 250 KHz.

The pixel clock frequency is determined by the DF programming bits. When DF = 00, the pixel clock is equal to the PLL clock divided by 4 (1.25 KHz to 62.5 KHz). When DF = 01 the pixel clock equals the PLL clock divided by 2 (2.25 KHz to 125 KHz), and when DF = 10 or 11, the pixel clocks equals the PLL clock (5 KHz to 250 KHz.)

Following a reset, the PLL ENAB bit is off and the DF bits of all programming registers are set to 00, so the pixel clock will be PLL clock/4 = 1.25 KHz to 64.25 KHz.) The PORT SEL bit of Miscellaneous Control 2 register will be 0 (VGA port), which will cause the SCLK output to be the same as the pixel clock (1.25 KHz to 64.25 KHz.) The DDOT DIV bits of the Miscellaneous Clock Control register will be zero, which will cause DDOT-CLK to also be the same frequency as the pixel clock.

### 2.7.2 SYSCLK PLL

The SYSCLK PLL is enabled with the SPLL ENAB bit of the System Clock Control register. Unlike the pixel PLL, following a reset, this ENAB bit will be set, and the SYSCLK PLL will be running and driving the SYSCLK driver. The output frequency will be  $(33/16) \times \text{REFCLK}$ .

When the SPLL bit is 0 (disabled) the SYSCLK PLL will run in the 5 KHz to 250 KHz range similar to the pixel PLL. The frequency driven on the SYSCLK output will be determined by the value of the DF bits in the System PLL VCO Divider register, using the same divide factors as described above for the pixel PLL.

Table 3. PLL Equations

DF	Output Frequency	Internal VRF	Max Output Freq. (MHz)	
			170	220
00	$\frac{\text{FREF} \times (\text{VCO DIV COUNT} + 65)}{(\text{REF DIV COUNT}) \times 8}$	$\frac{\text{FREF}}{(\text{REF DIV COUNT}) \times 2}$	42.5	55.0
01	$\frac{\text{FREF} \times (\text{VCO DIV COUNT} + 65)}{(\text{REF DIV COUNT}) \times 4}$	$\frac{\text{FREF}}{(\text{REF DIV COUNT}) \times 2}$	85	110 (*)
10	$\frac{\text{FREF} \times (\text{VCO DIV COUNT} + 65)}{(\text{REF DIV COUNT}) \times 2}$	$\frac{\text{FREF}}{(\text{REF DIV COUNT}) \times 2}$	170 (*)	220 (*)
11	$\frac{\text{FREF} \times (\text{VCO DIV COUNT} + 65)}{\text{REF DIV COUNT}}$	$\frac{\text{FREF}}{\text{REF DIV COUNT}}$	170 (*)	220 (*)

1. FREF = REFCLK frequency
2. Frequencies marked with (\*) are maximum pixel PLL frequencies. The SYSCLK PLL maximum output frequency is 100 MHz.

## 2.8 PLL Programming

The two PLLs are programmed identically. Three values are used:

**REF DIV COUNT (Reference Divide Count)** This number provides a count value for dividing down the incoming REFCLK. It must be between 2 and 31. Operation of the PLL is indeterminate if this number is 0 or 1.

**VCO DIV COUNT (VCO Divide Count)** This number provides a count value for the divider in the PLL feedback loop. The value can range from 0 through 63. Internally, 65 is added to VCO DIV COUNT, so that the PLL feedback divider value ranges from 65 through 128.

**DF (Desired Frequency)** These are two bits with values of 00, 01, 10, and 11. The intent of these bits is to divide the operation of the PLL into four frequency ranges. Following the divide of the REFCLK provided by the REF DIV COUNT there is an additional divide-by-two which is selected or bypassed with the DF bits. Also, the output of the PLL has a divider stage, or postscaler, that is controlled by the DF bits.

Table 3, "PLL Equations," gives the general formulas for programming the PLLs. Because of the action of the DF bits there are four equations, one for each DF bit setting.

It is possible to program the PLLs with values that generate illegal operating conditions:

1. The reference frequency VRF (Video Reference Frequency), which is internal to the PLL, cannot be less than 1 MHz.
2. The internal VCO (Voltage Controlled Oscillator) cannot exceed the rated speed of the product (170/220 MHz).
3. The SYSCLK output driven by the SYSCLK PLL cannot exceed 100 MHz.
4. The DDOTCLK output driven by the pixel PLL cannot exceed 100 MHz.

Table 3, "PLL Equations," gives the equations for calculating the internal VRF. Table 3 also gives the maximum allowable output frequency for each setting of DF. This reflects the action of the VCO postscaler. If the PLLs are programmed so that these maximum dot clock frequencies are not exceeded then the maximum VCO frequency will not be exceeded.

## 2.9 PLL Frequency Selection

The REF DIV COUNT, VCO DIV COUNT, and DF bits are provided to the PLLs in a pair of 8-bit registers. REF DIV COUNT is 5 bits and occupies one register, with the 3 high order bits unused. The 6 VCO DIV COUNT bits occupy the second register, with the 2 high order bits used by DF.

For the SYSCLK PLL, the two programming registers are the System PLL Reference Frequency, which holds REF DIV COUNT, and the System PLL VCO Divider, which holds VCO DIV COUNT and the DF bits.

For the pixel PLL, there are actually 17 registers which can be used to hold the programming values: Fixed Pixel PLL Reference Divider and F0 - F15. A pair of registers is selected from this group to provide the pixel PLL programming values. This selection is controlled by the pixel PLL Control 1 and pixel PLL Control 2 registers.

Two different programming styles are supported:

**Direct Programming** In this scheme only the register holding VCO DIV COUNT and DF is altered to change the frequencies. The register for REF DIV COUNT holds a value that is constant for all frequencies. This method is discussed in more detail below.

**M over N** In this scheme both register values are changed to program a new frequency. The name refers to the general PLL concept in which

$$\text{Output frequency} = \text{Input reference} \times (M/N)$$

where VCO DIV COUNT serves as M and REF DIV COUNT serves as N, with modifications to the equation as shown in Table 3, "PLL Equations."

For the SYSCLK PLL there is not much distinction between the two programming styles. Both registers are written to provide an initial operating frequency. Then to change frequency either one register is changed (System PLL VCO Divider), or both registers are changed, depending on the programming style.

For the pixel PLL, a set of preprogrammed frequencies can be stored in the F0 - F15 registers, and the number of stored frequencies depends on the programming style.

When the direct programming style is used a single REF DIV COUNT is stored in the Fixed PLL Reference Divider register. Up to 16 values of VCO DIV COUNT and DF can be stored in the F0 - F15 registers, allowing 16 preprogrammed pixel clock frequencies.

With the M/N style the Fixed Pixel PLL Reference Divider register is not used. The F0 - F15 are reconfigured as 8 pairs of M and N values (M0,N0,M1,N1, ... M7,N7). This allows 8 preprogrammed pixel clock frequencies.

The selection of the programming registers, either 1 of the 16 F0 - F15 registers or 1 of the 8 M/N pairs, is done either externally with the FS[1:0] inputs to the module, or internally with the INT FS[3:0] bits of Pixel PLL Control 2 register. When the M/N style is used INT FS[3] is ignored.

The programming style and selection source is chosen with the EXT/INT bits of the Pixel PLL Control 1 register, as shown in Table 4, "Pixel PLL Control 1 EXT/INT Freq. Selection."

**Table 4. Pixel PLL Control 1 EXT/INT Freq. Selection**

EXT /INT	Frequency Selection	REF DIV COUNT	VCO DIV COUNT, DF
000	External FS[1:0]	Fixed Reference Divider	F0-F3
001	External FS[1:0]	N0-N3	M0-M3
010	Internal FS[3:0]	Fixed Reference Divider	F0-F15
011	Internal FS[2:0]	N0-N7	M0-M7

Note that there are more selections available with the internal register INT FS[3:0] than using the external FS[1:0] inputs. With the external inputs, only 4 frequencies can be chosen, using either direct programming or M/N. With the INT FS[3:0] bits 8 frequencies can be chosen using M/N or 16 frequencies can be chosen using direct programming.

Table 5. Direct Programming Reference Divider Values

REFCLK (MHz)	Fixed PLL Reference Divider Register Value
4	0x0002
6	0x0003
8	0x0004
10	0x0005
12	0x0006
14	0x0007
16	0x0008
18	0x0009

46	0x0017
48	0x0018
50	0x0019
52	0x001a
54	0x001b
56	0x001c
58	0x001d
60	0x001e
62	0x001f

## 2.10 Direct Programming

Use the following steps to calculate the values used with direct programming:

1. Look up the REFCLK frequency in Table 5, "Direct Programming Reference Divider Values," and write the given programming value into the PLL Reference Divider register (System PLL Reference Divider for the SYSCLK PLL, Fixed Pixel PLL Reference Divider for the pixel PLL). If the incoming REFCLK frequency does not appear in this table, then the direct programming method cannot be used.
2. Use Table 6, "PLL Direct Programming Equations," to determine the values to write into the VCO Divider register (System PLL VCO Divider for the SYSCLK PLL, F0 - F15 for the pixel PLL). First, pick the row of the table whose frequency range covers the frequency of interest. This will determine the value of the DF bits to write. Next, use the given equation to calculate the value of the VCO DIV BITS. Write these two values together to the appropriate register.

The generated pixel clock frequency is designated in this table as VF, for Video Frequency. Note that within each range the desired VF frequency must lie on a given step value (e.g., with DF = 11 a frequency of 159 MHz is invalid because it does not lie on a 2 MHz step; but either 158 MHz or 160 MHz is valid).

Table 6. PLL Direct Programming Equations

DF	VCO Divide Count	Frequency Range	Step (MHz)
00	$(4 \times VF) - 65$	16.25 - 32 MHz	0.25
01	$(2 \times VF) - 65$	32.5 - 64 MHz	0.5
10	$VF - 65$	65.0 - 128 MHz	1.0
11	$(VF / 2) - 65$	130.0 - 220 MHz	2.0

VF = Desired Video Frequency

## 2.11 M/N Programming

For the "M over N" programming style use Table 3, "PLL Equations," in the following steps:

1. Select values for REF DIV COUNT, VCO DIV COUNT, and DF that generate the desired frequency (or come close enough). Note that the values 0 and 1 are illegal for REF DIV COUNT under all conditions.
2. Calculate the internal reference frequency VRF. Verify that this frequency is not less than 1 MHz.
3. Verify that the dot clock frequency does not exceed the maximum value specified in the table.
4. If conditions 2 and 3 are not met then the selected values cannot be used.

## 2.12 General PLL Programming

Fundamentally the only differences between the two programming styles are these:

1. Direct programming can be used only if the REFCLK frequency falls on a 2 MHz boundary from 4 MHz through 62 MHz.
2. With direct programming, for a given pixel clock frequency there is only one set of programming values. These values are obtained from Table 5, "Direct Programming Reference Divider Values," and Table 6, "PLL Direct Programming Equations." Illegal conditions cannot be generated as long as the correct value from Table 5, "Direct Programming Reference Divider Values," is used.
3. M/N can be used with any REFCLK frequency from 2 MHz through 100 MHz.
4. A given pixel clock can be generated with multiple combinations of programming values. Some of these values can produce illegal internal conditions. Table 3, "PLL Equations," is used to calculate the resulting pixel clock and to determine if conditions are violated.

If the incoming REFCLK does not meet the requirements for direct programming, then M/N programming must be used for both PLLs.

If REFCLK is suitable for direct programming, then the programming style for the SYSCLK PLL is generally a matter of convenience.

For the pixel PLL, the use of preprogrammed frequencies, and the number required, 8 or 16, can affect the choice of programming styles.

However, the register selection specified with the EXT/INT bits of the Pixel PLL Control 1 register does not necessarily force the selection of programming style, direct or M/N. For example, there is nothing to prevent an arbitrary value from being written into the Fixed Pixel PLL Reference Divider and writing an appropriate value into one of the F0 - F15 registers as calculated with the M/N method. Of course, if multiple "N" values are used and they have to be re-written to the Fixed Pixel PLL Reference Divider every time the FS[3:0] value changes, this defeats the purpose of the FS[3:0] selection mechanism.

Likewise, when the 1-of-8 M/N register selection is used there is nothing to prevent using the direct programming equations from being used for the values. The same value will wind up being used for all of the "N" values.

## 2.13 PLL Interaction

The Pixel PLL and the SYSCLK PLL will interfere with each other (they will modulate the output frequency of the other PLL) if the higher frequency falls within 3 MHz of an integer multiple of the lower frequency. That is, if  $f_{\text{higher}}$  is the higher of the two frequencies and  $f_{\text{lower}}$  is the lower frequency, then the following equation must be satisfied:

$$f_{\text{higher}} \neq (n \times f_{\text{lower}}) \pm 3 \text{ MHz}; n = 1, 2, 3 \dots$$

## 2.14 Glitching on Frequency Change

When the operating frequency of either PLL is changed by changing one of the programming register values, the transition from the original frequency to the new frequency can either occur smoothly or can glitch, depending upon the following:

1. If the DF bits are not changed, then changing the REF DIV COUNT and VCO DIV COUNT bits will not cause a glitch.
2. If the DF bits are changed, then the PLL output can glitch.

## 2.15 Diagnostic Readback

The read-only registers Pixel PLL VCO Divider Input and Pixel PLL Reference Divider Input contain the programming values actually used by the pixel PLL. These registers can be used to verify that the desired programming registers are the ones actually selected.

### 3.0 Modes of Operation

Pixel data can come from the VGA port or the VRAM pixel port, as selected by the PORT SEL bit of the Miscellaneous Control 2 register.

If the VRAM pixel port is selected, the pixel format can be 4 BPP (bits per pixel), 8 BPP, 15/16 BPP, 24 BPP Packed, or 32 BPP, selected by the Format bits of the Pixel Format register. Table 7, "Pixel Format Table," on page 15 shows how the input bits are selected as a function of Pixel Format.

VGA data and 4 BPP data are always used to indirectly generate 24 bits of color by indexing into the 256 entry palettes. The Pixel Mask register is used to selectively mask off the index bits as desired.

8 BPP, 15/16 BPP, 24 BPP Packed, and 32 BPP from the VRAM pixel port can either be indirect (through the palettes) or direct (bypassing the palettes).

Each of these formats has an associated control register with bits to select indirect or direct color. Additionally 15/16 BPP and 32 BPP formats allow a bit within the incoming data to dynamically select indirect or direct color.

As with VGA and 4 BPP, the Pixel Mask is used to mask off palette address bits with indirect color access for 8, 15/16, 24 Packed, and 32 BPP.

### 3.1 Bit Ordering

Bit order is high-to-low. For 8 BPP, the MSB is '7' and the LSB is '0'; for 16 BPP the MSB is '15' and the LSB is '0', and so on.

When the VRAM pixel port is selected the default condition is to access the pixels from low to high. For each LCLK, the first pixel used is at the end with bit PIX[00], and the last pixel used is at the end with bit PIX[63] (bit PIX[31] for VRAM width = 32). For example, for 8 BPP, the first pixel is PIX[07:00], the second pixel is PIX[15:08], and so on.

4 BPP is a special case. Within a byte, the default condition is to select first the high nibble (e.g., PIX[07:04]), then the low nibble (PIX[03:00]). The SWAP NIB bit of the Miscellaneous Control 3 register may be used to swap the order the two nibbles are used. This swap is applied to every byte that is read in, and is only active, when set, for 4 BPP.

### 3.2 VGA Port

VGA uses 8 bits per pixel. When the VGA port is selected only indirect mode is used. The 8 bits are masked with the Pixel Mask register and presented to the red, green, and blue palettes as indices into the 256 entries of each palette. The masked data is used as the same index into each of the three color palettes.

### 3.3 VRAM Pixel Port

#### 3.3.1 4 BPP

With 4 BPP format 8 pixels (32 bit VRAM width) or 16 pixels (64 bit VRAM width) are obtained for each pixel port data access. As noted above the default access of the two pixels within each byte are high-to-low:

PIX[7:4] = pixel one

PIX[3:0] = pixel two,

but this can be reversed with the SWAP NIB bit of the Miscellaneous Control 3 register.

4 BPP is only used in indirect color mode. The 4 bits are masked with the 4 low order bits [3:0] of the Pixel Mask. The resultant masked 4 bits are then used to index into each of the red, green, and blue palettes.

With 4 BPP the 256 entry palettes are divided into 16 partitions of 16 entries per partition. The upper 4 bits of the Pixel Mask register are ignored. The PARTITION bits of the Palette Control register are used as the upper 4 bits of the palette address to select the desired partition. The 4 masked pixel bits are used to index to 1-of-16 entries within the selected partition.

### 3.3.2 8 BPP

With 8 BPP format 4 pixels (32 bit VRAM width) or 8 pixels (64 bit VRAM width) are obtained for each pixel port data access.

8 BPP can be indirect or direct, under control of the B8 DCOL bit of the 8 BPP Control register. If indirect, the 8 bits are masked with the Pixel Mask register and presented to the red, green, and blue palettes as indices into the 256 entries of each palette.

If direct, the 8 bits are presented to the red, green, and blue DACs. Note that since the red, green, and blue colors are identical the displayed image will be monochrome.

### 3.3.3 16 BPP

With 15 BPP or 16 BPP format 2 pixels (32-bit VRAM width) or 4 pixels (64-bit VRAM width) are obtained for each pixel port data access. The 15 or 16 bits are expanded to 24 bits, under control of the 16 BPP Control register.

The 16 BPP Control register provides a number of options for using the 16 BPP format:

1. The incoming pixel can be 15 bits (555 format) or 16 bits (565 format).
2. The color path can be indirect (through the palettes) or direct (bypassing the palettes). Also, with 555 format, the 16th bit can be used to dynamically switch on a pixel-by-pixel basis between indirect and direct color.
3. If indirect color is selected, the addressing of the palettes can be "sparse" (pixel bits used as high order palette address bits) or "contiguous" (pixel bits used as low order palette address bits).
4. If indirect color with contiguous addressing is selected, the palettes can be divided into partitions. The PARTITION bits of the Palette Control register are used to select the partition by filling in the upper palette address bits. With 555 format 8 partitions are available; with 565 format there are 4 partitions.
5. If direct color is used the pixel bits are sent to the DAC high order bits. The low order bits can be zero filled, or the low order bits can be filled with the high order bits of the pixel data. (See description of ZIB/LIN bit below.)

If dynamic bypass is selected the following conditions will apply:

1. The format will be forced to 15 bit (555), with the unused 16th bit now used to control indirect/direct color selection.
2. The indirect color path will be forced to use sparse addressing of the palettes. Partitions cannot be used.
3. The direct color path will force the low order bits to the DACs to be zero filled (ZIB). LIN format cannot be used.
4. The Pixel Mask will mask the pixel data regardless of whether or not the palette is bypassed.

#### 3.3.3.1 555/565 Formats

The 555/565 bit determines if the pixel is 15 bits (5:5:5 format) or 16 bits (5:6:5 format). The format designator, 5:5:5 or 5:6:5, refer to the bit allocations, high-to-low, for red:green:blue.

With 15 BPP the high order bit of each two bytes (PIX[15], PIX[31], PIX[47], PIX[63]) is discarded unless dynamic bypass is specified (B16 DCOL bits = 01). With dynamic bypass, this bit is used for indirect/direct color selection.

As noted above setting the mode to dynamic bypass will force the format to 555 regardless of the setting of the 555/565 bit.

#### 3.3.3.2 Color Path Selection

The B16 DCOL bits are used to select one of:

1. Indirect color always (00).
2. Direct color always (11).
3. Dynamic selection of indirect or direct color (01).

The expansion to 24 bits varies depending on whether the color path is indirect or direct.

**Indirect Color:** The palette addressing can be sparse or contiguous and is controlled by the SPR/CNT bit. With sparse addressing the pixels will address 32 locations each for the red and blue palettes, and 32 locations for green in 555 format or 64 locations for green in 565 format. With the lower address bits set to zeroes the locations accessed will be "scattered" through the palettes, with the intermediate locations unused.

With contiguous addressing the PARTITION bits of the Palette Control register are used for the high order palette address bits, and the access within each palette is

contiguous. For 555 format there are 8 partitions and 32 entries within each partition. For 565 format there are 4 partitions. All 64 entries in the green palette are addressed. Only the lower 32 entries of the red and blue palettes are used; the high 32 entries are not used.

For sparse addressing the low order bits are dependent on the ZIB/LIN bit. This bit *must* be set to 0 (ZIB). This will force the low order bits to zeros. If ZIB/LIN is 1 (LIN) then the values of the low order bits presented to the palettes are undefined.

For sparse addressing the low order Pixel Mask bits have no effect.

For contiguous addressing the high order bits are always supplied by the PARTITION bits and the high order Pixel Mask bits have no effect.

As noted above for dynamic bypass mode the format is forced to 555 mode and addressing is forced to be sparse regardless of the setting of the SPR/CNT bit.

**Direct Color:** To expand the 5 or 6 bits of color from the pixel data to 8 bits, the ZIB/LIN bit of the 16 BPP Control register specifies the generation of the low order 3 or 2 bits. If ZIB (Zero Intensity Black), the low order bits are made 0. If LIN (Linear), the low order bits are made equal to the high order bits. This causes the 5 or 6 bits to expand to 8 bits in a linear fashion, with both zero scale and full scale values used. With Zero Intensity Black, full scale cannot be achieved.

As noted above for dynamic bypass mode the format is forced to 555 mode and the low order fill is forced as ZIB, regardless of the setting of the ZIB/LIN bit.

### 3.3.3.3 Dynamic Bypass

As described above the selection of "dynamic bypass" mode forces the 555 format and uses the high order bit of the incoming 16-bit pixels as a control bit to select, on a pixel-by-pixel basis, the indirect (color lookup) or direct (lookup bypass) path.

The meaning of this bit depends on the BY16 bit in the 16 BPP Control register. When BY16 = 0 the incoming control bit forces the bypass. That is, when the control bit is 1 the palette is bypassed (direct color), and when 0 the palette is not bypassed (indirect color).

When BY16 = 1 the meaning of the incoming control bit is reversed; it now forces a lookup. That is, when the control bit is 1 the palette is used (color lookup), but when 0 the palette is bypassed (direct color).

### 3.3.4 24 BPP

24 BPP Packed can only be selected when the VRAM width is 64 bits. If 24 BPP Packed format is selected with the Pixel Format register, but the VRAM SIZE bit in the Miscellaneous Control 1 register is set for 32 bits, then the product operation is undefined.

With 24 BPP Packed format each 64-bit pixel port data access contains  $2\frac{2}{3}$  pixels. Every 3 consecutive pixel port data accesses ( $3 \times 8 = 24$  bytes) contains 8 pixels of 3 bytes each. The assignment of the bytes for each of the three accesses is shown in Figure 2 on page 12. Each byte contains 8 bits of red, green, or blue color. Color access can be indirect or direct, and is selected with the B24P DCOL bit of the 24 BPP Packed Control register.

For indirect color, the 8 bits of red, green, and blue are each masked by the Pixel mask, and then presented to the red, green, and blue palettes as indices into the 256 entries of each palette.

For direct color, the 8 bits of red, green, and blue are presented to the DACs.

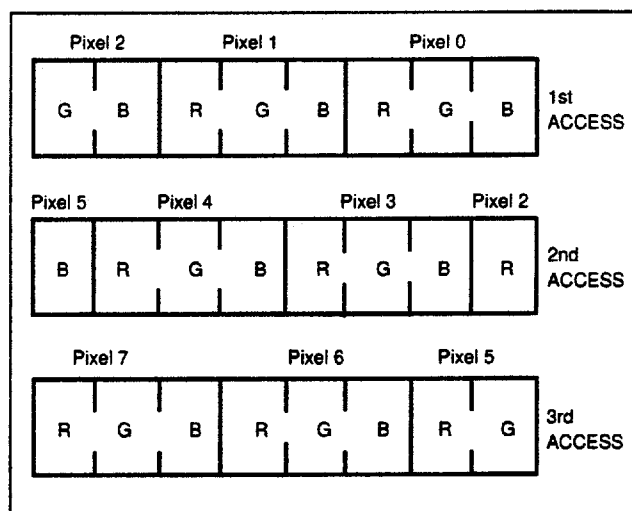

Figure 2. 24 BPP Packed Pixel Input from VRAM

### 3.3.5 32 BPP

With 32 BPP format 1 pixel (32-bit VRAM width) or 2 pixels (64-bit VRAM width) are obtained for each pixel port data access. For each 32 bits accessed, the low three bytes (24 bits) are used for the three colors, with 8 bits each for red, green, and blue.

32 BPP mode is controlled with the 32 BPP Control register. This register has the B32 DCOL bits, which are used to select one of:

1. Indirect color always (00).
2. Direct color always (11).
3. Dynamic selection of indirect or direct color (01).

With indirect color always or direct color always the high order byte is unused. (PIX[31:24] and PIX[63:56])

With dynamic selection (dynamic bypass), the "25th" bit is used as the indirect/direct control bit (PIX[24], PIX[56]) and the remaining bits of the high order byte are unused. (PIX[31:25] and PIX[63:57].) The pixel data in this mode is masked by the Pixel Mask regardless of whether or not the palette is bypassed.

For indirect color, the 8 bits of red, green, and blue are each masked by the Pixel mask, and then presented to the red, green, and blue palettes as indices into the 256 entries of each palette.

For direct color, the 8 bits of red, green, and blue are presented to the DACs.

#### 3.3.5.1 Dynamic Bypass

As described above the selection of "dynamic bypass" mode uses the "25th" bit of the incoming 32-bit pixels as a control bit to select, on a pixel-by-pixel basis, the indirect (color lookup) or direct (lookup bypass) path.

The meaning of this bit depends on the BY32 bit in the 32 BPP Control register. When BY32 = 0 the incoming control bit forces the bypass. That is, when the control bit is 1 the palette is bypassed (direct color), and when 0 the palette is not bypassed (indirect color).

When BY32 = 1 the meaning of the incoming control bit is reversed; it now forces a lookup. That is, when the control bit is 1 the palette is used (color lookup), but when 0 the palette is bypassed (direct color).

### 3.4 6 Bit Linear Palette Output

The 6BIT LIN (6 bit linear) bit of the Palette Control register affects the format of the color data read from the palettes and presented to the DACs in indirect color mode. It only has effect when the color resolution is set to 6 bits with the COL RES bit of the Miscellaneous Control 2 register and DCOL CNTL is set to indirect color.

If the palettes contain data with the two low order bits set to 00 (which will be the case when the palettes are loaded with COL RES set to 6 bits), without special processing the data values presented to the DACs will range from 0x00 through 0xfd. The maximum output of the DACs will be approximately 1.5% less than full scale (0xff). This will occur when 6BIT LIN is set to 1.

When 6BIT LIN is set to 0 (the default), then the outputs of the palettes will be modified to allow the DACs to reach full scale output. The modification consists of discarding the two low order bits from the palettes, and substituting the two high order bits for the two low order bits presented to the DACs. (i.e., the palette bits presented to a DAC will be bits 7 6 5 4 3 2 7 6).

With this bit substitution there will be a "linear" mapping of the palette data range (0x00 – 0xfd) to the DAC data range (0x00 – 0xff), and the DACs will operate over their full range.

If COL RES = 1 (8-bit color resolution) the palette outputs are presented to the DACs unchanged, and 6BIT LIN has no effect. The DACs will operate over the 8-bit range from completely off to full scale on.

Palette linear output is intended for emulation of the VGA 6-bit DACs in which the palette is loaded with 6-bit colors in the 6 high-order bits by setting COL RES to 6-bits. However, regardless of how the palette was loaded or what the pixel format is (VGA, 4, 8, 15/16, 24, 32 BPP), if enabled (DCOL = indirect, COL RES = 6 bit, 6BIT LIN = 0) the palette outputs will be affected as discussed above.

In summary, with the default conditions for VGA mode (indirect color, 6-bit color resolution, 6BIT LIN = 0), there will be a linear mapping of the 6-bit VGA palette data to the DACs, and the DACs will operate over their full range. The mapping can be turned off by setting 6BIT LIN to 1, in which case the 8 bits from the palettes are presented to the DACs unmodified. With 00 in the two low order bits of the palettes the DACs will not reach full scale output.

With 8-bit color resolution (indirect color), or with direct color, the setting of 6BIT LIN has no effect.

## 3.5 Pixel Format Table

Table 7 shows the bit assignments of the pixel data port for each supported pixel format. Prefixes A - P identify individual pixels, and numbers 0 - 7 identify the bit within the pixel. For 4 bit pixels, this information is the data seen by the three color palettes. For 8 bit pixels, it is the data seen by the three color palettes in indirect color mode, and it is the data seen by the three DACs in direct color mode. The suffixes (blu, grn, red) identify the data seen by each of the color palettes (indirect mode) or each of the DACs (direct mode) for 16, 24, and 32 bit pixels.

Table 7. Pixel Format Table

Note 1: In 4 BPP mode the 4 most significant bits of each pixel come from the partition bits of the palette control register.

Note 2: For 15/16 BPP Direct Color the low order bits for each color component are determined by the ZIB/LIN Bit of the 16 BPP Control register. For 15/16 BPP sparse format (indirect color), the ZIB/LIN bit must be set to ZIB, and the low order bits for each color component will be zeroes.

Note 3: In CONTIGUOUS format for 15/16 BPP the most significant bits of each pixel come from the partition bits of the palette control register.

Note 4: These bits are used for DYNAMIC BYPASS when that mode is enabled, otherwise they are unused.

## 4.0 Controls

### 4.1 Blank and Border Control

The **BLANK** and **BORDER/OE** signals control the way in which data is presented to the DACs. These control signals are used to determine when pixel data is valid, when the border color is to be displayed, where the cursor should be located on the screen, and how the MISR will accumulate its signature.

### 4.2 Blanking Control

**BLANK** is latched by the rising edge of LCLK. When **BLANK** is active (low), the data presented to the DACs is forced to zeroes. When **BLANK** is inactive (high), the pixel data or VGA data is considered valid (unless **BORDER** is active), and the data is presented to the DACs as determined by the current mode of operation. Cursor data will override pixel data when the cursor is to be displayed.

### 4.3 Vertical Blanking

When **BLANK** is active (low) an internal counter is used to determine whether or not the current blanking interval is vertical blanking. If the counter reaches its maximum count of 2048 pixels, an internal signal will become active to indicate that the end of the current frame has been reached. This internal signal will remain active until **BLANK** becomes inactive (high). This vertical blanking detection is used by the cursor logic to position the cursor (if enabled) in the following frame. It is also used by the MISR (if enabled) to control the accumulation of a signature for one complete frame of pixel data.

### 4.4 Border Control

**BORDER/OE** is a shared function input. It can indicate either "Border" time, for displaying a border, or "Odd/Even" for use with interlace mode. The usage of this pin is determined by the BRDR/INTL of the Miscellaneous Control 2 register. When used as a border control interlace mode is not supported with display of the hardware cursor.

When used as **BORDER**, the input is latched by the rising edge of LCLK. When **BLANK** is active (low), **BORDER** must also be active (low). When **BLANK** is inactive (high), the state of **BORDER** will determine whether or not the color in the Border Color registers is displayed.

If **BORDER** is active (low), the border color is displayed, and if **BORDER** is inactive (high), the pixel data or cursor data is displayed. For cursor positioning, the active display area is considered valid when **BORDER** and **BLANK** are both inactive (high). The MISR signature is accumulated when **BLANK** alone is inactive (high), thus the border area is included in the MISR accumulation. If no border is required, the **BORDER** input should be tied to **BLANK**.

The intent of the **BORDER** signal is to create a "picture frame" around the active display area. **BORDER** can remain active (low) for entire scan lines at the top and bottom of the active display area, or it can be active at the beginning and end of each scan line to create this effect. Other changes in the **BORDER** signal within the active display area are not allowed.

If the BRDR/INTL bit in Miscellaneous Control 2 is set to "INTL" operation, no border will be displayed.

### 4.5 Sync Control

Three sync signals are brought into the device on two pins, **HCSYNCIN** and **VSNCIN**.

Four registers control what is done with these signals:

- ☐ Sync Control (index 0x0003)
- ☐ Horizontal Sync Position (index 0x0004)
- ☐ DAC Operation (index 0x0006)
- ☐ Power Management (index 0x0005)

Horizontal sync on **HCSYNCIN** is processed and sent out on **HSYNCOUT**. Vertical sync on **VSNCIN** is processed and sent out on **VSNCOUT**.

The intent of processing horizontal sync is to delay it to match the delay seen by the pixel data from the inputs (VGA[7:0] or PIX[63:0]) to the DAC outputs. In addition, the signal may be inverted, forced low or high, or 3-stated.

A mismatch between pixel delay and horizontal sync delay can cause a visible effect, that is, the display may not be centered horizontally on the screen. The vertical display timings are generally such that mismatches are not visible. Vertical sync is brought in on **VSNCIN** and sent out on **VSNCOUT** to provide the same invert, force low or high, and 3-state controls as provided for horizontal sync.

Composite sync on HCSYNCIN may be injected onto the Green DAC output for composite-sync-on-green. This function is enabled by setting the SOG bit of the DAC Operation register. If this bit is off HCSYNCIN is not used for composite sync.

The composite sync is delayed internally to match the pixel pipeline delay.

Since horizontal and composite sync are shared, only one of them should be enabled at a given time. For example, if the signal on HCSYNCIN is horizontal sync, then the SOG bit on the DAC control register should be off. Or, if SOG is on to inject composite sync on HCSYNCIN onto the green DAC output, some decision must be made on how to handle the HSYNCOUT output (force low, high, 3-state, or leave unconnected).

## 4.6 Clocking and Pipeline Delay

### 4.6.1 Horizontal Sync

The clocking and delay of HCSYNCIN to HSYNCOUT depends on the DLY CNTL bit of the Sync Control register. If this bit is set to 1, HCSYNCIN is passed directly to HSYNCOUT without latching and without pipeline delay matching.

If DLY CNTL is set to 0 and SOG is off (no composite sync), then HCSYNCIN is latched on the rising edge of LCLK and delayed internally to match the pixel pipeline delay before being sent out on HSYNCOUT. Also, additional delay may be added with the Horizontal Position register (see section below).

If SOG is on (composite sync) then DLY CNTL has no effect and HCSYNCIN is passed directly to HSYNCOUT without latching and without pipeline delay matching. (This is not a typical use for this input, it is just a byproduct of sharing horizontal sync with composite sync.)

### 4.6.2 Vertical Sync

VSYNIN is passed directly to VSYNOUT without latching and without pipeline delay matching.

### 4.6.3 Composite Sync

The HCSYNCIN input is always latched on the rising edge of LCLK for use as composite sync. When enabled with the SOG bit, it is delayed internally to match the pipeline delay of the pixel data, and then is injected onto the Green DAC output. As with horizontal sync, additional delay can be added with the Horizontal Sync Position register.

### 4.6.4 Horizontal Position Control

Additional delay of 0 to 15 pixel clock periods may be added to the horizontal sync and composite sync signals with the Horizontal Sync Position register.

The intent of this additional delay is to provide a "fine tune" control of the horizontal screen position. Typically the incoming sync signals can only be adjusted in multiples of the pixel clock. The additional delay added with the Horizontal Position Control register adjusts the screen position with pixel increments.

The Horizontal Position register can be used on horizontal sync when DLY CNTL is set to 0 and SOG is off. The register can be used with composite sync when SOG is on.

## 4.7 Additional Sync Control

The polarity of the received HCSYNCIN input may be inverted before it is applied to the green DAC using the CSYN INVT bit of the Sync Control register.

The polarity may be inverted between HCSYNCIN and HSYNCOUT using the HSYN INVT bit, and the polarity may be inverted between VSYNIN and VSYNOUT using the VSYN INVT bit.

The HSYNCOUT and VSYNOUT signals may be individually forced low, forced high, or forced to high impedance using the HSYN CNTL and VSYN CNTL bits of the Sync Control register.

As discussed in 7.3 "Clocking Power" on page 22, the clocks to the sync delay circuits can be shut off with the SYNC PWR bit of the Power Management register.

## 4.8 24 Bit Packed Pixel Control

The 24 bit packed pixel format requires special consideration. In this mode the pixel data at the beginning of a line must be aligned on an eight pixel boundary as shown in Figure 2, "24 BPP Packed Pixel Input from VRAM" on page 12. These eight pixels correspond to three 64-bit pixel port loads or three SCLK cycles. In order to keep pixel data and control signals properly aligned, all control signals (BLANK, BORDER/OE and HCSYNCIN) are required to change in increments of eight pixels (3 SCLKS). When either BLANK or BORDER/OE changes to indicate the beginning of an active display line, it is assumed that the pixel data which begins that line is aligned on the proper eight pixel boundary.

## 5.0 Cursor Operation

The cursor is a 32x32 or 64x64 pixel pattern that is overlaid on the display pixels just before presentation to the DACs. The cursor size, 32x32 or 64x64 is set with the CURS SIZE bit of the Cursor Control register.

Pixel columns are numbered left to right starting with 0. Pixel rows are numbered top to bottom starting with 0.

### 5.1 Cursor Enable

The cursor is enabled when the CURSOR MODE bits of the Cursor Control register are not 00. When enabled, the cursor will display if it has not been moved off-screen. If disabled (CURSOR MODE = 00), the cursor will not be displayed.

The cursor may be used with either pixel port (VGA or PIX), with any of the pixel formats (VGA, 4, 8, 15/16, 24, 32 BPP), and with indirect or direct color.

## 5.2 Cursor Array

The cursor image is stored in the Cursor Array. The array is organized 1024x8 (1024 bytes). It is accessed as Indexed Data using index addresses 0x0100 through 0x04ff.

Each pixel of the cursor uses 2 bits, thus 4 cursor pixels are stored in each byte of the array. The entire array is used to contain the 64x64 cursor image (4 pixels/byte × 1024 bytes = 4096 pixels = 64x64).

For the 32x32 cursor only 256 bytes are required (4 pixels/byte × 256 bytes = 1024 pixels = 32x32.) The cursor array is divided into four contiguous slots to allow the storage of four cursor images. The SMLC SLOT bits of the Cursor Control register are used to select one of the four slots for display. The SMLC SLOT bits have no effect when the cursor size is 64x64.

Storage of the cursor within the array starts with the top row. For the 64x64 cursor the first 16 bytes hold row 0, the next 16 bytes hold row 1, and so on, starting with the first byte in the array at index address 0x0100.

For the 32x32 cursor the first 8 bytes hold row 0, the next 8 bytes hold row 1, and so on, starting with the first byte in a slot (index addresses 0x0100, 0x0200, 0x0300 or 0x0400).

Within a row the pixels are stored left to right in groups of four. The first byte holds pixels 0, 1, 2, 3, the next byte holds pixels 4, 5, 6, 7, and so on.

Within a byte the four pixels may be stored right to left or left to right, depending on the PIX ORDR bit of the Cursor Control register. If PIX ORDR = 0 the pixels are stored right to left (3, 2, 1, 0); if PIX ORDR = 1 the pixels are stored left to right (0, 1, 2, 3).

### 5.2.1 Cursor Array Access

Cursor Array writes and reads are synchronized with the internal pixel clock, so the pixel clock must be running for microprocessor accesses to be valid. If this condition is met, the cursor array may be written or read at any time.

Microprocessor read accesses of the cursor array may disturb the cursor image if it is being displayed at that time. However, no more than one cursor pixel will be disturbed per cursor read access. Microprocessor write accesses of the cursor array will not disturb the cursor.

### 5.2.2 Cursor Array Writes

A write to the cursor array is accomplished by writing the Index High and Index Low registers with an index address for the array (0x0100 – 0x04ff), followed by a write of the desired data to Index Data. If auto-increment is turned on, the entire array may be written sequentially by repeated writes to Index Data.

### 5.2.3 Cursor Array Reads

To meet the bus timings for reads, the cursor array read data is pre-fetched. A pre-fetch is triggered by writing the Index High or Index Low register such that the resulting index address is for an entry in the array (0x0100 – 0x04ff). At the end of the write cycle the cursor array will be read at the address held in the index address registers, and the read data will be held in an internal register. A subsequent read of Index Data will read this pre-fetched data. At the end of the read another pre-fetch will be triggered. If auto-increment is turned on, this pre-fetch will be for the next address in the array. Thus, the entire array can be read by repeated reads from Index Data.

The pre-fetching of cursor array data will stop if

1. The index register auto-increments beyond 0x04ff  
OR
2. A write is done to Index Data

### 5.3 Cursor Modes

Each pixel of the cursor is specified with 2 bits. There are three ways that these 2 bits can be used, as specified by the CURSOR MODE bits of the Cursor Control register. These are shown in Table 8, "Cursor Modes," on page 21.

There are three cursor colors that may be displayed. The colors are stored in the Cursor Color 1 Red, Green, Blue, Cursor Color 2 Red, Green, Blue, and Cursor Color 3 Red, Green, Blue registers. Each red, green, and blue register is 8 bits, yielding a full 24-bit color for each of the three cursor colors. The cursor color is always 24 bits, and is not affected by the COL RES or 6BIT LIN control bits, or any of the pixel formats (VGA, 4, 8, 15/16, 24, 32 BPP).

Cursor Mode 0 allows selection of any of the three colors while Modes 1 and 2 allow selection between colors 1 and 2.

All modes can specify that the cursor pixel be transparent, to allow the underlying display pixel to be displayed. This pixel will either be a palette output or a formatted VRAM pixel, depending on whether the pixel format is VGA or indirect color, or direct color.

Mode 1 can also specify that the complement of the underlying display pixel be displayed. The intent is to highlight the cursor by "reversing" the color of the background pixels.

### 5.4 Cursor Hot Spot

The hot spot is the point within the cursor that is used to locate the cursor's position on the screen. Any pixel within the cursor may be identified as the hot spot.

The Cursor Hot Spot X and Cursor Hot Spot Y registers hold the unsigned cursor pixel X (column) and Y (row) coordinates for the hot spot. The range for the X and Y values is 0 to 31 for the 32x32 cursor and 0 to 63 for the 64x64 cursor.

## 5.5 Cursor Position

The Cursor X Low, Cursor X High, Cursor Y Low, and Cursor Y High registers specify the position of the cursor (the cursor hot spot) on the screen.

The X and Y positions are specified as *signed* numbers in two's complement format. The High and Low pairs yield 16-bit position registers, of which 12 bits plus a sign bit are used.

The hardware automatically extends the sign bit into the unused bit positions of the position registers. The valid X and Y ranges are -4096 to +4095.

The X and Y screen coordinates are for non-border display pixels. (0,0) is the upper left corner pixel of the screen that is not in the border area. The X value increases positively left-to-right, and the Y value increases positively top-to-bottom. Negative X values are to the left of the non-border display area and negative Y values are above the top of the non-border display area.

The cursor is clipped by the edges of the screen if there is no border, or by the border if a border is used. For example, if the hot spot is (0,0) the full cursor will be displayed in the upper left corner if the X position is +0 and the Y position is +0. If the X value is changed to -1 (0xffff) only columns 1 through 31 of the cursor will be displayed. If the X value is -31 (0xffe1) only column 31 of the cursor will be displayed. If the X value is more negative than -31 the cursor will not be displayed.

## 5.6 Interlace

The selection of cursor rows for display is changed if interlace mode is specified. This is controlled with the INTL MODE bit of the Miscellaneous Control 2 register.

In non-interlaced mode, the cursor rows are displayed sequentially, starting with the first non-clipped row to be displayed based on the Y position and Y Hot Spot register contents.

When interlaced mode is specified, the ODD/EVEN signal (actually BORDER/OE, see below) is used to determine if odd or even scan lines are being displayed. If ODD/EVEN is low (even field), the first non-clipped cursor row that falls on an even scan line is displayed. Similarly if ODD/EVEN is high (odd field), the first non-clipped cursor row that falls on an odd scan line is displayed. In either case, if the first cursor line displayed is an even-numbered cursor row (as determined by Y Position and Y Hot Spot) then successive even-numbered

cursor rows will be displayed during that field. If the first cursor line displayed is an odd-numbered cursor row then successive odd-numbered cursor rows will be displayed during that field.

ODD/EVEN should only change during vertical blanking time for proper cursor display.

The ODD/EVEN input is actually the shared input pin BORDER/OE, where the usage of the pin is determined by the BRDR/INTL of the Miscellaneous Control 2 register. BRDR/INTL must be set to INTL for using the cursor with interlaced mode. If BRDR/INT is set as BRDR then the INTL MODE bit will be ignored (non-interlaced mode will be used).

## 5.7 Cursor Update and Display

### 5.7.1 Position

Writing any of the Cursor X Low, Cursor X High, or Cursor Y Low registers will not affect the position of the cursor on the screen. When the Cursor Y High register is written, the X and Y positions are captured in a second set of registers.

When vertical blanking is detected (see 4.3 "Vertical Blanking" on page 16), the "captured" X and Y positions are sampled. The sampled position is saved until it is re-sampled on the next vertical blanking time. Between vertical blanking times the sampled position is used, along with the Cursor Hot Spot, to calculate which pixels of the cursor are used and where they are displayed on the screen.

When INTL MODE is set the ODD/EVEN signal is examined at the end of vertical blanking to determine if only even or only odd rows will be displayed.

### 5.7.2 Controls

When vertical blanking is detected the Cursor Control register is sampled along with the X and Y position registers. This allows the cursor to be toggled on and off on a frame-by-frame basis with the CURSOR MODE bits, and if the cursor is 32x32, it allows toggling among the four slots on a frame-by-frame basis using the SMLC SLOT bits.

Note that in interlace mode the sampling is on a field-by-field basis. Also, since the PIX ORDER and CURS SIZE bits are also sampled these functions will only change when vertical blanking is detected.

### 5.7.3 Other

Changes to the Cursor Color registers and the Cursor X and Y Hot Spot registers are propagated to the cursor logic as soon as they are made, so if they are updated while the cursor is being displayed the cursor image will be disturbed.

Changes to the cursor array are also propagated to the cursor logic as soon as they are made. Also, as noted above, microprocessor read accesses of the cursor array may interfere with the cursor display logic. For example, with a 32x32 cursor being displayed from slot 0, microprocessor read accesses to slot 1 may cause the display of the slot 0 cursor to be disturbed.

It is recommended that Cursor Array Reads and changes to the Cursor Color registers and the Cursor X and Y Hot Spot registers be made only when the cursor is disabled, off screen, or during vertical blanking time.

Table 8. Cursor Modes

CURSOR PIXELS	CURSOR MODE		
	Mode 0 CURSOR MODE = 01	Mode 1 CURSOR MODE = 10	Mode 2 CURSOR MODE = 11
00	Transparent	Cursor Color 1	Transparent
01	Cursor Color 1	Cursor Color 2	Transparent
10	Cursor Color 2	Transparent	Cursor Color 1
11	Cursor Color 3	Complement	Cursor Color 2

## 6.0 DAC Control

Several miscellaneous features of the DACs are controlled by the DAC Operation register.

### 6.1 SOG - Composite Sync-On-Green

When the SOG bit is set, the signal on the  $\overline{\text{HCSYNCIN}}$  input will be merged with the pixel data on the green DAC. The incoming signal may be inverted and/or delayed before presentation at the DAC.

### 6.2 BRB - Blank Red and Blue DACs

When this is set the red and blue DACs are set to the blanking level. This is intended for use when a monochrome display is driven by the green DAC.

### 6.3 DSR - DAC Slew Rate

This bit affects the rise and fall times of the DAC analog outputs (slew rate). The default value (off) uses a "slow" rate, typically 14 ns. When the bit is set to "on", the slew rate will be "fast", typically 2 ns. The rise and fall times are measured using the 10% point and 90% point.

The faster slew rate will yield the sharpest pixels if the monitor can support that rate. For some monitors it may be desirable to set the DACs to the slower slew rate.

### 6.4 DPE - DAC Blanking Pedestal Enable

When off, the DAC pedestal is disabled (blanking level = 0 IRE). When on, the pedestal is enabled (7.5 IRE).

## 7.0 Power Management

The following registers are used to control power dissipation:

- ❑ Power Management (index 0x0005)
- ❑ Miscellaneous Clock Control (index 0x0002)
- ❑ Sync Control (index 0x0003)
- ❑ Miscellaneous Control 1 (index 0x0070)

### 7.1 DAC Power

The analog portion of the DACs can be shut down with the DAC PWR bit of the Power Management register. A small amount of current (approximately 100  $\mu$ A) will continue to be drawn through the VREFIN input. This can be eliminated if the voltage on VREFIN is reduced to 0 V.

### 7.2 Driver Power

The power dissipated by the logic output signals can be reduced by 3-stating the drivers. This is done for the SCLK driver by setting the SCLK DSAB bit of the Miscellaneous Clock Control register. The DDOTCLK driver can also be 3-stated by setting the DDOT DSAB bit of the Miscellaneous Clock Control register. HSYNCOUT and VSYNCOUT are 3-stated by setting HSYN CNTL and VSYN CNTL bits of the Sync Control register. The SENSE output is 3-stated by setting the SENS DSAB bit of the Miscellaneous Control 1 register.

The remaining drivers are the microprocessor D[7:0] signals. These are normally 3-stated and will not dissipate power unless a microprocessor read is performed.

### 7.3 Clocking Power

Most of the digital logic power dissipation occurs as a result of clocking. The ICLK PWR, SCLK PWR, DDOT PWR, and SYNC PWR bits of the Power Management register are used to inhibit the digital logic clocking.

The ICLK PWR bit, when set, inhibits all internal clocking except for the following:

- ❑ The PLL.
- ❑ The palette arrays and the cursor array control logic. The clocks to the internal logic are left running because this is required for microprocessor access.
- ❑ SCLK and DDOTCLK - The circuitry that generates these clocks is left running in case external components need to run off these clocks.
- ❑ The horizontal and vertical sync delay circuits. These circuits are left running to allow sync signals to propagate to the display monitor.

When the ICLK PWR bit is set the DAC outputs will remain stuck at whatever was last clocked into the DACs, unless the DACs are shut down with DAC PWR.

The SCLK PWR bit may be set to disable the clocking to the SCLK generator. The resultant static SCLK output may be left at either the low or high state. As noted above, the SCLK output may be 3-stated with the SCLK DSAB bit of the Miscellaneous Clock Control register.

The DDOT PWR bit may be set to disable the clocking to the DDOTCLK generator. The resultant static DDOTCLK output may be left at either the low or high state. As noted above, the DDOTCLK output may be 3-stated with the DDOT DSAB bit of the Miscellaneous Clock Control register.

The SYNC PWR bit may be set to disable the clocking to the horizontal and vertical sync circuits. These outputs may be left at either the low or high state. (But note that the outputs can be forced high or low or 3-stated with the HSYN CNTL and VSYN CNTL bits of the Sync Control register.)

The starting and stopping of clocks with the SCLK PWR, DDOT PWR, and SYNC PWR bits is asynchronous. Thus, "chopped" pulses may be produced on the SCLK, DDOTCLK, HSYNCOUT and VSYNCOUT outputs when these bits are changed.

Similarly, changing the ICLK PWR bit can disturb the stopping and starting of the internal clocks such that the display is disturbed for a frame. It is recommended

that the DACs be blanked with the BLANK CNTL bit of the Miscellaneous Control 2 register before shutting off the clocks, and that a frame be run by after turning on the clocks before the DACs are unblanked again with BLANK CNTL.

## 7.4 PLL Power

The PLL uses approximately 3 mW of power. It can be shut off with the PLL ENAB bit of the Miscellaneous Clock Control register. This, in conjunction with turning off the DACs and 3-stating the drivers, produces the lowest power consumption.

Note that in general the PLL drives SCLK, and the incoming LCLK is generally derived externally from SCLK. If the PLL is disabled, SCLK will stop running regardless of the setting of SCLK PWR, DDOTCLK will stop running regardless of the setting of DDOT PWR, internal clocking will stop regardless of the setting of ICLK PWR, sync signal clocking will stop regardless of the setting of SYNC PWR, and external circuitry running off SCLK and/or DDOTCLK will stop running.

If EXTCLK is used instead of the PLL the same effect can be achieved by stopping EXTCLK.

## 8.0 Diagnostic Support

### 8.1 Data Masks

The Pixel data inputs may be masked by the VRAM Mask registers to diagnose frame buffer problems. Each active bit in the VRAM Mask register controls four bits of the pixel port. Masked bytes introduce zeroes into the data path.

### 8.2 MISR

The MISR employs a 24-bit shift register with feedback to accumulate a signature of the data presented to the DACs during one screen frame. Signature accumulation is controlled by vertical blanking detection and Miscellaneous Control 1 register bit 7. After MC1(7) changes from '0'b to '1'b, vertical blanking resets the signature to zero at the start of a frame. Signature accumulation ends when vertical blanking goes "on" to end a frame, regardless of the state of MC1(7). The MISR signature can now be read with three cycles from the microprocessor interface. MC1(7) must be written to a '0'b and then a '1'b before a new signature can be generated. In interlace mode, the MISR accumulates one complete frame starting with the ODD field.

### 8.3 DAC Comparators

Each DAC output is connected to a comparator. Both latched and unlatched copies of the comparator outputs can be read from the DAC Sense register. The logical AND of either the latched or unlatched comparator bits is presented on the SENSE output. The reference inputs of the comparators are connected to the chip CVREF pin. With the internally applied reference voltage of 0.35 V, the corresponding Sense bit will be '1'b when the DAC output is 0 to 0.28 V or '0'b when it is 0.42 V to 0.70 V. These values apply when the DAC is doubly terminated in 75  $\Omega$ , RREF=698  $\Omega$ , and no sync or blank is present.

## 9.0 Internal Register - Summary

Table 9 is a summary of the internal registers. Detailed descriptions are given in Section 10.0.

For correct operation, and to preserve upward compatibility, the registers listed as "Reserved" must not be written to. Within a register, individual bits listed as "Reserved" must be set to '0's.

Table 9. Internal Register Summary

RS[2:0]	Index	R/W	Reset Value	Register Name
000	-	✓	U	Palette Address (Write Mode)
001	-	✓	U	Palette Data
010	-	✓	U	Pixel Mask

## 10.0 Register Descriptions

### 10.1 Direct Access Registers

The direct access registers are addressed using RS[2:0] inputs.

#### Palette Address (Write Mode)

**RS[2:0]:** 000  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** WRITE Address - Palette address in write mode.

Operation of this register is discussed in 1.0 "Microprocessor Access" on page 1.

#### Palette Data

**RS[2:0]:** 001  
**Access:** Read/Write  
**Power on Value:** Undefined

The format of the palette data depends on the color resolution, 6 or 8 bit.

#### 6 bit color resolution

**Miscellaneous Control 2 COL RES = 0**

**Bits 7 - 6** 00  
**Bits 5 - 0** 6 bit palette data

On WRITES bits 7:6 from the microprocessor are discarded, bits 5:0 are written to bits 7:2 internally, and internal bits 1:0 are set to '00'. On reads internal bits 7:2 are read as bits 5:0, and bits 7:6 are returned as '00'.

#### 8 bit color resolution

**Miscellaneous Control 2 COL RES = 1**

**Bits 7-0** 8 bit palette data. Bits 7:0 are written/read internally as bits 7:0

Operation of this register is discussed in 1.0 "Microprocessor Access" on page 1.

#### Pixel Mask

**RS[2:0]:** 010  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Pixel Mask

In indirect color modes this register masks the pixel values used to index into the palettes. Each bit is ANDed with its corresponding pixel bit. A value of 0xff is required to pass the pixel values to the palettes unchanged.

The same mask is applied to each of the red, green, and blue pixel addresses into the palettes.

**Palette Address (Read Mode) / Palette Access State**

**RS[2:0]:** 011  
**Access:** Write  
**Power on Value:** -  
**Bits 7 - 0** READ Address - Palette address in read mode.

**RS[2:0]:** 011  
**Access:** Read  
**Power on Value:** Undefined  
**PADR RFMT:** 0  
**Bits 7 - 0** READ Address - Palette address in read mode.

**RS[2:0]:** 011  
**Access:** Read  
**Power on Value:** Undefined  
**PADR RFMT:** 1  
**Bits 7 - 2** Reserved  
**Bits 1 - 0** ACC STATE - Palette Access State. Reports which mode was used on last write of Palette Address Register.  
 00 Write Mode  
 11 Read Mode

Note that the palette address to be read is written into this register, but the contents that are read depends on the PADR RFMT bit in the Miscellaneous Control 1 register. Operation of these registers is discussed in 1.0 "Microprocessor Access" on page 1.

**Index Low**

**RS[2:0]:** 100  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Index Low

This register, together with Index High, forms the internal index register. It selects the register that will be accessed when the Indexed Data register is written or read.

**Index High**

**RS[2:0]:** 101  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 3** Reserved  
**Bits 2 - 1** Index High

This register provides the high-order bits of the internal index register.

If auto-increment is turned on, the resulting index is not defined if an increment past the maximum index value occurs.

**Indexed Data**

**RS[2:0]:** 110  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Indexed Data

A write or read to this register will write or read the register addressed by the internal index register (Index High and Index Low).

Following a write or read to Indexed Data, the index register will be incremented if auto-increment is turned on (INDX CNTL bit of the Index Control register).

## Index Control

**RS[2:0]:** 111  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 1** Reserved  
**Bit 0** INDX CNTL - Index Control. Controls auto-increment of the index register.  
 0 Off - no auto-increment.  
 1 On - the index register (Index High and Index Low) will increment by one following a write or read to Indexed Data.

## 10.2 Indexed Registers

The indexed registers are accessed by setting the desired address into the internal index register (Index High and Index Low) and writing or reading the Indexed Data register.

## 10.2.1 Miscellaneous Control

### Miscellaneous Control 1

**Index:** 0x0070  
**Access:** Read/Write  
**Power on Value:** 0x00  
**Bit 7** MISR CNTL  
 0 Off. If the MISR is running, it will stop at the beginning of the next frame.  
 1 On. The MISR will start accumulating a signature at the start of the next frame (end of vertical blanking).  
**Bit 6** VMSK CNTL - VRAM Mask Control  
 0 No VRAM masking.  
 1 The VRAM inputs on the PIX[63:00] inputs will be masked under control of the VRAM Mask High and VRAM Mask Low registers.  
 This bit has no effect when the VGA port is selected.  
**Bit 5** PADR RFMT - Palette Address Register (Read Mode) Format. Specifies the contents returned from the Palette Address register, read mode (RS[2:0] = 011)  
 0 Return the eight bits of the read address  
 1 Return the palette access state in the two low order bits  
**Bit 4** SENS DSAB - SENSE Driver Disable  
 0 SENSE driver enabled  
 1 SENSE driver disabled (3-stated)  
**Bit 3** SENS SEL - Sense Select. Selects which bit of the DAC Sense register is presented on the SENSE driver.  
 0 Bit 3 - Unlatched Sense  
 1 Bit 7 - Latched Sense  
**Bits 2 - 1** Reserved  
**Bit 0** VRAM SIZE - VRAM interface width  
 0 32 bits. PIX[31:0] used, PIX[63:32] ignored.  
 1 64 bits. PIX[63:00] used.  
 (This bit has no effect when the VGA port is selected.)

## Miscellaneous Control 2

7	6	5	4	3	2	1	0
PCLK SEL	INTL MODE	BLANK CNTL	RSVD	COL RES	BRDR/ INTL	PORT SEL	

**Index:** 0x0071

**Access:** Read/Write

**Power on Value:** 0x00

**Bits 7 - 6** PCLK SEL - Pixel Clock Select. Specifies the source of the internal pixel clock.

- 00 LCLK input
- 01 Internal PLL output
- 10 REFCLK input
- 11 Reserved

**Note:** A selection of 00 (LCLK input) for the pixel clock is required and only valid when PORT SEL = 0 (VGA data inputs), or 32 BPP is selected with a VRAM width of 32.

**Bit 5** INTL MODE - Interlace Mode. Controls effect of  $\overline{\text{BORDER/OE}}$  input on cursor when this input is used as the ODD/EVEN interlace control.

- 0 Non-interlaced. The  $\overline{\text{BORDER/OE}}$  input is ignored.
- 1 Interlaced. If the cursor is turned on, the  $\overline{\text{BORDER/OE}}$  input will be used to select display of the odd or even cursor rows.

This bit has no effect when BRDR/INTL (bit 1) is set '0' ( $\overline{\text{BORDER/OE}}$  used as BORDER input).

**Bit 4** BLANK CNTL - Blanking Control

- 0 Normal operation.
- 1 DACs are blanked. No pixel data is presented on the DACs, but all other operations remain normal, including the collection of a signature if the MISR is turned on.

**Bit 3**

**Bit 2**

RSVD - Reserved

COL RES - Color Resolution

0 6-bit

1 8-bit

With 6-bit color resolution only 6 bits of microprocessor data are loaded into the palettes. Microprocessor data bits D[5:0] are written to/read from palette bits [7:2]. Internally 00 is written to palette bits [1:0], and on reads D[7:6] are forced to 00.

Also with 6-bit color resolution the two low order bits presented from the palettes to the DACs are controlled by Palette Control bit 6BIT LIN.

With 8-bit color resolution all 8 bits from/to the microprocessor are written/read to the palette, and the 8 bits presented to the DACs are unmodified. The 6BIT LIN bit has no effect.

**Bit 1**

BRDR/INTL - Border/Interlace. Controls usage of  $\overline{\text{BORDER/OE}}$  input.

- 0  $\overline{\text{BORDER/OE}}$  input used to indicate "BORDER". (Interlace operation is not supported.)
- 1  $\overline{\text{BORDER/OE}}$  input used to indicate "ODD/EVEN". (Border operation is not supported.)

**Bit 0**

PORT SEL - Port Select

0 VGA Data inputs.

1 VRAM pixel port inputs.

## Miscellaneous Control 3

**Index:** 0x0072

**Access:** Read/Write

**Power on Value:** 0x00

**Bit 7** SWAP RB - Swap Red and Blue pixel components. In 16, 24, and 32 BPP, this bit causes the red and blue components of the pixels to be swapped. In indirect mode, the swapping takes place before the Palette.

0 Normal operation.

1 Swap Red and Blue components of the pixel. This bit only has an effect in 16, 24, and 32 BPP.

**Bits 6 - 2** Reserved

**Bit 1** SWAP NIB - Swap nibbles within bytes. Used with 4 BPP.

0 Use high nibble (e.g., PIX[07:04]) for first pixel, use low nibble (e.g., PIX[03:00]) for next pixel.

1 Use low nibble (e.g., PIX[03:00]) for first pixel, use high nibble (e.g., PIX[07:04]) for next pixel.

The same nibble order is applied to each of the incoming bytes. This bit has no effect if the pixel format is not 4 BPP.

**Bit 0** Reserved

This register has no effect when the VGA port is selected.

## Miscellaneous Clock Control

**Index:** 0x0002

**Access:** Read/Write

**Power on Value:** 0x00

**Bit 7** DDOT DSAB - DDOTCLK driver disable

DDOTCLK driver enabled

0 DDOTCLK driver enabled

1 DDOTCLK driver disabled (3-stated)

**Bit 6** SCLK DSAB - SCLK driver disable

0 SCLK driver enabled

1 SCLK driver disabled (3-stated)

**Bit 5** B24P DDOT - Selects which clock is driven on DDOTCLK when 24 Bit Packed Pixel format is selected.

0 Use divided Pixel PLL output under control of DDOT DIV bits.

1 Output the same signal as SCLK.

When a format other than 24 BPP Packed is selected, the B24P DDOT bit has no effect and the divided Pixel PLL output is used.

**Bit 4** SCLK INVT - Inverts the SCLK output.

**Bits 3 - 1** DDOT DIV - DDOTCLK divide factor. Specifies the divide factor applied to the internal Pixel PLL output to produce the DDOTCLK output signal.

000 Pixel PLL out/1

001 Pixel PLL out/2

010 Pixel PLL out/4

011 Pixel PLL out/8

100 Pixel PLL out/16

101 Reserved

110 Reserved

111 Reserved

**Bit 0** PPLL ENAB - Pixel PLL Enable

0 Pixel PLL programming disabled.

1 Pixel PLL programming enabled.

## Sync Control

**Index:** 0x0003**Access:** Read/Write**Power on Value:** 0x00

**Bit 7** DLY CNTL - Sync Delay Control. Specifies whether delay matching the pixel pipeline delay should be added to the horizontal sync signal.

0 Add matching delay

1 Do not add delay

This bit only has effect when the SOG bit of the DAC Operation register is off. If SOG is on (composite sync enabled) then matching pipeline delay is not added to horizontal sync.

**Bit 6** CSYN INVT - Invert incoming  $\overline{\text{HCSYNCIN}}$  when used as Composite Sync

0 Do not invert incoming

 $\overline{\text{HCSYNCIN}}$ 1 Invert incoming  $\overline{\text{HCSYNCIN}}$ 

**Bit 5** VSYN INVT - Vertical Sync Invert

0 Do not invert incoming

 $\overline{\text{VSYNIN}}$ 1 Invert incoming  $\overline{\text{VSYNIN}}$ 

**Bit 4** HSYN INVT - Invert incoming  $\overline{\text{HCSYNCIN}}$  when used as Horizontal Sync

0 Do not invert incoming

 $\overline{\text{HCSYNCIN}}$ 1 Invert incoming  $\overline{\text{HCSYNCIN}}$ 

**Bits 3 - 2** VSYN CNTL - Vertical Sync Output Control

00 Normal output

01  $\overline{\text{VSYNCOU}}$  forced high10  $\overline{\text{VSYNCOU}}$  forced low11  $\overline{\text{VSYNCOU}}$  disabled (3-stated)

**Bits 1 - 0** HSYN CNTL - Horizontal Sync Output Control

00 Normal output

01  $\overline{\text{HSYNCOU}}$  forced high10  $\overline{\text{HSYNCOU}}$  forced low11  $\overline{\text{HSYNCOU}}$  disabled (3-stated)

## Horizontal Sync Control

**Index:** 0x0004**Access:** Read/Write**Power on Value:** 0x00**Bits 7 - 4** Reserved

**Bits 3 - 0** HSYN POS - Horizontal Sync Position. Specifies number of additional pixel delays to add to the horizontal sync signal and the composite sync signal.

0000 0 pixels

0001 1 pixel

0010 2 pixels

0011 3 pixels

0100 4 pixels

0101 5 pixels

0110 6 pixels

0111 7 pixels

1000 8 pixels

1001 9 pixels

1010 10 pixels

1011 11 pixels

1100 12 pixels

1101 13 pixels

1110 14 pixels

1111 15 pixels

If the SOG bit of the DAC Operation register is on, the additional pixel delays are added to composite sync. If SOG is off, then the delays are added to horizontal sync, under the control of the DLY CNTL bit of the Sync Control register. (The additional delay specified by the Horizontal Position register will only be added if DLY CNTL is set to 0.)

## Power Management

- Index:** 0x0005  
**Access:** Read/Write  
**Power on Value:** 0x00  
**Bits 7 - 5** Reserved  
**Bit 4** SCLK PWR - SCLK Power Control  
     0 Normal Operation  
     1 Disable clocks to SCLK generator  
**Bit 3** DDOT PWR - DDOTCLK Power Control  
     0 Normal Operation  
     1 Disable clocks to DDOTCLK generator  
**Bit 2** SYNC PWR - Sync Power Control  
     0 Normal Operation  
     1 Disable clocks to horizontal and vertical sync circuits  
**Bit 1** ICLK PWR - Internal Clock Power Control  
     0 Normal Operation  
     1 Disable all internal clocks except those for the SCLK generator, DDOTCLK generator, and horizontal and vertical sync circuits.  
     A clock is left running to allow microprocessor access of the palette and cursor array, but otherwise the palette and cursor RAMs will not be clocked. The two RAMs will retain their contents.  
**Bit 0** DAC PWR - DAC Analog Power Control  
     0 Normal Operation  
     1 Disable analog power to the DACs

## DAC Operation

- Index:** 0x0006  
**Access:** Read/Write  
**Power on Value:** 0x00  
**Bits 7 - 4** Reserved  
**Bit 3** SOG - Composite Sync-On-Green  
     0 Sync is disabled on Green DAC.  
     1 Sync is enabled on Green DAC.  
**Bit 2** BRB - Blank Red and Blue DACs  
     0 Red and Blue DACs have normal function.  
     1 Red and Blue DACs are always blanked.  
**Bit 1** DSR - DAC Slew Rate  
     0 Slow - typically 14 ns  
     1 Fast - typically 2 ns  
**Bit 0** DPE - DAC blanking Pedestal Enable  
     0 Blanking pedestal disabled (0 IRE)  
     1 Blanking pedestal enabled (7.5 IRE)

## Palette Control

**Index:** 0x0007

**Access:** Read/Write

**Power on Value:** 0x00

**Bit 7** 6BIT LIN - 6 Bit Linear Color  
 0 Apply linear palette output  
 1 Do not apply linear palette output

This bit only has effect with indirect color modes, and when Color Resolution is set to 6 bits (Miscellaneous Control 2 COL RES bit = 0). For the 8 bits of palette output for each color, the high order two bits 7 and 6 will be substituted for the two low order bits 1 and 0.

**Bits 6 - 4** Reserved.

**Bits 3 - 0** PALETTE PARTITION - Selects which partition to use within the palettes when the pixel format is either 4 BPP, 15 BPP indirect color, or 16 BPP indirect color.

With 4 BPP the palettes are divided into 16 partitions. Each partition contains 16 entries. Bits 3 - 0 select 1 of the 16 partitions.

With 15 BPP (555) indirect color, the palettes are divided into 8 partitions. Each partition contains 32 entries. Bits 3 - 1 select 1 of the 8 partitions and bit 0 is not used.

With 16 BPP (565) indirect color, the palettes are divided into 4 partitions. Each partition contains 64 entries. All 64 entries of the Green palette are used in each partition. For the Red and Blue palettes only the first 32 entries of each partition are used. Bits 3 - 2 select 1 of the 4 partitions and bits 1 and 0 are not used.

The PARTITION bits have no effect when the pixel format is not 4 BPP, 15 BPP, or 16 BPP. Also, with 15 BPP and 16 BPP the PARTITION bits have no effect unless

1. Indirect color is chosen (16 BPP Control register bits B16 DCOL = 00), AND
2. Contiguous addressing is chosen (16 BPP Control register bit SPR/CNT = 1)

## System Clock Control

<b>Index:</b>	0x0008
<b>Access:</b>	Read/Write
<b>Power on Value:</b>	0x01
<b>Bit 7</b>	RSVD - Reserved
<b>Bit 6</b>	SYSC DSAB - SYSCLK driver disable
	0 SYSCLK driver enabled
	1 SYSCLK driver disabled (3-stated)
<b>Bits 5 - 2</b>	Reserved
<b>Bit 1</b>	SYSC SRC - SYSCLK output source
	0 SYSCLK PLL output
	1 REFCLK input
<b>Bit 0</b>	SPLL ENAB - System PLL enable
	0 SYSCLK PLL programming disabled
	1 SYSCLK PLL programming enabled

## 10.2.2 Pixel Representation

### Pixel Format

<b>Index:</b>	0x000a
<b>Access:</b>	Read/Write
<b>Power on Value:</b>	Undefined
<b>Bits 7 - 3</b>	Reserved
<b>Bits 2 - 0</b>	Pixel Format
	000 Reserved
	001 Reserved
	010 4 BPP
	011 8 BPP
	100 15/16 BPP
	101 24 BPP Packed
	110 32 BPP
	111 Reserved

This register has no effect when the VGA port is selected.

The 24 BPP Packed format requires the VRAM SIZE (Miscellaneous Control 1 register bit 0) to be set for 64 bits. If VRAM SIZE is set to 32 bits, the product operation will be undefined if the 24 BPP Packed format is selected.

## 8 Bit Pixel Control

**Index:** 0x000b  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 1** Reserved  
**Bit 0** B8 DCOL - 8 BPP Direct Color Control

0 Indirect Color (through the palette).  
 1 Direct Color (palette bypass). Since the same 8-bit value will be applied to each of the Red, Green, and Blue DACs a monochrome image will be displayed.

This register only affects 8 BPP mode.

## 16 Bit Pixel Control

**Index:** 0x000c  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 6** B16 DCOL - 16 BPP Direct Color Control

00 Indirect Color (always goes through the palette). Either the 555 or 565 format can be selected. The SPR/CNT bit determines if the access of the palettes is sparse or contiguous. If CNT (contiguous), then the PARTITION bits of the Palette Control register determine which partition of the palettes is used. If SPR (Sparse) the ZIB/LIN bit must be set to 0 (ZIB).

01 Dynamic Bypass. The high order bit of each 16-bit pixel (PIX[15], PIX[31], PIX[47], PIX[63]) is used to select on a pixel-by-pixel basis to either go through the palette (indirect color) or bypass the palette (direct color). When this mode is selected the following conditions apply:

1. The 555/565 bit has no effect. Internally, the pixel format is forced to 5 bits per color (555).
2. The SPR/CNT bit has no effect. Internally, sparse addressing (SPR) is forced for palette access.
3. The ZIB/LIN bit has no effect. Internally, the low order bits for each color are forced to '0's (ZIB) for both access of the palette (indirect color) and palette bypass (direct color).
4. The Pixel Mask is applied to the pixel data regardless of whether or not the palette is bypassed.

10 Reserved

- 11 Direct Color (always bypasses the palette). Either the 555 or 565 format can be selected. The ZIB/LIN bit determines the expansion to 24 bits (low order bit fill). The SPR/CNT bit has no effect.

**Bit 5**

BY16 POL - Bypass control bit polarity. Determines the meaning of the dynamic bypass control bit (PIX[15], PIX[31]).

0 Control Bit Forces Bypass  
**Control BitPixel Path**

0 Through Palette  
(Indirect Color)

1 Bypass Palette  
(Direct Color)

1 Control Bit Forces Lookup  
**Control BitPixel Path**

0 Bypass Palette  
(Direct Color)

1 Through Palette  
(Indirect Color)

The BY16 POL bit has no effect unless the B16 DCOL bits are set to 01.

**Bits 4 - 3**

Reserved

**Bit 2**

ZIB/LIN - Bit fill selection. For direct color this bit specifies how the low order bits of each color, R,G,B are filled when 555 or 565 formats are expanded to 24 bits.

0 ZIB - Zero Intensity Black. Low order bits are set to 0.

1 LIN - Linear. The low order bits are set to the values of the high order bits.

For indirect color if CNT (contiguous) addressing is selected, then ZIB/LIN has no effect. If SPR (sparse) addressing is selected then ZIB/LIN **must** be set to 0 (ZIB). The palette addressing is undefined if LIN bit fill is selected with sparse addressing.

**Bit 1**

555/565 - Selects 5 bits per color (555) or 5 red, 6 green, 5 blue (565).

0 555

1 565

**Bit 0**

SPR/CNT - Sparse/Continuous. In indirect mode, selects whether index into palette is sparse or contiguous.

0 Sparse

1 Continuous

This register only affects 15/16 BPP mode.

## 24 Bit Packed Pixel Control

**Index:** 0x000d

**Access:** Read/Write

**Power on Value:** Undefined

**Bits 7 - 1** Reserved

**Bit 0** B24P DCOL - 24 BPP Packed Direct Color Control

0 Indirect Color (through the palette).

1 Direct Color (palette bypass).

This register only affects 24 BPP Packed mode.

## 32 Bit Pixel Control

**Index:** 0x000e

**Access:** Read/Write

**Power on Value:** Undefined

**Bit 7 - 3** Reserved

**Bit 2** BY32 POL - Bypass control bit polarity. Determines the meaning of the dynamic bypass control bit (PIX[24], PIX[56]).

**0** Control Bit Forces Bypass

**Control BitPixel Path**

**0** Through Palette  
(Indirect Color)

**1** Bypass Palette  
(Direct Color)

**1** Control Bit Forces Lookup

**Control BitPixel Path**

**0** Bypass Palette  
(Direct Color)

**1** Through Palette  
(Indirect Color)

The BY32 POL bit has no effect unless the B32 DCOL bits are set to 01

## Bits 1 - 0

## B32 DCOL - 32 BPP Direct Color Control

**00** Indirect Color (always goes through the palette). 24 bits (8 bits each for Red, Green, Blue) are used to index into the palettes. The 8 high order bits (PIX[31:24], PIX[63:56]) are not used.

**01** Dynamic Bypass. A control bit in the high order byte (PIX[24], PIX[56]) is used to select on a pixel-by-pixel basis to either go through the palette (indirect color) or bypass the palette (direct color). The remaining bits in the high order byte (PIX[31:25], PIX[63:57]) are not used. In this mode, the Pixel Mask is applied to the pixel data regardless of whether or not the palette is bypassed.

**10** Reserved

**11** Direct Color (always bypasses the palette). 24 bits (8 bits each for Red, Green, Blue) are presented to the DACs. The 8 high order bits (PIX[31:24], PIX[63:56]) are not used.

This register only affects 32 BPP mode.

## 10.2.3 Pixel Clock Frequency Selection

### Pixel PLL Control 1

**Index:** 0x0010

**Access:** Read/Write

**Power on Value:** 0x00

**Bits 7 - 3** Reserved

**Bits 2 - 0** EXT/INT

Determines the source and selection for the Pixel PLL programming registers.

**000 External FS[1:0] inputs**

One of the F0 - F3 registers is selected with external signals FS[1:0]. The selected register provides the Pixel PLL VCO divider value. The Fixed Pixel PLL Reference Divider register is used to pre-scale the PLL reference clock.

**001 External FS[1:0] inputs (4 value M/N programming)**

Four pairs of registers M0/N0, M1/N1, M2/N2, M3/N3 are selected with external signals FS[1:0] to provide the VCO divider/reference divider inputs to the Pixel PLL.

The Fixed PLL Reference Divider register is not used.

**010 Pixel PLL Control 2 register bits [3:0] (16 value direct programming)**

One of the F0 - F15 registers is selected with Pixel PLL Control 2 register bits [3:0]. The selected register provides the Pixel PLL VCO divider value. The Fixed Pixel PLL Reference Divider register is used to pre-scale the Pixel PLL reference clock.

**011 Pixel PLL Control 2 register bits [2:0] (8 value M/N direct programming)**

Eight pairs of registers M0/N0, M1/N1, M2/N2, M3/N3, M4/N4, M5/N5, M6/N6, M7/N7 are selected with Pixel PLL Control 2 register bits [2:0] to provide the VCO divider/reference divider inputs to the Pixel PLL. The Fixed Pixel PLL Reference Divider register is not used. Pixel PLL Control 2 register bit 3 has no effect.

**100** Reserved

**101** Reserved

**110** Reserved

**111** Reserved

## Pixel PLL Control 2

**Index:** 0x0011  
**Access:** Read/Write  
**Power on Value:** 0x00  
**Bits 7 - 3** Reserved  
**Bits 3 - 0** INT FS - Internal Frequency Selection. Identifies which Pixel PLL programming registers to use when Pixel PLL Control 1 register bits EXT/INT specify internal frequency selection (EXT/INT = 010 or 011).

EXT/INT = 000		EXT/INT = 001	
FS[1:0]	Selected Register	FS[1:0]	Selected Register
00	F0	00	M0, N0
01	F1	01	M1, N1
10	F2	10	M2, N2
11	F3	11	M3, N3

**Note:** FS[1:0] are the chip inputs FS[1:0]. Pixel PLL Control 2 register is not used when Pixel PLL Control 1 register bits EXT/INT = 000 or 001.

EXT/INT = 010		EXT/INT = 011	
INT FS[3:0]	Selected Register	INT FS[2:0]	Selected Register
0000	F0	000	M0, N0
0001	F1	001	M1, N1
0010	F2	010	M2, N2
0011	F3	011	M3, N3
0100	F4	100	M4, N4
0101	F5	101	M5, N5
0110	F6	110	M6, N6
0111	F7	111	M7, N7
1000	F8	<b>Note:</b> When Pixel PLL Control 1 EXT/INT bits = 010 or 011, Pixel PLL Control 2 bits INT FS[3:0] select the frequency register(s). For EXT/INT = 011, INT FS[3] bit is not used and has no effect.	
1001	F9		
1010	F10		
1011	F11		
1100	F12		
1101	F13		
1110	F14		
1111	F15		

## Fixed Pixel PLL Reference Divider

**Index:** 0x0014  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 5** Reserved  
**Bits 4 - 0** REF DIV COUNT - Reference Divide Count

## F0-F15: Pixel Frequency 0 to Frequency 15

**Index:** 0x0020 - 0x002f  
**Access:** Read/Write  
**Power on Value:** 0x00  
**Bits 7 - 6** DF - Desired Frequency  
**Bits 5 - 0** VCO DIV COUNT - VCO Divide Count

The above register diagram shows the format for the 16 pixel frequency registers F0 - F15. This format is selected when the EXT/INT bits (Pixel PLL Control 1 register, bits 2:0) = 000 or 010. The selected F0-F15 register provides the Pixel PLL with the DF value and the VCO divide count. All 16 frequency registers work with the same reference divide count, provided by the Fixed Pixel PLL Reference Divider register.

These 16 registers have a different format (M, N) (shown on the following page), when EXT/INT = 001 or 011.

## M0-M7, N0-N7

**Index:** 0x0020, 0x0022, 0x0024, 0x0026, 0x0028, 0x002A, 0x002C, 0x002E  
**Access:** Read/Write  
**Power on Value:** 0x00  
**Bits 7 - 6** DF - Desired Frequency  
**Bits 5 - 0** VCO DIV COUNT - VCO Divide Count

**Index:** 0x0021, 0x0023, 0x0025, 0x0027, 0x0029, 0x002B, 0x002D, 0x002F  
**Access:** Read/Write  
**Power on Value:** 0x00  
**Bits 7 - 5** Reserved  
**Bits 4 - 0** REF DIV COUNT - Reference Divide Count

The above diagrams show the formats for the 8 'M' and 8 'N' pixel frequency registers. These formats are selected when the EXT/INT bits (Pixel PLL Control 1 Register, bits 2:0) = 001 or 011.

The 8 registers are grouped into four pairs, M0/N0, M1/N1, M2/N2, M3/N3. For a given pair, the 'M' register provides the Pixel PLL with the DF value and the VCO divide count, and the 'N' register provides the Pixel PLL with the reference divide count.

As described above these 16 registers have a different format (F) when EXT/INT = 000 or 010.

## 10.2.4 System Clock Frequency Selection

### System PLL Reference Divider

**Index:** 0x0015  
**Access:** Read/Write  
**Power on Value:** 0x08  
**Bits 7 - 5** Reserved  
**Bits 4 - 0** REF DIV COUNT - Reference Divide Count

### System PLL VCO Divider

**Index:** 0x0016  
**Access:** Read/Write  
**Power on Value:** 0x41  
**Bits 7 - 6** DF - Desired Frequency  
**Bits 5 - 0** VCO DIV COUNT - VCO Divide Count

The System PLL Reference Divider and VCO Divider registers provide the programming values for the system clock (SYSCLK) PLL. The power on values will cause the PLL to produce a SYSCLK frequency of 33 MHz if the incoming reference clock (REFCLK) is 16 MHz.

## 10.2.5 Cursor

## Cursor Control

Index: 0x0030

Access: Read/Write

Power on Value: 0x00

**Bits 7 - 6** SMLC PART - Small Cursor Partition. Selects 1 of 4 partitions within the cursor array to use for the 32x32 cursor:

00 0x0100 - 0x01ff

01 0x0200 - 0x02ff

10 0x0300 - 0x03ff

11 0x0400 - 0x04ff

These bits have no effect when the cursor size is 64x64.

**Bit 5** PIX ORDR - Pixel Order. Specifies ordering of pixel bits in the bytes of the cursor array.

0 Right-to-left

1 Left-to-right

**Bit 4** LOC READ - Location Read-back Value. Specifies the value obtained by microprocessor reads of the Cursor X Low, Cursor X High, Cursor Y Low, and Cursor Y High registers.

0 Written Value - the value last written.

1 Actual Location - the location presently used for display. This will be different than the written value if a location register has been written but the location has not yet been updated. Following a cursor location update the "Written Value" and the "Actual Location" will be the same.

Bit 3

UPDT CNTL - Cursor Location Update Control. Controls when Cursor Location registers are sampled to change the cursor position.

0 Delayed - A write to the Cursor Y High register arms the circuitry for the update. The position is then updated (the cursor moves to the new location) when a vertical blanking period is detected.

1 Immediate - Move the cursor immediately following a write to any of the Cursor X Low, Cursor X High, Cursor Y Low, or Cursor Y High registers.

Bit 2

Cursor Size

0 32x32

1 64x64

Bits 1 - 0

Cursor Mode

00 OFF

01 Mode 0 (3 colors)

10 Mode 1 (2 colors and highlighting)

11 Mode 2 (2 colors)

**Cursor X Low****Index:** 0x0031**Access:** Read/Write**Power on Value:** Undefined**Bits 7 - 0** Cursor X Low. The low order bits of the cursor X (horizontal) position.

A write to this register will update the cursor position:

1. When both the Cursor Y High register is written and vertical blanking is detected, OR
2. Immediately

under control of the UPDT CNTL bit of the Cursor Control register.

The value read back:

1. Written Value, or
2. Actual Location

is controlled by the LOC READ bit of the Cursor Control register:

**Cursor X High****Index:** 0x0032**Access:** Read/Write**Power on Value:** Undefined**Bit 7** Sign

**Bits 6 - 4** SIGN EXTND - Sign Extended. These bits are always the same as bit 7. On a write these bits are discarded and replaced with the value written to bit 7. On a read they will return the same value as bit 7.

**Bits 3 - 0** Cursor X High. The high order bits of the cursor X (horizontal) position.

Cursor X High and Cursor X Low form a combined register that holds a signed cursor X position in two's complement form. The X position range is -4096 to +4095.

A write to this register will update the cursor position:

1. When both the Cursor Y High register is written and vertical blanking is detected, OR
2. Immediately

under control of the UPDT CNTL bit of the Cursor Control register

The value read back:

1. Written Value, or
2. Actual Location

is controlled by the LOC READ bit of the Cursor Control register.

## Cursor Y Low

**Index:** 0x0033

**Access:** Read/Write

**Power on Value:** Undefined

**Bits 7 - 0** Cursor Y Low. The low order bits of the cursor Y (vertical) position.

A write to this register will update the cursor position:

1. When both the Cursor Y High register is written and vertical blanking is detected, or
2. Immediately

under control of the UPDT CNTL bit of the Cursor Control register.

The value read back:

1. Written Value, or
2. Actual Location

is controlled by the LOC READ bit of the Cursor Control register.

## Cursor Y High

**Index:** 0x0034

**Access:** Read/Write

**Power on Value:** Undefined

**Bit 7** Sign

**Bits 6 - 4** SIGN EXTND - Sign Extended.

These bits are always the same as bit 7. On a write these bits are discarded and replaced with the value written to bit 7. On a read they will return the same value as bit 7.

**Bits 3 - 0** Cursor Y High. The high order bits of the cursor Y (vertical) position.

Cursor Y High and Cursor Y Low form a combined register that holds a signed cursor Y position in two's complement form. The Y position range is -4096 to +4095.

A write to this register will update the cursor position:

1. When vertical blanking is detected, or
2. Immediately

under control of the UPDT CNTL bit of the Cursor Control register.

The value read back:

1. Written Value, or
2. Actual Location

is controlled by the LOC READ bit of the Cursor Control register.

**Cursor Hot Spot X**

**Index:** 0x0035  
**Access:** Read/Write  
**Power on Value:** Undefined  
*32x32 Cursor*

**Bits 7 - 5** Reserved  
**Bits 4 - 0** HOT SPOT X. Specifies which pixel in a cursor row is the X position pixel.

*64x64 Cursor*

**Bits 7 - 6** Reserved  
**Bits 5 - 0** HOT SPOT X. Specifies which pixel in a cursor row is the X position pixel.

**Cursor Hot Spot Y**

**Index:** 0x0036  
**Access:** Read/Write  
**Power on Value:** Undefined  
*32x32 Cursor*

**Bits 7 - 5** Reserved  
**Bits 4 - 0** HOT SPOT Y. Specifies which pixel in a cursor column is the Y position pixel.

*64x64 Cursor*

**Bits 7 - 6** Reserved  
**Bits 5 - 0** HOT SPOT Y. Specifies which pixel in a cursor column is the Y position pixel.

**Cursor Color 1 Red**

**Index:** 0x0040  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Cursor Color 1 Red

**Cursor Color 1 Green**

**Index:** 0x0041

**Index:** 0x0046  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Cursor Color 3 Red

## Cursor Color 3 Green

**Index:** 0x0047  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Cursor Color 3 Green

## Cursor Color 3 Blue

**Index:** 0x0048  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Cursor Color 3 Blue

## 10.2.6 Border Color

### Border Color Red

**Index:** 0x0060  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Border Color Red

### Border Color Green

**Index:** 0x0061  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Border Color Green

### Border Color Blue

**Index:** 0x0062  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bits 7 - 0** Border Color Blue

## 10.2.7 Diagnostic Support

### Revision Level

**Index:** 0x0000  
**Access:** Read Only  
**Power on Value:** Revision Level  
**Bits 7 - 0** Product Revision Level

The value in this register indicates the revision level of the product.

### ID

**Index:** 0x0001  
**Access:** Read Only  
**Power on Value:** 0x02  
**Bits 7 - 0** Product Identification Code

This register distinguishes among the various members of the IBM Microelectronics Palette DAC family. The value of 0x02 indicates that this product is one of several that have two clock generators.

### DAC Sense

**Index:** 0x0082  
**Access:** Read Only  
**Power on Value:** Undefined  
**Bit 7** LSNS - Latched Sense  
**Bit 6** LBLU COMP - Latched Blue DAC Comparator Output  
**Bit 5** LGRN COMP - Latched Green DAC Comparator Output  
**Bit 4** LRED COMP - Latched Red DAC Comparator Output  
**Bit 3** SENS - Sense  
**Bit 2** BLU COMP - Blue DAC Comparator Output  
**Bit 1** GRN COMP - Green DAC Comparator Output  
**Bit 0** RED COMP - Red DAC Comparator Output

Bits 2,1,0 are the outputs of the three DAC reference comparators. The DAC output voltages are compared against the 0.35 V internal reference voltage (presented on COMPVREF). These bits are the "raw" outputs of the comparators.

Bits 6,5,4 are latched copies of bits 2,1,0. The latches are clocked during active line time (when  $\overline{\text{BLANK}}$  [and  $\overline{\text{BORDER}}$ , when a border is used] are both high).

Bit 3 (Sense) represents the combined status of bits 2,1,0. If any of these bits is 0, bit 3 will be 0.

Bit 7 (Latched Sense) represents the combined status of bits 6,5,4. If any of these bits is 0, bit 7 will be 0.

Either bit 3 or bit 7 will be presented on the  $\overline{\text{SENSE}}$  output, depending on the SENS SEL bit of the Miscellaneous Control 1 register.

If the selected bit is 0,  $\overline{\text{SENSE}}$  will be low.

If the selected bit is 1,  $\overline{\text{SENSE}}$  will be high.

## MISR Red

**Index:** 0x0084  
**Access:** Read Only  
**Power on Value:** Undefined  
**Bits 7 - 0** Multiple Input Signature Register Red

This register along with MISR GREEN and MISR BLUE is used to accumulate a diagnostic signature on the values presented to the DACs. The input to the Red DAC is the parallel data input to this portion of the MISR.

## MISR Green

**Index:** 0x0086  
**Access:** Read Only  
**Power on Value:** Undefined  
**Bits 7 - 0** Multiple Input Signature Register Green

This register along with MISR RED and MISR BLUE is used to accumulate a diagnostic signature on the values presented to the DACs. The input to the Green DAC is the parallel data input to this portion of the MISR.

## MISR Blue

**Index:** 0x0088  
**Access:** Read Only  
**Power on Value:** Undefined  
**Bits 7 - 0** Multiple Input Signature Register Blue

This register along with MISR RED and MISR GREEN is used to accumulate a diagnostic signature on the values presented to the DACs. The input to the Blue DAC is the parallel data input to this portion of the MISR.

**Note:** The reset, accumulation, and hold function of the MISR is controlled by the MISR CNTL bit of the Miscellaneous Control 1 register, and the BLANK input. See 8.0 "Diagnostic Support" on page 23 for more information.

## PLL VCO Divider Input

**Index:** 0x008e  
**Access:** Read Only  
**Power on Value:** 0x00  
**Bits 7 - 6** DF - Desired Frequency  
**Bits 5 - 0** VCO DIV COUNT - VCO Divide Count

This register allows readback of the selected PLL VCO divider input. It is one of these registers:

- ☐ F0, F1, F2, F3, F4, F5, F6, F7, F8, F9, F10, F11, F12, F13, F14, F15
- ☐ M0, M1, M2, M3, M4, M5, M6, M7

as determined by the PLL Control 1 EXT/INT bits (2:0), the inputs FS[3:0], and PLL Control 2 INT FS bits (3:0).

## PLL Reference Divider Input

**Index:** 0x008f  
**Access:** Read Only  
**Power on Value:** Undefined  
**Bits 7 - 5** Reserved  
**Bits 4 - 0** REF DIV COUNT - Reference Divide Count

This register allows readback of the input to the PLL reference divider.

- ☐ Fixed PLL Reference Divider
- ☐ N0, N1, N2, N3, N4, N5, N6, N7

as determined by the PLL Control 1 EXT/INT bits (2:0), the inputs FS[3:0], and PLL Control 2 INT FS bits (3:0).

## VRAM Mask Low

7	6	5	4	3	2	1	0
MASK	MASK	MASK	MASK	MASK	MASK	MASK	MASK
31:28	27:24	23:20	19:16	15:12	11:08	07:04	03:00

**Index:** 0x0090  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bit 7** Mask VRAM PIX inputs 31:28  
**Bit 6** Mask VRAM PIX inputs 27:24  
**Bit 5** Mask VRAM PIX inputs 23:20  
**Bit 4** Mask VRAM PIX inputs 19:16  
**Bit 3** Mask VRAM PIX inputs 15:12  
**Bit 2** Mask VRAM PIX inputs 11:08  
**Bit 1** Mask VRAM PIX inputs 07:04  
**Bit 0** Mask VRAM PIX inputs 03:00

A value of 1 on any of the bits in this register masks (forces to 0) the corresponding received VRAM pixel port inputs. This register has no effect on the inputs unless enabled with the VMSK CNTL bit of the Miscellaneous Control 1 register.

## VRAM Mask High

7	6	5	4	3	2	1	0
MASK	MASK	MASK	MASK	MASK	MASK	MASK	MASK
63:60	59:56	55:52	51:48	47:44	43:40	39:36	35:32

**Index:** 0x0091  
**Access:** Read/Write  
**Power on Value:** Undefined  
**Bit 7** Mask VRAM PIX inputs 63:60  
**Bit 6** Mask VRAM PIX inputs 59:56  
**Bit 5** Mask VRAM PIX inputs 55:52  
**Bit 4** Mask VRAM PIX inputs 51:48  
**Bit 3** Mask VRAM PIX inputs 47:44  
**Bit 2** Mask VRAM PIX inputs 43:40  
**Bit 1** Mask VRAM PIX inputs 39:36  
**Bit 0** Mask VRAM PIX inputs 35:32

A value of 1 on any of the bits in this register masks (forces to 0) the corresponding received VRAM pixel port inputs. This register has no effect on the inputs unless enabled with the VMSK CNTL bit of the Miscellaneous Control 1 register.

**Note:** The mask function is intended to be used with the MISR for diagnostics. See 8.0 "Diagnostic Support" on page 23 for more details.

## 11.0 Pin Descriptions

Table 10. Pin Descriptions

Signal	Type	Pin(s)	Description
<b>Clocks and Clock Controls</b>			
REFCLK	I	80	Reference Clock. A fixed frequency of 2 MHz to 100 MHz applied to this pin provides the reference clock for the programmable pixel and system clock PLLs. When the Direct Programming method is used the REFCLK frequency range is 4 MHz to 62 MHz on 2 MHz boundaries.
FS[1:0]	I	96,83	Frequency Select. These two inputs select one of four sets of registers containing the programming values for the pixel PLL.
DDOTCLK	O	116	Divided Dot Clock. The output of the pixel PLL, divided by 1, 2, 4, 8 or 16. The divide factor is under register control. In 24 BPP Packed pixel mode the SCLK signal can be selected for this output instead of the divided pixel PLL output, under register control. This output can be 3-stated under register control.
SCLK	O	113	Serial Clock. A divided version of the pixel PLL, where the divide ratio is determined by the required bandwidth of the incoming pixels. When the PIX port is selected, the SCLK frequency is a function of the VRAM width and the pixel format (bits per pixel). SCLK is equal to the pixel PLL output when the VGA port is selected. This output can be 3-stated under register control.
LCLK	I	109	Load Clock. Latches data from the PIX port, the VGA port, and the video control inputs.
SYSCLK	O	75	System Clock. The output of the SYSCLK programmable PLL. Also the REFCLK input can be steered to this output. This output can be 3-stated under register control.
<b>Video Data Inputs</b>			
PIX[63:0]	I	10,9,8,7,67,66,65,64, 123,122,121,120,119,118, 117,140,139,138,137,136, 135,134,133,74,71,70,69, 68,6,5,4,3,2,1,144,143, 131,130,129,128,127,126, 125,124,56,55,54,53,52, 50,63,48,47,62,46,61,60, 59,58,45,44,57,49,43	Pixel data in from VRAMs.  Pixel data in can be selected as 64 or 32 bits using the VRAM SIZE bit of the Miscellaneous Control 1 register. For 32 bit use inputs PIX[63:32] are not used.  Latched on rising edge of LCLK.
VGA[7:0]	I	42,41,40,39,38,37,36,35	VGA data in. Latched on rising edge of LCLK.
Type: I = Input, O = Output, B = Bidirectional, C = Component			

Table 10. Pin Descriptions (Continued)

Signal	Type	Pin(s)	Description
<b>Video Control Inputs</b>			
<b>BLANK</b>	I	78	A low level indicates blanking time; a high level indicates active picture time (pixel data, cursor, or border displayed). Latched on rising edge of LCLK.
<b>BORDER/OE</b>	I	79	This is a shared input. It may be used either as a border indicator, or as an interlace control. Within this document, this input may be referred to as <b>BORDER</b> or <b>ODD/EVEN</b> , depending on usage.  When used as <b>BORDER</b> : When <b>BLANK</b> is high (picture time), a low level on <b>BORDER</b> indicates the contents of the border registers should be displayed, and a high level indicates that pixel data or cursor should be displayed. When <b>BLANK</b> is low (blanking time) <b>BORDER</b> must be low. If no border is to be displayed <b>BORDER</b> should be tied to <b>BLANK</b> . Latched on rising edge of LCLK.  When used as <b>O/E (ODD/EVEN)</b> : Used in interlace mode to identify a field as odd or even; determines which row of cursor RAM to display if the cursor is enabled. In this usage the input should only change during vertical blanking.
<b>HCSYNCIN</b>	I	77	This is a shared input. It may be used either as horizontal sync in or composite sync in.  When used as Horizontal Sync In, a delayed copy of this signal is presented on <b>HSYNCOUT</b> to align the timing of horizontal sync to the pixel data at the DACs. The incoming polarity can be inverted under register control. Latched on rising edge of LCLK.  When used as Composite Sync In, when enabled, this signal is presented on the Green DAC with the video data. The signal is delayed to match the delay of the pixel data. The incoming polarity can be inverted under register control. Latched on rising edge of LCLK
<b>VSYN CIN</b>	I	76	Vertical Sync In. A copy of this signal is presented on <b>VSYN COUT</b> . The incoming polarity can be inverted under register control.
<b>Video Control Outputs</b>			
<b>HSYN COUT</b>	O	32	Horizontal Sync Out. This is a copy of <b>HCSYN CIN</b> (or inverted <b>HCSYN CIN</b> ), delayed by the same number of pixel clocks as seen by the pixel data at the input to the DACs. It can be forced to a high or low level or 3-stated under register control. The amount of delay may also be adjusted with the Horizontal Sync Position register.
<b>VSYN COUT</b>	O	12	Vertical Sync Out. This is a copy of <b>VSYN CIN</b> (or inverted <b>VSYN CIN</b> ). It can be forced to a high or low level or 3-stated under register control.
Type: I = Input, O = Output, B = Bidirectional, C = Component			

Table 10. Pin Descriptions (Continued)

Signal	Type	Pin(s)	Description
<b>Microprocessor Interface</b>			
$\overline{WR}$	I	103	Write strobe. Writes data into the register selected by RS[2:0]. The leading edge samples RS[2:0]. The trailing edge clocks the data on D[7:0] into the selected register.
$\overline{RD}$	I	102	Read strobe. Drives the register contents selected by RS[2:0] onto D[7:0]. The leading edge samples RS[2:0]. When $\overline{RD}$ is low the D[7:0] drivers are enabled.
RS[2:0]	I	101,100,99	Register selects. Sampled on the leading edge of $\overline{WR}$ and $\overline{RD}$ and used to select one of the direct access registers. See Direct Access Registers for more details.
D[7:0]	B	112,111,110,108, 107,106,105,104	Bidirectional data bus for internal register write and read data. The drivers are enabled when $\overline{RD}$ is low, otherwise they are 3-stated.
<b>Miscellaneous</b>			
RESET	I	81	Internal register and PLL reset. Resets bits of certain registers to a given state. (Generally set to VGA operation. See register descriptions for details.) Also initializes PLL circuits. A reset is <b>required</b> following power on to guarantee proper PLL operation.
VGAMODE	O	98	Indicates the VGA port is the selected pixel port. This output is the inverted state of Miscellaneous Control 2 register bit 0 (PORT SEL).
SENSE	O	11	DAC sense comparator output. Goes low when one or more of the three DAC outputs is above the comparator voltage reference. The three individual comparator outputs are also available as register bits. Either unlatched or latched comparator outputs may be selected for generating the SENSE output, under register control. This output can be 3-stated under register control.
<b>Video Outputs</b>			
RED	O	20	RED video out.
GREEN	O	28	GREEN video out.
BLUE	O	30	BLUE video out.
Type: I = Input, O = Output, B = Bidirectional, C = Component			

Table 10. Pin Descriptions (Continued)

Signal	Type	Pin(s)	Description
<b>DAC Support</b>			
VREFIN	C	18	Voltage Reference In for the DACs. Connect 1.235 V to this pin and decouple it with a 10 nF ceramic capacitor to DACGND.
RREF	C	26	Resistor Reference. Connect a resistor from this pin to DACGND. This pin connects to an internal op amp which compares the voltage on this pin to that of VREFIN, and adjusts the current flowing out of the RREF pin such that the voltage developed across the reference resistor matches VREFIN. The value of the resistor determines the full scale output current of the DACs. A value of 698 $\Omega$ is recommended.
CVREF	C	15	Comparator Voltage Reference. An internal voltage divider between VREFIN and DACGND sets this pin to 0.35V. It is used internally by comparators to sense the values of the DAC outputs. Decouple this pin to DACGND with a 1nF ceramic capacitor.
GREF	C	14	DAC Gate Reference. Output of DAC op amp and input to gates of devices connecting DACVDD to the DAC current switches. Decouple this pin to DACVDD with a 1 nF ceramic capacitor.
<b>PLL Support</b>			
RCI0	C	92	Pixel PLL Loop filter. Connect to parallel 1.3 K $\Omega$ resistor and 680 pF capacitor. Return parallel resistor and capacitor to RCRET0 through 8.2 nF capacitor.
RCRET0	C	91	Pixel PLL Loop filter return. Connect as described above under RCI0.
RCI1	C	87	SYSCLK PLL Loop filter. Connect to parallel 1.3 K $\Omega$ resistor and 680 pF capacitor. Return parallel resistor and capacitor to RCRET1 through 8.2 nF capacitor.
RCRET1	C	86	SYSCLK PLL Loop filter return. Connect as described above under RCI1.
Type: I = Input, O = Output, B = Bidirectional, C = Component			

Table 10. Pin Descriptions (Continued)

Signal	Type	Pin(s)	Description
<b>Manufacturing Test</b>			
TESTMODE	I	94	This input must be low for functional use. Leave it unconnected. An internal pulldown resistor causes this input to be at ground level.
DII	I	84	This input must be high for functional use.
DI2	I	85	This input must be high for functional use.
RI	I	95	This input must be high for functional use. An external 1 K $\Omega$ resistor to VDD is recommended.
<b>Power and Ground</b>			
VDD		34,73,115,142	Logic Power (3.3 V)
GND		17,33,51,72,82,97,114,132,141	Logic Ground
DACVDD		13,19,21,24,27,29	DAC Power (3.3 V)
DACGND		16,22,23,25,31	DAC Ground
PLLVDD		90,93	PLL Power (3.3 V)
PLLGND		88,89	PLL Ground
Type: I = Input, O = Output, B = Bidirectional, C = Component

## Notes:

- Supply current is the total of  $I_{VDD}$ ,  $I_{VDDDAC}$  and  $I_{VDDPLL}$ .
- Typical power dissipation is for VDD, VDDDAC, VDDPLL = 3.3 V, TA = 20 °C, with typical pixel patterns such as displayed with graphical user interfaces, and  
170 MHz part running at 135 MHz (e.g., for 1280 x 1024 screen)  
220 MHz part running at 216 MHz (e.g., for 1600 x 1280 screen)
- Maximum power dissipation is for VDD, VDDDAC, VDDPLL = 3.6 V, TA = 0 °C, with alternating full black/full white pixels running at the maximum specified frequency (170/220 MHz)

## 16.0 Change Summary

Table 19. Summary of Changes

Date	Changes
05/24/94	1. First publication.
06/14/94	<ol style="list-style-type: none"> <li>Section 3.3.4, "24 BPP," and "Pixel Format Register" description redefined stating that if 24 BPP Packed format is selected with the Pixel Format register, but the VRAM SIZE bit in the Miscellaneous Control 1 register is set for 32 bits, then the product operation is undefined.</li> <li>Section 10.2.7, "Diagnostic Support," the Power on Value for the ID register is changed from 0x01 to 0x02.</li> <li>Cross references expanded to include section numbers with headings where applicable.</li> <li>Expanded the table of contents to include register description headings and page numbers.</li> <li>Miscellaneous typographical errors corrected.</li> </ol>
07/20/94	<ol style="list-style-type: none"> <li>Corrected description of pixel PLL operation following a reset. Section 2.7.1, "Pixel PLL," now indicates that the PLL will run at a frequency in the kilohertz range following a reset (or when it is "disabled"). The values of the PLL Control 2 register, and the PLL programming registers F0 - F15 are now shown to have reset values of 0x00. These values will cause the pixel frequency to be in the range of 1.25 KHz to 62.5 KHz following a reset.  Also indicated that SYSCLK PLL will run in kilohertz range when disabled. The SYSCLK PLL operation following a reset continues to be the same: it comes up enabled at a pre-programmed frequency.</li> <li>In section 2.8, "PLL Programming," a statement was removed that indicated a check for minimum VRF was unnecessary for M over N programming with an input reference above 4 MHz. This is not true.</li> </ol>
03/17/95	<ol style="list-style-type: none"> <li>Removed "PRELIMINARY" designation.</li> <li>In "Product Highlights" on cover page, fixed typo. Package is 144 QFP, not 208 QFP.</li> <li>Added a note to section 2.5.1, "DDOTCLK," that there is no particular phase relationship between DDOTCLK and SCLK.</li> <li>Added section 2.13, "PLL Interaction," describing a programming requirement to prevent the two PLLs from interfering with each other.</li> <li>Added note to Section 9.0, "Internal Register - Summary," requiring setting of reserved register bits to '0', and not writing to reserved registers.</li> <li>Fixed typo in Table 10. "Pin Descriptions" on page 50. SCLK is pin 113, not 75.</li> <li>Changed part numbers for ordering In Table 18 (e.g. from "IBM37-RGB524-CF-17C" to "IBM 37RGB524 CF 17 A".</li> <li>Added appendix A.0 "Relationship to RGB624" on page 62.</li> <li>Added appendix C.0 "Switching Into VGA Mode" on page 64. This appendix recommends a particular software sequence for switching from the VRAM port to the VGA port, for compatibility with the RGB513, RGB514, and RGB525 products.</li> <li>Added appendix D.0 "-A Revision Level" on page 65. This describes a fix to a problem with the SCLK INVT function.</li> </ol>

## **Appendix**

### **A.0 Relationship to RGB624**

The RGB524 Palette DAC uses a 144-pin QFP package and has the following features: 64-bit pixel data path, packed 24-bit pixels, two on-chip programmable clock generators, video clocks up to 220 MHz, on-chip 64x64 hardware cursor, triple monotonic 8-bit DAC's to display 16.8 million colors.

Another product is available, the RGB624, that is pin-for-pin compatible with the RGB524, and shares the same register set. In addition, the RGB624 offers the following features:

- ❑ YUV pixel support, with fully programmable YUV-RGB conversion.
- ❑ Mixed YUV/RGB pixels, with selection based on a "tag" bit.
- ❑ Overlay/Underlay layers, with selection based on a "chroma key" or "luma key"
- ❑ An "advanced function" hardware cursor. This provides the same cursor functions as the RGB524, and in addition provides a "translucent" cursor in which the underlying pixels appear to "shine through" the displayed cursor.
- ❑ Enhanced PLL programming. While retaining the PLL programming features of previous generation RGB Palette DACs for compatibility, the RGB624 offers a new mode for programming the PLLs. Called "full M over N", this new mode has larger M and N ranges, and removes restrictions on M and N combinations that exist with the previous generation. Full M over N gives finer control in programming for the desired output frequencies, and allows the internal operating points of the PLLs to be fine tuned.

In general the RGB524 can be used as the "base feature" set for a graphics adapter, and the additional features of the RGB624 can be added to an existing design by "dropping in" the RGB624, and enabling the new features by providing additional programming. See the RGB624 data sheet (Document number IOG624DSU) for a detailed description of the new features.

## B.0 Relationship to Previous Generation RGB525

The RGB524 is a superset of the RGB525 and is generally upward register compatible with the RGB525. The principal differences are these:

- ❑ A second programmable clock generator is added for driving SYSCLK. This clock is also known as MCLK.
- ❑ The RGB524 speed ratings are 170 and 220 MHz, whereas the RGB525 is offered in 170, 220, and 250 MHz speeds.
- ❑ The RGB524 uses a 144 pin QFP, whereas the RGB525 uses a 208 pin QFP.

In addition, there are some I/O and register bit differences to accommodate the smaller package size and to add the second clock generator (PLL). The RGB524 share these same differences from the RGB525:

11. The HCSYNCIN input on the RGB524 is two separate inputs on the RGB525: HSYNCIN and CSYNCIN.
12. The BORDER/OE input on the RGB524 is two separate inputs on the RGB525: BORDER and ODD/EVEN. A new bit, BRDR/INTL, is added to the Miscellaneous Control 2 register to select the function of this input.
13. The RGB525 has an input, "EXTCLK," which can serve as an alternate to the REFCLK input, either as the input reference to the PLL, or as the pixel clock. The RGB524 does not have this input.  
On the RGB525 bit 4 of the PLL Control 1 register selects the reference source of the PLL, REFCLK or EXTCLK. On the RGB524 this bit is reserved.  
Bits 7 - 6 of the Miscellaneous Control 2 register select the source of the pixel clock. On the RGB525 a setting of '10' will select EXTCLK. On the RGB524 this setting selects REFCLK.
14. The RGB525 pixel clock generator resets to the "off" condition and must be programmed before it is enabled. This allows a wide range of incoming REFCLK frequencies.  
The RGB524 pixel clock generator is the same, but the new SYSCLK PLL powers up enabled, with default programming values. REFCLK is shared between the two PLLs. This may restrict the REFCLK frequency, depending on how the generated SYSCLK is used at reset time.
15. System Clock Control (index 0x0008), System PLL Reference Divider (index 0x0015), and System PLL VCO Divider (index 0x0016) registers are added for controlling and programming the SYSCLK PLL.
16. The Miscellaneous Clock Control register has a bit added, SCLK INVT, that inverts the out-going SCLK. This is intended as an aid for meeting tight timings at the card level.
17. Two external frequency selects FS[3], FS[2] are eliminated. This restricts the external pixel frequency selection to four sets of values. Using internal selection, 16 values (direct programming) or 8 values (M/N programming) can still be chosen, the same as for the RGB525.
18. The ID register is changed to a value of "0x02".
19. In the Miscellaneous Control 3 register, the SWAP WORD bit is deleted. This RGB525 feature is not available on the RGB524.
20. The RGB525 pixel PLL requires two external resistors RPLLI and REXT. The two PLLs on the RGB524 do not require these resistors. Each PLL still requires external loop filter components.
21. The RGB525 TESTMODE input is TESTMODE on the RGB524. TESTMODE now has an internal pull-down resistor, so it may be left unconnected at the card level.

## C.0 Switching Into VGA Mode

The RGB524 has two fundamental modes of operation which depend on the input pixel port selected, VGA or VRAM. The port is selected with the "PORT SEL" bit (bit 0) of Miscellaneous Control 2 register.

On the RGB513, RGB514, and RGB525 products, there are two problems that can occur when switching from the VRAM port back to the VGA port. Internally latched data from the previously selected VRAM port can corrupt the VGA data, and the SCLK can stop running momentarily. Both of these problems can be circumvented with a software work-around.

For software compatibility with the RGB513, RGB514, and RGB525 it is recommended that this software work-around also be incorporated in the software used with the RGB524. The RGB524 does not require this software modification, but it does continue to operate correctly (that is, the software patch is transparent to the RGB524.)

The software modification is as follows:

When doing a "mode switch" into VGA mode, the following additional steps should be taken:

1. Set bits 1 and 0 to '1's in VRAM Mask Low register, to mask off the lowest VRAM byte. The remaining VRAM Mask bits are "don't care".
2. Set bit 6 (VMSK CNTL) in Miscellaneous Control 1 register to '1', to enable the VRAM MASKing.
3. Make sure at least one SCLK occurs. This means setting up the chip for VRAM pixel data operation. In particular, make sure that the Pixel Format register is set to one of the valid formats (4 BPP...32 BPP). A valid pixel format must be set or SCLK will not run.
4. At this point the low byte of the internal VRAM pixel data should be '0's, and will not interfere with the VGA data.

The VGA Port can now be selected. A two step process is required:

1. Write to the Miscellaneous Control 2 register. Set bit 0 (PORT SEL) to '0' for VGA, but write bits 7 and 6 as '01' (PCLK SEL = Internal PLL.)
2. Do a second write to the Miscellaneous Control 2 register. Again, set bit 0 (PORT SEL) to '0' for VGA. But now set bits 7 and 6 to '00' (PCLK SEL = LCLK.) The VGA port is now selected.

When doing a mode switch back to VRAM port operation, make sure that bit 6 (VMSK CNTL) in Miscellaneous Control 1 register is set back to '0', to disable the VRAM MASKing.

## D.0 -A Revision Level

The original RGB524 silicon has a bug: SCLK INVT (Miscellaneous Clock Control register Index 0x0002, bit 4) does not function correctly. A Product Alert, "RGB524/RGB528 SCLK INVERSION" (Document number IOGPAL001) was released which describes this problem. The Product Alert recommends replicating this function with on-card logic.

This silicon has been replaced with a revision that has the following changes:

1. The SCLK INVT function operates correctly.
2. The value in the Revision Level register (index 0x0000) is changed.
3. The part number is changed.

The following table summarizes these changes:

Part Number	SCLK INVT	Revision Level
IBM37-RGB524-CF-17C IBM37-RGB524-CF-22C	NON-FUNCTIONAL	0xf0
IBM37-RGB524-CF-17C-A IBM37-RGB524-CF-22C-A	FUNCTIONAL	0xe0
