## Description

IBM13T8644NPA is a 144-pin Synchronous DRAM Small Outline Dual In-line Memory Module (SO DIMM) which is organized as a 8Mx64 high-speed memory array. The SO DIMM uses four 8Mx16 SDRAMs in 400mil TSOP II packages and achieves high speed data transfer rates of up to 100MHz by employing a prefetch/pipeline hybrid architecture that supports the JEDEC 1N rule while allowing very low burst power. The SO DIMM is intended to comply with all JEDEC and INTEL PC100 rev 1.0 standards set for 144 pin SDRAM SO DIMMs.

All control, address, and data input/output circuits are synchronized with the positive edge of the externally supplied clock inputs. All inputs are sampled at the positive edge of the externally supplied clock (CK0). Internal operating modes are defined by combinations of the RAS, CAS, WE, S0, DQMB,

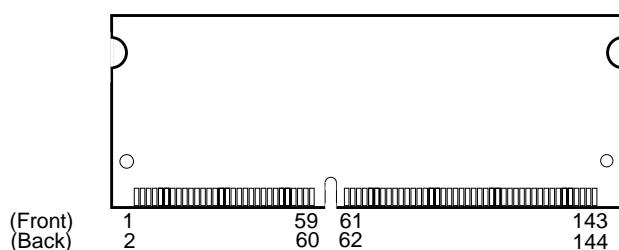

and CKE0 signals. A command decoder initiates the necessary timings for each operation. A 12 bit address bus accepts address information in a row/column multiplexing arrangement.

Prior to any access operation, the CAS latency, burst type, burst length, and burst operation type must be programmed into the SO DIMM by address inputs A0-A9 during the mode register set cycle.

The SO DIMM uses serial presence detects implemented via a serial EEPROM using the two pin IIC protocol. The first 128 bytes of serial PD data are used by the DIMM manufacturer. The last 128 bytes are available to the customer.

All IBM 144-pin SO DIMMs provide a high performance, flexible 8-byte interface in a 2.66" long space-saving footprint.

## Input/Output Functional Description

Symbol	Type	Signal	Polarity	Function
CK0	Input	Pulse	Positive Edge	The system clock input. All of the SDRAM inputs are sampled on the rising edge of their associated clock.
CKE0	Input	Level	Active High	Activates the CK0 signal when high and deactivates it when low. By deactivating the clock, CKE0 low initiates the Power Down mode, Suspend mode, or the Self Refresh mode.
S0	Input	Pulse	Active Low	Enables the associated SDRAM command decoder when low and disables the command decoder when high. When the command decoder is disabled, new commands are ignored but previous operations continue.
$\overline{\text{RAS}}$ , $\overline{\text{CAS}}$ , $\overline{\text{WE}}$	Input	Pulse	Active Low	When sampled at the positive rising edge of the clock, $\overline{\text{CAS}}$ , $\overline{\text{RAS}}$ , and $\overline{\text{WE}}$ define the operation to be executed by the SDRAM.
BA0, BA1	Input	Level	—	Selects which SDRAM bank is to be active.
A0 - A9, A11, A10/AP	Input	Level	—	During a Bank Activate command cycle, A0-A11 defines the row address (RA0-RA11) when sampled at the rising clock edge. During a Read or Write command cycle, A0-A8 defines the column address (CA0-CA8) when sampled at the rising clock edge. In addition to the column address, AP is used to invoke autoprecharge operation at the end of the burst read or write cycle. If AP is high, autoprecharge is selected and BA0 defines the bank to be precharged (low=bank A, high=bank B). If AP is low, autoprecharge is disabled. During a Precharge command cycle, AP is used in conjunction with BA0 to control which bank(s) to precharge. If AP is high, both bank A and bank B will be precharged regardless of the state of BA0. If AP is low, then BA0 is used to define which bank to precharge.
DQ0 - DQ63	Input Output	Level	—	Data Input/Output pins operate in the same manner as on conventional DRAMs.
DQMB0 - DQMB7	Input	Pulse	Active High	The Data Input/Output mask places the DQ buffers in a high impedance state when sampled high. In Read mode, DQM has a latency of two clock cycles and controls the output buffers like an output enable. In Write mode, DQM has a latency of zero and operates as a byte mask by allowing input data to be written if it is low but blocks the write operation if DQM is high.
SDA	Input Output	Level	—	Serial Data. Bidirectional signal used to transfer data into and out of the Serial Presence Detect EEPROM. Since the SDA signal is Open Drain/Open Collector at the EEPROM, a pull-up resistor is required on the system board.
SCL	Input	Pulse	—	Serial Clock. Used to clock all Serial Presence Detect data into and out of the EEPROM. Since the SCL signal is inactive in the "high" state, a pull-up resistor is recommended on the system board.
V <sub>DD</sub> , V <sub>SS</sub>	Supply			Power and ground for the module.

$t_{WR}$	Write Cycle Time		15	ms	1

- The Write cycle time ( $t_{WR}$ ) is the time from a valid stop condition of a write sequence to the end of the internal Erase/Program cycle. During the Write cycle, the bus interface circuits are disabled, SDA is allowed to remain high per the bus-level pull-up resistor, and the device does not respond to its slave address.

## Functional Description and Timing Diagrams

Refer to the IBM 128Mb Synchronous DRAM data sheet, document 33L8019, for the functional description and timing diagrams for SDRAM operation.

Refer to the IBM Application Notes: *Serial Presence Detect on Memory DIMMs* and *SDRAM Presence Detect Definitions* for the Serial Presence Detect functional description and timings.

All AC timing information refers to the timings at the SDRAM devices.
