

# CA82C59A

# PROGRAMMABLE INTERRUPT CONTROLLER

- Pin and functional compatibility with the industry standard 8259/8259A
- Fully static, high speed design (10 & 8 MHz)
- Compatible with 8080/85, 8086/88, 80286/386 and 68000 family microprocessor systems
- TTL input/output compatibility
- · Low power CMOS implementation
- · Eight level priority controller
- · Expandable to 64 levels
- Programmable interrupt modes, with each interrupt maskable
- · Edge- or level-triggered interrupt request inputs
- Polling operation

The Tundra CA82C59A is a high performance, completely programmable interrupt controller. It can process eight interrupt request inputs, assigning a priority level to each one, and is cascadable up to 64 interrupt requests. Individual interrupting sources are maskable. Its two modes of operation (Call and Vector) allow it to be used with virtually all 8000 and 80000 type processors, as well as with the 68000 family of microprocessors.

Featuring fully static, very high speed operation, the CA82C59A is designed to relieve the system CPU from polling in a multi-level priority interrupt system.

Table 2-1: Pin Descriptions

Symbol	Pi	ns	Туре	Name and Function
Symbol	PLCC	PDIP	type	Name and Function
A <sub>0</sub>	27	27	I	It is used by the CA82C59A to decipher various command words written by the CPU, and Status information read by the CPU. It is typically connected to the CPU - $A_0$ address line.
CAS <sub>0-2</sub>	12, 13, 15	12, 13, 15	I/O	Cascade Line: These signals are outputs for the master CA82C59A, and inputs for slaved CA82C59As. The CAS lines are used as a private bus by a CA82C59A master to control a multiple CA82C59A system structure.
CS	1	1	I	Chip Select: An active LOW signal used to enable $\overline{RD}$ and $\overline{WR}$ communication between the CPU and the CA82C59A. Note that $\overline{INTA}$ functions are independent of $\overline{CS}$ .
D <sub>7</sub> - D <sub>0</sub>	4 - 11	4 - 11 4 - 11 I/O		Data Bus: Bi-directional, tri-state, 8-bit data bus for the transfer of control, status and interrupt vector information.
INT	17	17	0	Interrupt: This signal goes HIGH when a valid interrupt request is asserted. It is used to interrupt the CPU, and is thus connected to the CPU interrupt pin.
ĪNTA	26	26	I	Interrupt Acknowledge: Signal used to enable the CA82C59A interrupt vector data onto the data bus by a sequence of interrupt acknowledge pulses issued by the CPU.
IR <sub>0-7</sub>	18 - 25	18 - 25	I	Interrupt Requests: Asynchronous input signals, an interrupt request is executed by raising an IR input (LOW to HIGH), and holding it HIGH until it is acknowledged (Edge Triggered Mode), or just by a HIGH level on an IR input (Level Triggered Mode).
RD	3	3	I	Read: Active LOW signal used to enable the CA82C59A to output status information onto the data bus for the CPU, when CS is LOW.
SP/EN	16	16	I/O	Slave Program/Enable Buffer: Active LOW, dual function control signal. When in the Buffered Mode, it can be used as an output to control buffer transceivers (EN). When not in the buffered mode it can be used as an input to designate a master (SP = 1) or a slave (SP = 0).
V <sub>DD</sub>	28	28	-	Power: 5 v ± 10% DC Supply
V <sub>SS</sub>	14	14	-	Ground: 0 v
WR	2	2	I	Write: Active LOW signal used to enable the CA82C59A to accept command words from the CPU, when CS is LOW.

#### **FUNCTIONAL DESCRIPTION**

The CA82C59A Programmable Interrupt Controller is designed for use in interrupt driven micro-computer systems. Acting as an overall peripherals manager, its functions include:

- Accepting interrupt requests from assorted peripheral devices
- · Determining which is the highest priority
- Establishing whether or not the new interrupt is of a higher priority than any interrupts which might be currently being serviced, and if so,
- · Issuing an interrupt to the CPU
- Then providing the CPU with the interrupt service routine address of the interrupting peripheral

Each peripheral device usually has a specific interrupt service routine which is particular to its operational or functional requirements within the system. The CA82C59A can be programmed to hold a pointer to the service routine addresses associated with each of the peripheral devices under its control. Thus when a peripheral interrupt is passed through to the CPU, the CA82C59A can set the CPU Program Counter to the interrupt service routine required. These pointers (or vectors) are addresses in a vector table.

The CA82C59A is intended to run in one of two major operational modes, according the type of CPU being used in the system. The CALL Mode is used for 8085 type microprocessor systems, while the VECTOR Mode is reserved for those systems using more sophisticated processors such as the 8088/86, 80286/386 or 68000 family.

In either mode, the CA82C59A can manage up to eight interrupt request levels individually, with a maximum capability of up to 64 interrupt request levels when cascaded with other CA82C59As. A selection of priority modes is also available such that interrupt requests can be processed in a number of different ways to meet the requirements of a variety of system configurations.

Priority modes can be changed or reconfigured dynamically at any time during system operation using the operation command words (OCWs), allowing the overall interrupt structure to be defined for a complete system. Note that the CA82C59A is programmed by the system software as an

I/O peripheral.

The major functional components of the CA82C59A are laid out in the block diagram of Figure 2-3. Vector data and device programming information are transferred from the system bus to the CA82C59A via the 3-state, bi-directional Data Bus Buffer which is connected to the internal bus of the controller. Control data between the CA82C59A and the CPU, and between master and slave CA82C59A devices, is managed by one of three functional blocks:

- The Read/Write Control block processes CPU initiated reads and writes to the CA82C59A registers
- The Control Logic block receives and generates the signals that control the sequence of events during an interrupt
- The Cascade Control block is used to operate a private bus (CAS<sub>0</sub> - CAS<sub>2</sub>) connecting master and slave CA82C59As in those systems having cascaded CA82C59As.

Programming data passed over the system bus is saved in the Initialization and Command Word Registers. Note that the contents of these registers cannot be read back by the CPU.

Peripheral interrupt requests (IR<sub>0</sub> - IR<sub>7</sub>) are handled by the functional blocks comprising the Interrupt Request Register (IRR), the Interrupt Mask Register (IMR), the In-Service Register (ISR) and the Priority Decision Logic block. Interrupt requests are received at the IRR, the IMR masks those interrupts which cannot be accepted by the CA82C59A, and the ISR shows those interrupt requests which are currently being processed. These three registers can all be read by the CPU under software control. The Priority Decision Logic block determines which interrupt will be processed next according to a variety of indicators which include the current priority, mode status, current interrupt mask and interrupt service status.

The actual operation of the CA82C59A and its many modes are described in the section following device specifications and characteristics.

These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

# **OPERATIONAL DESCRIPTION**

The CA82C59A is designed to operate in one of two mutually exclusive modes, selected according to the type of system processor used; Call Mode for 8080/85 type processors, and Vector Mode for 8088/86 and 80286/386 type processors. The major difference between these two modes is the way in which interrupt service routine address data is passed to the system CPU. Unless specifically programmed to the contrary, the CA82C59A defaults to the CALL Mode of operation, (see section on Programming).

#### Call Mode

In CALL mode, the interrupt service routine address is passed in two steps, (first the lower byte of the address, followed by the upper byte), in response to three Interrupt Acknowledge (INTA) signals sent by the CPU to the CA82C59A. In a system containing a single Interrupt Controller, the sequence of steps to respond to a peripheral interrupt request is outlined below, and shown graphically in Figure 2-7. The interrupt service routine addresses are loaded into the CA82C59A during the initialization procedures.

# Step

# **Event Sequence**

- One or more interrupt request lines (IR<sub>0</sub> IR<sub>7</sub>) are raised HIGH, setting corresponding IRR bits.
- The requests are evaluated by the CA82C59A, and
  if their priority is high enough, or if they are not
  masked, an INT signal is sent to the CPU.
- The CPU acknowledges the INT with an interrupt acknowledge (INTA).
- 6) On receipt of the INTA, the CA82C59A sets the highest priority ISR bit, and resets the corresponding IRR bit. In addition, the CA82C59A sends a CALL instruction (0CDH) to the CPU via the data bus.
- The CALL instruction causes the CPU to send two more INTA signals to the CA82C59A.
- 8) On receipt of the first of these two INTA signals, the CA82C59A sends the low order 8-bit address byte to the CPU via the data bus. On receipt of the second INTA, the high order address byte is sent to the CPU.
- 9) This completes the 3-byte CALL instruction procedure. The ISR bit is reset at the end of the interrupt sequence except in the Automatic EOI mode, where the ISR bit is reset automatically at the end of the third INTA.

#### **Vector Mode**

In VECTOR mode, the interrupt service routine address is calculated by the CPU from a one byte interrupt vector supplied by the CA82C59A. The significant bits T<sub>7-3</sub> of the interrupt vectors are loaded into the CA82C59A during the initialization procedures.

Note that no data is transferred by the CA82C59A to the CPU after the first  $\overline{\text{INTA}}$  signal (the CA82C59A data bus buffers are disabled). It is similar to the CALL mode in that this cycle is used for internal operations that freeze the state of the interrupts for priority resolution or, in cascaded mode; to issue the interrupt code on the cascade lines (CAS<sub>0-2</sub>) at the end of this cycle.

The sequence of steps that occur to respond to a peripheral interrupt request in Vector mode are outlined below and illustrated in Figure 2-10.

# Step

#### **Event Sequence**

- One or more interrupt request lines (IR<sub>0</sub> IR<sub>7</sub>) are raised HIGH, setting corresponding IRR bits.
- The requests are evaluated by the CA82C59A, and
  if their priority is high enough, or if they are not
  masked, an INT signal is sent to the CPU.
- The CPU acknowledges the INT with an interrupt acknowledge (INTA).
- 4) After receipt of the first INTA signal from the CPU, the CA82C59A sets the highest priority ISR bit and resets the corresponding IRR bit. The CA82C59A data bus buffer is not active during this cycle (high impedance state).
- Following receipt of the second INTA signal generated by the CPU, the CA82C59A sends an 8bit interrupt vector to the CPU via the data bus.
- This completes the 1-byte VECTOR mode procedure. In the Automatic End-of-Interrupt (AEOI) mode, the ISR bit is reset at the end of the second INTA.

In other EOI modes the ISR bit remains set until an appropriate EOI command is received after the end of the interrupt sequence.

The interrupt sequence procedures when several CA82C59As are cascaded together is shown for both CALL and VECTOR modes in Figure 2-9 and in Figure 2-12 respectively.

# **REGISTERS**

The CA82C59A contains a number of registers, used to keep track of interrupts which are being serviced, or pending, as well as those which are masked. These registers are described in Table 2-7. They can be written to using the command word

structure, or in the case of IRR, are set by external peripheral devices requesting interrupt service. The contents of all registers can be read by the CPU for status updates (see Table 2-8).

Table 2-7: CA82C59A Registers

Symbol	Name	Function
IMR	Interrupt Mask Register	An 8 - bit wide register that contains the interrupt request lines which are masked.
IRR	Interrupt Request Register	An 8 - bit wide register that contains the levels requesting an interrupt to be acknowledged. The highest request level is RESET from the IRR when an interrupt is acknowledged, (not affected by IMR).
ISR	In-Service Register	An 8 - bit wide register that contains the priority levels which are currently being serviced. The ISR is updated when an End of Interrupt Command (EOI) is received.

Table 2-8: Register Read/Write Operations

#### **PROGRAMMING**

The CA82C59A is initialized and programmed with special command words issued by the CPU. These commands fall into two major categories: Initialization Command Words ( $ICW_1 - ICW_4$ ), and Operational Command Words

(OCW<sub>1</sub> - OCW<sub>3</sub>). Initialization commands are used to bring the CA82C59A to a known state when the system is first activated, or after a system restart.

Operational commands are used once the CA82C59A is in operation (and after it has been initialized), to set, or alter specific interrupt program modes. The format and use of these two command types is described below.

#### **Initialization Commands**

The CA82C59A is initialized by a sequence of 2 to 4 command words (ICWs), where the actual number of commands sent depends on the system configuration, and the initial operating modes to be programmed. Note that each CA82C59A in the system must be initialized before operations begin in earnest (Figure 2-14).

The initialization sequence is started when the CPU sends  $A_0 = 0$  and  $ICW_1$  with  $D_4 = 1$  (Figure 2-13). During initialization, the events below occur automatically:

- Edge sense circuit is reset. Thus, after initialization, an interrupt request must make a LOW-to-HIGH transition to be recognized.
- IMR is cleared.
- The priority of IR<sub>7</sub> is set to 7 (the lowest priority).
- · Special Mask Mode is reset.
- · Status read is set to IRR.
- If SNGL bit of ICW<sub>1</sub> = 1, then ICW<sub>3</sub> must be programmed.
- If IC<sub>4</sub> bit of ICW<sub>1</sub> = 0, then functions selected in ICW<sub>4</sub>
  are reset: Non-buffered Mode, no Automatic EOI, Call
  Mode operation.
- If IC<sub>4</sub> = 1, then CA82C59A will expect ICW<sub>4</sub>.

# Bit Definitions (ICW<sub>1</sub>, ICW<sub>2</sub>)

IC<sub>4</sub> Set if ICW<sub>4</sub> is to be issued. This bit must be set for systems operating in Vector Mode.

SNGL Set if this CA82C59A is not cascaded to other CA82C59As in the system (ICW<sub>3</sub> not issued). When CA82C59As are cascaded, SNGL is reset and ICW<sub>3</sub> is issued.

ADI CALL Address Interval. If ADI = 1, then interval = 4. If ADI = 0, then interval = 8.

LTIM Level Trigger Mode. If LTIM = 1, edge detect logic on the IR inputs is disabled, and the CA82C59A operates in level triggered mode.

A<sub>5-15</sub> Service routine Page Starting Address (Call Mode). In a single CA82C59A system, the 8 interrupt request levels generate CALLs to 8 equally spaced locations in memory. These are spaced at intervals of either 4 or 8 memory locations according to the ADI value. Thus, the service routines associated with each CA82C59A in the system occupy pages of 32 or 64 bytes respectively.

Bits  $A_0$  -  $A_4$  are automatically inserted to give an address length of 2 bytes ( $A_0$  -  $A_{15}$ ). Note that the 8-byte interval is compatible with CA80C85B restart instructions.

 $A_{11-15}$  Service routine Vector Address Byte. In the vector mode, bits  $A_{11}$  -  $A_{15}$  are inserted in the five most significant places of the vector byte.

The three least significant bits are inserted by the CA82C59A according to the interrupt request level. The ADI and A<sub>5</sub> - A<sub>10</sub> bits are ignored.

■ 6588101 0004093 T43 **■** 

# Bit Definitions (ICW<sub>3</sub>)

This word is used only when SNGL = 0 in ICW<sub>1</sub>, at which time the contents then depend on whether it is being sent to a master CA82C59A, or a slave device.

Master Mode

Sent to the master CA82C59A, each bit of  $ICW_3$  represents a potential slave device connected to an IR input. If a slave exists, the corresponding bit in  $ICW_3$  is set. Where a slave is not attached to an IR input of the master, the corresponding bit is reset. In operation, the master outputs byte 1 of the interrupt sequence to the bus, then enables the appropriate slave (via the cascade bus  $CAS_{0-2}$ ) to output bytes 2 and 3 (Call Mode) or byte 2 only (Vector Mode).

Slave Mode

When sent to a slave CA82C59A, bits  $\rm ID_{0.}$  contain the slave address on the cascade bus. Each slave device in the system must be initialized with a unique address. Remaining bits are not used.

In operation, the slave compares the cascade input to its 3-bit address and if they match, outputs byte 2 and 3 (Call Mode), or byte 2 only (Vector Mode) to the bus.

# Bit Definitions (ICW<sub>4</sub>)

This word is used only when bit  $IC_4$  in  $ICW_1$  is set. Note that only five bits are used.

μPM Mic

Microprocessor System Mode:  $\mu PM = 0$  for

Call Mode,  $\mu$ PM = 1 for Vector Mode.

AEOI This bit is set if the Automatic End of Interrupt

Mode is to be programmed.

M/S When Buffered Mode is selected, the M/S bit is

used to determine the master/slave programming. That is, M/S = 1 indicates the device is a master, while M/S = 0 indicates a slave. If the

BUF bit is not set, M/S is not used.

BUF Buffered Mode is programmed by setting

BUF = 1. In buffered mode, the output pin SP/EN becomes an enable output, and the M/S bit determines whether the device is a master or

a slave.

SFNM Special Fully Nested Mode is programmed by

setting SFNM = 1.

Figure 2-13: Initialization Flow Chart

# **Operational Commands**

Once the CA82C59A has been initialized, it can accept and process interrupt requests received on its IR input lines. Interrupts are processed according to the modes programmed during the initialization process. A number of commands, sent to the CA82C59A from the CPU, allow the programmed modes or the interrupt request priorities to be changed on the fly during operation. These commands are described in the following sections (and in Figure 2-15).

# Bit Definitions (OCW<sub>1</sub>)

 $OCW_I$  is used to set and clear mask bits in the IMR, thus enabling or disabling specific IR inputs. In the Special Mask Mode, the ISR is also masked.

 $\begin{array}{ll} M_{0\text{--}7} & \text{Bits } M_{0\text{--}7} \text{ correspond to the 8 IR inputs. If bit} \\ M_n = 1, \text{ the } IR_n \text{ input is disabled.} \\ \text{If } M_n = 0, \text{ the } IR_n \text{ input is enabled.} \end{array}$ 

# Bit Definitions (OCW<sub>2</sub>)

OCW<sub>2</sub> is used to program the different End of Interrupt (EOI) Modes, and alter the interrupt request priorities.

 $L_{0-2}$  These bits designate the interrupt level to be acted upon when bit SL=1 (active).

EOI The End of Interrupt command is issued by the CPU, rather than by the CA82C59A (in automatic EOI mode). Note that this bit is used in conjunction with bits R and SL to control the interrupt priority assignments and rotations.

SL Set Interrupt Level bit. This lowest priority interrupt is assigned to the IR input corresponding to the octal value of  $L_{0.2}$ .

R This bit determines if interrupt priority rotation is in effect. R = 1 indicates priorities will be rotated, perhaps combined with other modes.

# Bit Definitions (OCW<sub>3</sub>)

**ESMM** 

OCW<sub>3</sub> is used to program the Special Mask Mode, the Polling Mode, and select internal registers to be read by the CPU.

RIS If RIS = 0, select ISR. If RIS = 1, select IRR.

RR Read Register bit. If RR = 1, output the contents of the register selected by bit RIS onto the bus. The register selection is retained, so OCW<sub>3</sub> does not have to be reissued in order to read the same register again.

P If P = 1, the Polling Mode is selected for this CA82C59A. In this mode the CPU will poll for new interrupt requests, rather than having the CA82C59A actively set the CPU INT input.

SMM If Special Mask Mode is enabled (ESMM = 1), then SMM = 1 programs the special mask mode, and SMM = 0 clears the special mask mode.

If ESMM = 1, then the special mask mode is enabled and can be set or reset by the SMM bit.

If ESMM = 0, the special mask mode is disabled and SMM is ignored.

# **OPERATIONAL MODES**

The CA82C59A can be programmed to operate in a number of different modes which are summarized and described below. Depending on the mode, some are set during initialization, and some during operation (with the command word structure).

Mode	Location Set
Buffer Mode	BUF, M/S (ICW <sub>4</sub> )
Cascaded Mode	SNGL (ICW <sub>1</sub> )
•Master Mode	(ICW <sub>3</sub> )
•Slave Mode	${\rm ID}_{0-2}\left({\rm ICW}_3\right)$
End of Interrupt (EOI) Modes	EOI (OCW <sub>2</sub> )
<ul> <li>Automatic EOI Mode</li> </ul>	AEOI (ICW <sub>4</sub> )
•Non-specific EOI	EOI, SL, R (OCW <sub>2</sub> )
•Specific EOI	EOI, SL, R (OCW <sub>2</sub> )
Nested Modes	
•Fully Nested Mode	default mode
•Special Fully Nested Mode	SFNM(ICW <sub>4</sub> )
	AEOI (ICW <sub>4</sub> )
Polling Mode	P (OCW <sub>3</sub> )
Rotation Modes	
•Automatic Rotation Mode	R, SL, EOI (OCW $_2$ )
•Specific Rotation Mode	$R, SL, L_{0-2} (OCW_2)$
Special Mask Mode	ESMM, SMM (OCW <sub>3</sub> )
System Modes	
•CALL Mode	μPM(ICW <sub>4</sub> )
<ul> <li>VECTOR Mode</li> </ul>	μPM (ICW <sub>4</sub> )
	IC4 (ICW <sub>1</sub> )
Trigger Modes	
•Edge Triggered Mode	LTIM (ICW <sub>1</sub> )
<ul> <li>Level Triggered Mode</li> </ul>	LTIM (ICW <sub>1</sub> )

#### **Buffer Mode**

In larger systems the CA82C59A may be required to drive the data bus through a buffer. To handle this situation, the Buffer Mode is programmed during initialization (using the BUF and M/S bits in  $ICW_4$ ).

When in buffer mode,  $\overline{\text{SP/EN}}$  is used to enable the data bus buffers, and determine the direction of data flow through the buffer (Figure 2-16). This signal is active when the output ports of the CA82C59A are activated.

Figure 2-16: Buffer Mode

Note that when cascaded CA82C59As are required to be used in the buffer mode, the master/slave selection is done using the M/S bit of ICW<sub>4</sub>, (and SNGL bit of ICW<sub>1</sub> is set to 1). M/S is set to 1 for the master mode, 0 for the slave mode.

#### **Cascaded Mode**

In systems that contain more than 8 priority interrupt levels, several CA82C59A devices can be easily cascaded together to handle a maximum of 64 interrupt levels. In a cascaded configuration, one CA82C59A serves as a master, controlling up to 8 slaves (able to handle 8 interrupts each). The master selects the slaves via the cascade local bus (CAS $_{0-2}$ ), enabling the corresponding slave to output the interrupt service routine address (or vector) following each of the second and third  $\overline{\text{INTA}}$  signals (second  $\overline{\text{INTA}}$  signal only in Vector mode). At the end of the interrupt cycle, the EOI command must be issued twice, one for the master, and one for the appropriate slave.

The CAS<sub>0-2</sub> bus lines are normally held in a LOW state, and activated only for slave inputs (non-slave inputs to the master do not affect the cascade bus). The slave address will be held on the cascade bus from the trailing edge of the first INTA signal to the trailing edge of the last INTA signal (either second or third depending on the system mode).

Within the system, each slave can be programmed to operate in a different mode (except AEOI), independently of other slave devices. The interrupt output (INT) of each slave is tied to one of the interrupt request lines (IR<sub>0-7</sub>) of the master device. Unused IR pins on the master device can be connected to other peripheral devices (as in the single stand-alone mode of operation), or left unconnected.

Note that an address decoder is required to activate the chip select  $\overline{(CS)}$  input of each CA82C59A in the system.

2-146

**Tundra Semiconductor Corporation** 

**■ 6588101 0004098 525** ■

#### Master Mode

A CA82C59A operating in the Master Mode can be controlling both peripheral interrupts as well as other CA82C59A slave devices. Since both types of inputs are connected to the IR<sub>0-7</sub> pins, it is necessary to differentiate between the two. This is accomplished in the initialization control word (ICW<sub>3</sub>) sent out to the master. ICW<sub>3</sub> sets the S<sub>n</sub> bits corresponding to IR<sub>n</sub> pins connected to slaves equal to one (1), while Sm bits corresponding to IR<sub>m</sub> pins connected to peripheral inputs are reset to zero.

Peripheral interrupt requests to  $IR_m$  pins  $(S_m = 0)$  are handled by the master as if it were operating singly. That is, the CAS line remain LOW, and the master provides the interrupt or vector as required.

Slave interrupt requests to  $IR_n$  pins  $(S_n = 1)$  are handled as follows; the master sends an interrupt to the CPU if the slave requesting the interrupt has priority. If so, the master outputs the slave address n to the CAS bus on the first  $\overline{INTA}$  signal, then lets the slave complete the remainder of the interrupt cycle. Note again however, that two EOI commands are required to terminate the sequence, one each for the master and slave.

#### Slave Mode

When a slave CA82C59A receives a peripheral interrupt request, and it has no higher interrupt requests pending, the slave sends an interrupt request to the master via its INT output. This interrupt request is passed by the master to the CPU, which then initiates the interrupt cycle, in turn causing the master to output the slave's address on the CAS bus. Each slave in the system continuously monitors the CAS bus, comparing the addresses thereon until a match is found with its own address. When the slave initiating the interrupt request finds an address match, it completes the interrupt sequence as though it were a single CA82C59A.

Note: Since the master holds the CAS bus LOW (corresponding to CAS address 0) when processing peripheral interrupt requests, address 0 should not be used as a slave address unless the system contains the full complement of 8 slaves.

# End of Interrupt (EOI) Modes

The EOI Modes are used to terminate the request for interrupt service sequence, update the ISR register and alter the interrupt priorities. The EOI mode selected depends on the nesting mode currently programmed. The options are discussed in the sections following.

### Automatic EOI (AEOI) Mode

In AEOI Mode, the ISR bit corresponding to the interrupt is set and reset automatically during the final INTA signal. This means that the CPU does not have to issue an EOI command at the end of the interrupt routine.

Caution is urged in using AEOI however, as the ISR does not save the routine currently in service in this mode. Thus, unless the interrupts are disabled by the interrupt service routine, a stack overflow situation can result from newly generated interrupts (which bypass the priority structure), or from level triggered interrupts.

The Automatic EOI mode is programmed by setting the AEOI bit in  $ICW_4 = 1$ .

# Non-specific (Normal) EOI Mode

When the CA82C59A is operated in the Fully Nested Mode, it can easily determine which ISR bit is to be reset at the conclusion of an interrupt sequence. In this case, the non-specific EOI command is used to reset the highest priority level selected from the interrupts in service, (the valid assumption being that the last interrupt level acknowledged and serviced necessarily corresponds to the highest priority ISR bit set).

A Non-specific EOI Mode is selected via  $OCW_2$ , where EOI = 1, SL = 0 and R = 0). Refer to Figure 2-17.

a) Non-specific EOI Command

	D <sub>7</sub>	D <sub>6</sub>	$D_5$	$D_4$	$D_3$	$D_2$	D <sub>1</sub>	$D_0$
OCW <sub>2</sub>	0	0	1	0	0	х	x	х

b) Specific EOI Command

OCW <sub>2</sub>	0	1	1	0	0	L <sub>2</sub>	L <sub>1</sub>	Lo

c) Rotate on Non-specific EOI Command

OCW <sub>2</sub>	1	0	1	0	0	х	х	х

d) Rotate on Specific EOI Command

Figure 2-17: EOI Commands

**Tundra Semiconductor Corporation** 

2-147

# Specific EOI Mode

The Specific EOI Mode is required when the fully nested (normal) mode is not used, and the CA82C59A is unable to determine the last interrupt level acknowledged (such as might be encountered if the Special Mask Mode is programmed). The Specific EOI command identifies the ISR bit (interrupt level) to be reset using bits  $L_{0-2}$  of  $OCW_2$ , which also has the following bit settings: EOI = 1, SL = 1 and R = 0. Refer to Figure 2-17.

#### Mask Modes

The Mask Modes are used to selectively enable or disable interrupt requests. This is distinct from the automatic disabling of an interrupt which is in effect while a request from the same interrupt is being serviced.

#### **Normal Mask Mode**

Interrupt request lines  $IR_{0.7}$  can be individually masked in the Interrupt Mask Register (IMR), using  $OCW_1$ . Each bit in IMR masks one interrupt request line if it is set (= 1), with no effect on the other interrupt request lines. Bit 0 masks  $IR_0$ , bit 1 masks  $IR_1$  etc.

#### Special Mask Mode

The Special Mask Mode is used to dynamically alter the interrupt priority structure under software control during program execution. In this mode, when a mask bit is set in OCW1, it disables further interrupts at that level, and enables interrupts from all other levels that are not masked. This includes those interrupts which are lower (as well as higher) in priority.

The Special Mask Mode is set by ESMM = 1 and SMM = 1 in OCW<sub>3</sub>. To clear this mode, the CPU must issue another OCW<sub>3</sub> with ESMM = 1 and SMM = 0. Setting ESMM = 0 alone has no effect. To correctly enter the Special Mask Mode, use the following procedure:

- 1) CPU reads the ISR
- 2) CPU writes the ISR data from (1) to the IMR
- CPU selects Special Mask Mode by issuing OCW3 with ESMM = 1 and SMM = 1.

This procedure ensures that all interrupt requests not currently in service will be enabled.

Note that if IMR is not set equal to ISR when Special Mask Mode is selected, bits which may be set in the ISR will be ignored. If a corresponding bit is not set in IMR, that interrupt request may be serviced, causing all interrupts of lower priority to be effectively disabled. This is illustrated in Figure 2-18.

When the Special Mask Mode is selected, the Specific EOI Mode must be used to terminate the interrupt sequence, so the CPU can explicitly specify which ISR bit is to be reset.

#### **Nested Modes**

The nesting modes are used to determine, and change, the priority of incoming interrupt requests.

Interrupt requests  $\rm IR_6$  and  $\rm IR_7$  cannot be accepted when IMR  $\neq$  ISR, even with the Special Mask Mode set.

All interrupt requests, except those being serviced can be accepted when IMR = ISR, and the Special Mask Mode is set.

Priority Levels That Can Interrupt (White Boxes).

Figure 2-18: Special Mask Mode

# **Fully Nested Mode**

The default nesting mode, entered automatically after initialization, unless another mode has been programmed. In the Fully Nested Mode, the interrupt request priorities are set in descending order from 0 to 7. That is: IR<sub>0</sub> is the highest priority interrupt, IR<sub>7</sub> the lowest.

When an interrupt is acknowledged, the highest priority request is selected, the corresponding ISR bit is set, and the service routine address information is output to the data bus. The ISR bit is reset by the EOI command from the CPU, or auto-

2-148

**Tundra Semiconductor Corporation** 

🚾 6588101 0004100 TO3 🚾

matically if AEOI Mode is programmed, at the completion of the interrupt sequence. While the ISR bit is set, all interrupt requests of equal or lower priority are inhibited. Interrupt requests of higher priority will generate an interrupt to the CPU, but whether or not these will be acknowledged depends on the system software logic. Interrupt priorities can be altered in this mode using one of the Rotation Modes.

Note that fully nested interrupt priorities are not necessarily preserved in those systems containing cascaded CA82C59As, as it is possible for interrupts of higher priority than the one being serviced to be ignored. This situation occurs when a slave accepts a peripheral interrupt request (and passes the request to the master). When the master accepts the request, it locks out further interrupts from that slave. Should an interrupt of higher priority come in to the same slave, it will not be recognized until the interrupt being serviced has completed processing. To preserve interrupt priorities in this situation, use the Special Fully Nested Mode.

Interrupt request IR $_4$  can be accepted after IR $_2$  has been completely serviced. The HIGH level is maintained at IR $_4$  until IR $_4$  is accepted.

Figure 2-19: Fully Nested Mode

#### **Tundra Semiconductor Corporation**

# Special Fully Nested Mode

This mode is very similar to the Fully Nested Mode, but is used in systems with cascaded CA82C59s, so as to preserve the interrupt priorities within each slave, as well as within the master. The Special Fully Nested Mode is programmed by setting the SFNM bit in the ICW<sub>4</sub> word in both the master and the slave during initialization. This allows interrupt requests of a higher level than the one being serviced to be accepted by the master from the same slave. That is, the slave is not locked out from the priority logic in the master, and higher priority interrupts within the slave will be recognized by the master, which will generate an interrupt to the CPU.

Caution should be exercised in this mode during the End Of Interrupt processing. It is essential that the system software check whether or not the interrupt just serviced was the only one from that slave. After the first non-specific EOI has been issued to the slave, the CPU should read the slave's ISR and check that no other bits are set (ISR = 0). Only if the slave ISR is zero, should a non-specific EOI be sent to the master to complete the interrupt sequence. If bits are set in the slave ISR, no EOI should be sent to the master.

# **Polling Mode**

The Polling Mode is used to bypass the CA82C59A Interrupt control logic in favour of CPU software control over interrupt request processing. This allows systems to be built up with more than one master CA82C59A, and consequently, the system can contain more than 64 interrupt priority levels (since each master can handle 64 levels individually). In this case, the CPU polls each master looking for the highest priority interrupt request within the realm of each master.

#### NOTES:

- 1. Wo W2 is binary code of highest priority level requesting service.
- 2. INT is equal to one (1) if there is an interrupt.

Figure 2-20: Poll Command

2-149

In the Polling Mode, the INT outputs of the CA82C59A masters, and the INT input of the CPU are disabled. Interrupt service to individual peripheral devices is accomplished in system software by using the Poll Command (Bit 'P' = 1 in OCW<sub>3</sub>). When a poll command has been issued, the CA82C59A waits for the CPU to perform a register read. This read is treated by the CA82C59A as an interrupt acknowledge, and it sets the appropriate ISR bit and determines the priority level if there is an interrupt request pending. It then outputs the polling data byte onto the data bus (see Figure 2-20), including the binary code of the highest priority level requesting service. The CPU then processes the interrupt according to the polling data read, terminating the interrupt sequence with an EOI.

#### **Rotation Modes**

The different Rotation Modes allow the interrupt request priorities to be changed either automatically, or under software control. This is particularly useful for situations where there are a number of equal priority devices, or where a particular application may call for a specific priority change.

#### **Automatic Rotation Mode**

The Automatic Rotation Mode is recommended where there are a number of equal priority devices. In this mode the device is assigned the lowest priority immediately after it has had an interrupt request serviced. Its priority is subsequently increased as other devices have their interrupt requests serviced, and are then rotated to the bottom of the priority list. In the worst case, a device would have to wait for a maximum of seven other device interrupts of equal priority to be serviced once, before it was serviced. The effect of rotation on interrupt priority is illustrated in Figure 2-21.

Automatic Rotation can be activated in one of two ways, both using the command word OCW<sub>2</sub>, and both combined with EOI modes:

- Rotation in Non-specific EOI Mode (R = 1, SL = 0 and EOI = 1)
- Rotation in Automatic EOI Mode (R = 1, SL = 0 and EOI = 0). This mode must be cleared by the CPU (accomplished by sending OCW<sub>2</sub> with: R = 0, SL = 0 and EOI = 1.

# Specific Rotation Mode

The Specific Rotation Mode provides a mechanism to arbitrarily change interrupt priority assignments. This is accomplished by programming the lowest priority interrupt request line (specified by bits  $L_{0-2}$  in  $OCW_2$ ), thereby fixing the other priorities. That is, if  $IR_4$  is programmed as the lowest priority device, then  $IR_5$  will have the highest priority.

Caution: Because this change in priority levels is different from the normal Fully Nested Mode, it is essential that the user manage the interrupt nesting via the system software.

Specific rotation can be activated in one of two ways, both using the command word OCW<sub>2</sub>:

- The Set Priority command is issued in OCW<sub>2</sub> with: R = 1, SL = 1 and L<sub>0-2</sub> equal to the binary code of the lowest priority device.
- As part of the Specific EOI Mode, with OCW<sub>2</sub>, (Rotate on Specific EOI command) values: R = 1, SL = 1, EOI = 1 and L<sub>0-2</sub> equal to the binary priority level code of the lowest priority device. When the specific EOI is issued by the CPU, the CA82C59A resets the ISR bit designated by bits L<sub>0-2</sub> in OCW<sub>2</sub>, then rotates the priorities so that the interrupt just reset becomes the lowest priority.

**BEFORE ROTATE:** IR<sub>4</sub> is the highest priority requiring service. **AFTER ROTATE:** IR<sub>4</sub> was serviced, all other priorities have

been rotated correspondingly.

# System Modes

The CA82C59A must operate in the system mode that corresponds to the processor type used in the system. Call Mode is used for 8085 type systems (and features an interrupt cycle controlled by three INTA signals), while Vector Mode is used for more sophisticated 8088/86 and 80286/386 type systems (and features an interrupt cycle controlled by only two INTA signals). These modes are described in more detail back in the Operational Description section.

### **Trigger Modes**

In the CA82C59A, the interrupt request lines (IR $_{0.7}$ ) can be programmed for either edge or level triggering sensitivity, with the requirement that all IR lines must be in the same mode. That is, all edge triggered, or all level triggered. Figure 2-24 illustrates the priority cell diagram which shows a conceptual circuit of the level sensitive and edge sensitive input circuitry of the IR lines.

Note that to ensure a valid interrupt request is registered by the CA82C59A, it is essential that the IR input remain HIGH until after the first  $\overline{\text{INTA}}$  has been received. In both modes, if the IR input goes LOW before this time, the interrupt will be registered as a default IR<sub>7</sub> regardless of which IR input initiated the interrupt request. This default IR<sub>7</sub> can be used to detect (and subsequently ignore) spurious interrupt signals such as those caused by glitches or noise on the IR input lines. The technique is described below:

Figure 2-23: Trigger Mode Timing

- If the IR<sub>7</sub> input is not used, it can be assigned solely to intercepting spurious interrupt requests, invoking a simple service routine that contains a return only, thus effectively ignoring the interrupt.
- If IR<sub>7</sub> is used for a peripheral interrupt, a default IR<sub>7</sub> is detected with the extra step of reading the ISR. A normal IR<sub>7</sub> interrupt causes the corresponding bit to be set in the ISR, while a default IR<sub>7</sub> interrupt does not. It is necessary that the system software keep track of whether or not the IR<sub>7</sub> service routine has been entered. In the event that another IR<sub>7</sub> interrupt occurs before servicing is complete, it will be a default IR<sub>7</sub> interrupt (and should be ignored)

# **Edge Triggered Mode**

Programmed by setting the LTIM bit in ICW3: LTIM = 0 for low-to-high-transition edge triggering. An interrupt request is detected by a rising edge on an IR line. The IR line must remain HIGH until after the falling edge of the first  $\overline{\text{INTA}}$  signal has been received from the CPU. This is required to latch the corresponding IRR bit. It is recommended that the IR line be kept HIGH to help filter out noise spikes that might cause spurious interrupts. To send the next interrupt request, temporarily lower the IR line, then raise it.

# **Level Triggered Mode**

Programmed by setting the LTIM bit in  $ICW_3$ : LTIM = 1 for level triggering. An interrupt request is detected by a HIGH level on an IR line. This HIGH level must be maintained until the falling edge of the first  $\overline{INTA}$  signal (as in the edge-triggered mode), to ensure the appropriate IRR bit is set. However, in the level triggered mode, interrupts are requested as long as the IR line remains HIGH. Thus, care should be exercised so as to prevent a stack overflow condition in the CPU.
