- Available in SSOP, QSOP, and TSSOP packages

DESCRIPTION:

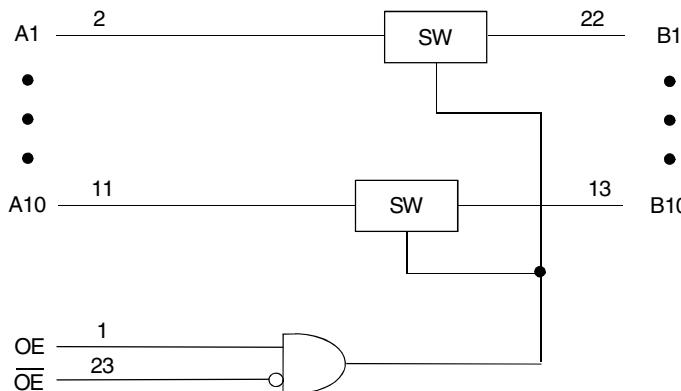

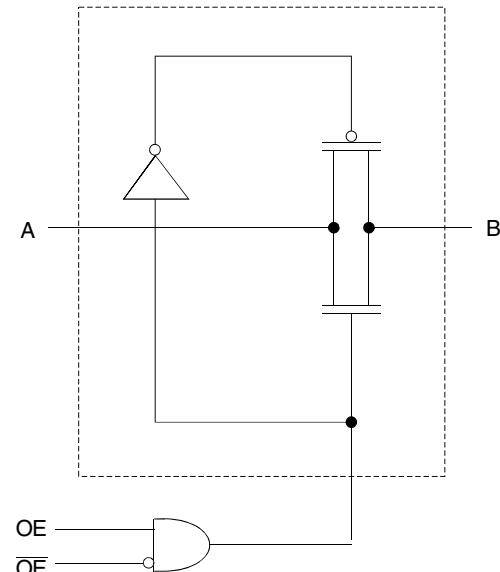

The CBTLV3862 provides ten bits of high-speed bus switching with low on-state resistance of the switch allowing connections to be made with minimal propagation delay.

The device is organized as one 10-bit bus switch. The switches are controlled by independent active-low enable (\overline{OE}) and active-high enable (OE) controls.

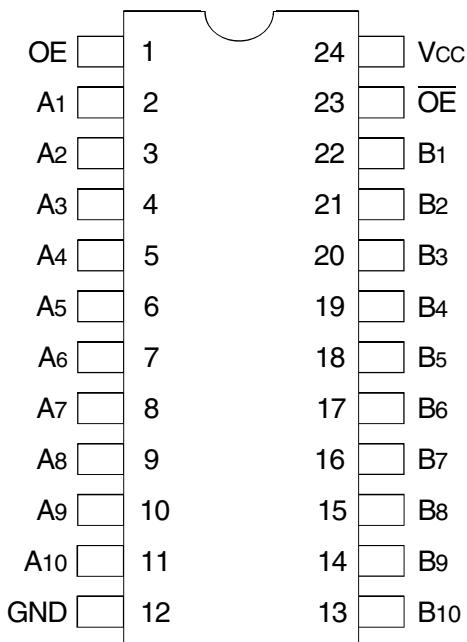

To ensure the high-impedance state during power up or power down, \overline{OE} should be tied to V_{CC} through a pullup resistor; the minimum value of the resistor is determined by the current-sinking capability of the driver, and OE should be tied to GND.

APPLICATIONS:

- 3.3V High Speed Bus Switching and Bus Isolation

NOTES:

1. Typical Values are at $V_{CC} = 3.3\text{V}$, $+25^\circ\text{C}$ ambient.
2. The increase in supply current is attributable to each input that is at the specified voltage level rather than V_{CC} or GND.
3. This is measured by the voltage drop between the A and B terminals at the indicated current through the switch.
