

## LH28F008SC-V 8-MBIT (1 MB x 8) SmartVoltage Flash MEMORY

- **SmartVoltage Technology**
  - 5V  $V_{CC}$
  - 5V or 12V  $V_{PP}$
- **High-Performance**
  - 85 ns Read Access Time
- **Enhanced Automated Suspend Options**
  - Byte Write Suspend to Read
  - Block Erase Suspend to Byte Write
  - Block Erase Suspend to Read
- **Enhanced Data Protection Features**
  - Absolute Protection with  $V_{PP}=GND$
  - Flexible Block Locking
  - Block Erase/Byte Write Lockout during Power Transitions
- **Industry-Standard Packaging**
  - 40-Lead TSOP, 44-Lead PSOP
- **Chip Size Packaging**
  - 42-Lead CSP
- **SRAM-Compatible Write Interface**
- **High-Density Symmetrically-Blocked Architecture**
  - Sixteen 64-Kbyte Erasable Blocks
- **Extended Cycling Capability**
  - 100,000 Block Erase Cycles
  - 1.6 Million Block Erase Cycles/Chip
- **Low Power Management**
  - Deep Power-Down Mode
  - Automatic Power Savings Mode  
Decreases  $I_{CC}$  in Static Mode
- **Automated Byte Write and Block Erase**
  - Command User Interface
  - Status Register
- **ETOX™ V Nonvolatile Flash Technology**
- **Not designed or rated as radiation hardened**

SHARP's LH28F008SC-V Flash memory with SmartVoltage technology is a high-density, low-cost, nonvolatile, read/write storage solution for a wide range of applications. Its symmetrically-blocked architecture, flexible voltage and extended cycling provide for highly flexible component suitable for resident flash arrays, SIMMs and memory cards. Its enhanced suspend capabilities provide for an ideal solution for code + data storage applications. For secure code storage applications, such as networking, where code is either directly executed out of flash or downloaded to DRAM, the LH28F008SC-V offers three levels of protection: absolute protection with  $V_{PP}$  at GND, selective hardware block locking, or flexible software block locking. These alternatives give designers ultimate control of their code security needs.

The LH28F008SC-V is manufactured on SHARP's 0.4 $\mu$ m ETOX™ V process technology. It comes in industry-standard packages: the 40-lead TSOP and 42-Lead CSP, ideal for board constrained applications, and the rugged 44-lead PSOP. Based on the 28F008SA architecture, the LH28F008SC-V enables quick and easy upgrades for designs demanding the state-of-the-art.

\*ETOX is a trademark of Intel Corporation.

- Handle this document carefully for it contains material protected by international copyright law. Any reproduction, full or in part, of this material is prohibited without the express written permission of the company.
- When using the products covered herein, please observe the conditions written herein and the precautions outlined in the following paragraphs. In no event shall the company be liable for any damages resulting from failure to strictly adhere to these conditions and precautions.
  - (1) The products covered herein are designed and manufactured for the following application areas. When using the products covered herein for the equipment listed in Paragraph (2), even for the following application areas, be sure to observe the precautions given in Paragraph (2). Never use the products for the equipment listed in Paragraph (3):
    - Office electronics
    - Instrumentation and measuring equipment
    - Machine tools
    - Audiovisual equipment
    - Home appliance
    - Communication equipment other than for trunk lines
  - (2) Those contemplating using the products covered herein for the following equipment which demands high reliability, should first contact a sales representative of the company and then accept responsibility for incorporating into the design fail-safe operation, redundancy, and other appropriate measures for ensuring reliability and safety of the equipment and the overall system.
    - Control and safety devices for airplanes, trains, automobiles, and other transportation equipment
    - Mainframe computers
    - Traffic control systems
    - Gas leak detectors and automatic cutoff devices
    - Rescue and security equipment
    - Other safety devices and safety equipment, etc.
  - (3) Do not use the products covered herein for the following equipment which demands extremely high performance in terms of functionality, reliability, or accuracy.
    - Aerospace equipment
    - Communications equipment for trunk lines
    - Control equipment for the nuclear power industry
    - Medical equipment related to life support, etc.
  - (4) Please direct all queries and comments regarding the interpretation of the above three Paragraphs to a sales representative of the company.
- Please direct all queries regarding the products covered herein to a sales representative of the company.

### 1 INTRODUCTION

This datasheet contains LH28F008SC-V specifications. Section 1 provides a flash memory overview. Sections 2, 3, 4, and 5 describe the memory organization and functionality. Section 6 covers electrical specifications. LH28F008SC-V Flash memory documentation also includes application notes and design tools which are referenced in Section 7.

#### 1.1 New Features

The LH28F008SC-V SmartVoltage Flash memory maintains backwards-compatibility with SHARP's 28F008SA. Key enhancements over the 28F008SA include:

- SmartVoltage Technology
- Enhanced Suspend Capabilities
- In-System Block Locking

Both devices share a compatible pinout, status register, and software command set. These similarities enable a clean upgrade from the 28F008SA to LH28F008SC-V. When upgrading, it is important to note the following differences:

- Because of new feature support, the two devices have different device codes. This allows for software optimization.
- $V_{PPLK}$  has been lowered from 6.5V to 1.5V to support 5V block erase, byte write, and lock-bit configuration operations. Designs that switch  $V_{PP}$  off during read operations should make sure that the  $V_{PP}$  voltage transitions to GND.
- To take advantage of SmartVoltage technology, allow  $V_{PP}$  connection to 5V.

#### 1.2 Product Overview

The LH28F008SC-V is a high-performance 8-Mbit SmartVoltage Flash memory organized as 1 Mbyte of

8 bits. The 1 Mbyte of data is arranged in sixteen 64-Kbyte blocks which are individually erasable, lockable, and unlockable in-system. The memory map is shown in Figure 6.

SmartVoltage technology provides a choice of  $V_{CC}$  and  $V_{PP}$  combinations, as shown in Table 1, to meet system performance and power expectations.  $V_{PP}$  at 5V eliminates the need for a separate 12V converter, while  $V_{PP}=12V$  maximizes block erase and byte write performance. In addition to flexible erase and program voltages, the dedicated  $V_{PP}$  pin gives complete data protection when  $V_{PP} \leq V_{PPLK}$ .

**Table 1.  $V_{CC}$  and  $V_{PP}$  Voltage Combinations Offered by SmartVoltage Technology**

$V_{CC}$ Voltage	$V_{PP}$ Voltage
5V	5V, 12V

Internal  $V_{CC}$  and  $V_{PP}$  detection Circuitry automatically configures the device for optimized read and write operations.

A Command User Interface (CUI) serves as the interface between the system processor and internal operation of the device. A valid command sequence written to the CUI initiates device automation. An internal Write State Machine (WSM) automatically executes the algorithms and timings necessary for block erase, byte write, and lock-bit configuration operations.

A block erase operation erases one of the device's 64-Kbyte blocks typically within 1 second (5V  $V_{CC}$ , 12V  $V_{PP}$ ) independent of other blocks. Each block can be independently erased 100,000 times (1.6 million block erases per device). Block erase suspend mode allows system software to suspend block erase to read or write data from any other block.

Writing memory data is performed in byte increments typically within 6  $\mu$ s (5V  $V_{CC}$ , 12V  $V_{PP}$ ). Byte write suspend mode enables the system to read data or execute code from any other flash memory array location.

Individual block locking uses a combination of bits, sixteen block lock-bits and a master lock-bit, to lock and unlock blocks. Block lock-bits gate block erase and byte write operations, while the master lock-bit gates block lock-bit modification. Lock-bit configuration operations (Set Block Lock-Bit, Set Master Lock-Bit, and Clear Block Lock-Bits commands) set and cleared lock-bits.

The status register indicates when the WSM's block erase, byte write, or lock-bit configuration operation is finished.

The RY/BY# output gives an additional indicator of WSM activity by providing both a hardware signal of status (versus software polling) and status masking (interrupt masking for background block erase, for example). Status polling using RY/BY# minimizes both CPU overhead and system power consumption. When low, RY/BY# indicates that the WSM is performing a block erase, byte write, or lock-bit configuration. RY/BY#-high indicates that the WSM is ready for a new command, block erase is suspended (and byte write is inactive), byte write is suspended, or the device is in deep power-down mode.

The access time is 85 ns ( $t_{AVAV}$ ) over the commercial temperature range (0°C to +70°C) and  $V_{CC}$  supply voltage range of 4.75V-5.25V. At lower  $V_{CC}$  voltage, the access time is 90ns (4.5V-5.5V).

The Automatic Power Savings (APS) feature substantially reduces active current when the device is in static mode (addresses not switching). In APS mode, the typical  $I_{CCR}$  current is 1 mA at 5V  $V_{CC}$ .

When CE# and RP# pins are at  $V_{CC}$ , the  $I_{CC}$  CMOS standby mode is enabled. When the RP# pin is at GND, deep power-down mode is enabled which minimizes power consumption and provides write protection during reset. A reset time ( $t_{PHQV}$ ) is required from RP# switching high until outputs are valid. Likewise, the device has a wake time ( $t_{PHEL}$ ) from RP#-high until writes to the CUI are recognized. With RP# at GND, the WSM is reset and the status register is cleared.

The device is available in 40-lead TSOP (Thin Small Outline Package, 1.2 mm thick), 44-lead PSOP (Plastic Small Outline Package) and 42-lead CSP (Chip Size Package). Pinouts are shown in Figures 2, 3, 4 and 5.

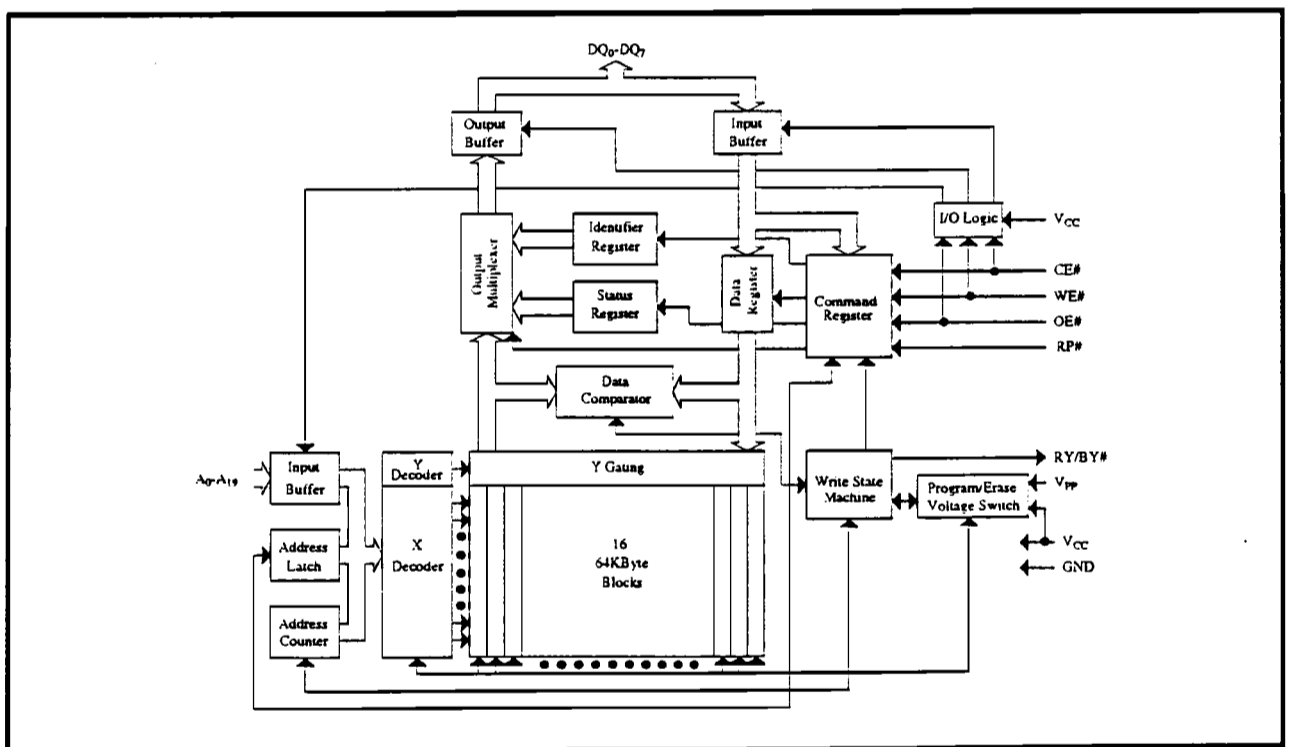

Figure 1. Block Diagram

Table 2. Pin Descriptions

Sym	Type	Name and Function
A <sub>0</sub> -A <sub>19</sub>	INPUT	<b>ADDRESS INPUTS:</b> Inputs for addresses during read and write operations. Addresses are internally latched during a write cycle.
DQ <sub>0</sub> -DQ <sub>7</sub>	INPUT/ OUTPUT	<b>DATA INPUT/OUTPUTS:</b> Inputs data and commands during CUI write cycles; outputs data during memory array, status register, and identifier code read cycles. Data pins float to high-impedance when the chip is deselected or outputs are disabled. Data is internally latched during a write cycle.
CE#	INPUT	<b>CHIP ENABLE:</b> Activates the device's control logic, input buffers, decoders, and sense amplifiers. CE#-high deselects the device and reduces power consumption to standby levels.
RP#	INPUT	<b>RESET/DEEP POWER-DOWN:</b> Puts the device in deep power-down mode and resets internal automation. RP#-high enables normal operation. When driven low, RP# inhibits write operations which provides data protection during power transitions. Exit from deep power-down sets the device to read array mode. RP# at V <sub>HH</sub> enables setting of the master lock-bit and enables configuration of block lock-bits when the master lock-bit is set. RP#=V <sub>HH</sub> overrides block lock-bits thereby enabling block erase and byte write operations to locked memory blocks. Block erase, byte write, or lock-bit configuration with V <sub>HH</sub> <RP#<V <sub>HH</sub> produce spurious results and should not be attempted.
OE#	INPUT	<b>OUTPUT ENABLE:</b> Gates the device's outputs during a read cycle.
WE#	INPUT	<b>WRITE ENABLE:</b> Controls writes to the CUI and array blocks. Addresses and data are latched on the rising edge of the WE# pulse.
RY/BY#	OUTPUT	<b>READY/BUSY#:</b> Indicates the status of the internal WSM. When low, the WSM is performing an internal operation (block erase, byte write, or lock-bit configuration). RY/BY#-high indicates that the WSM is ready for new commands, block erase is suspended, and byte write is inactive, byte write is suspended, or the device is in deep power-down mode. RY/BY# is always active and does not float when the chip is deselected or data outputs are disabled.
V <sub>PP</sub>	SUPPLY	<b>BLOCK ERASE, BYTE WRITE, LOCK-BIT CONFIGURATION POWER SUPPLY:</b> For erasing array blocks, writing bytes, or configuring lock-bits. With V <sub>PP</sub> ≤V <sub>PPLK</sub> , memory contents cannot be altered. Block erase, byte write, and lock-bit configuration with an invalid V <sub>PP</sub> (see DC Characteristics) produce spurious results and should not be attempted.
V <sub>CC</sub>	SUPPLY	<b>DEVICE POWER SUPPLY:</b> Do not float any power pins. With V <sub>CC</sub> ≤V <sub>LKO</sub> , all write attempts to the flash memory are inhibited. Device operations at invalid V <sub>CC</sub> voltage (see DC Characteristics) produce spurious results and should not be attempted.
GND	SUPPLY	<b>GROUND:</b> Do not float any ground pins.
NC		<b>NO CONNECT:</b> Lead is not internal connected; it may be driven or floated.

## 2 PRINCIPLES OF OPERATION

The LH28F008SC-V SmartVoltage Flash memory includes an on-chip WSM to manage block erase, byte write, and lock-bit configuration functions. It allows for: 100% TTL-level control inputs, fixed power supplies during block erasure, byte write, and lock-bit configuration, and minimal processor overhead with RAM-Like interface timings.

After initial device power-up or return from deep power-down mode (see Bus Operations), the device defaults to read array mode. Manipulation of external memory control pins allow array read, standby, and output disable operations.

Status register and identifier codes can be accessed through the CUI independent of the  $V_{PP}$  voltage. High voltage on  $V_{PP}$  enables successful block erasure, byte writing, and lock-bit configuration. All functions associated with altering memory contents—block erase, byte write, Lock-bit configuration, status, and identifier codes—are accessed via the CUI and verified through the status register.

Commands are written using standard microprocessor write timings. The CUI contents serve as input to the WSM, which controls the block erase, byte write, and lock-bit configuration. The internal algorithms are regulated by the WSM, including pulse repetition, internal verification, and margining of data. Addresses and data are internally latch during write cycles. Writing the appropriate command outputs array data, accesses the identifier codes, or outputs status register data.

Interface software that initiates and polls progress of block erase, byte write, and lock-bit configuration can be stored in any block. This code is copied to and executed from system RAM during flash memory updates. After successful completion, reads are again possible via the Read Array command. Block erase suspend allows system software to suspend a block erase to read or write data from any other block. Byte write suspend allows system software to suspend a byte write to read data from any other flash memory array location.

Figure 6. Memory Map

### 2.1 Data Protection

Depending on the application, the system designer may choose to make the  $V_{PP}$  power supply switchable (available only when memory block erases, byte writes, or lock-bit configurations are required) or hardwired to  $V_{PPH1/2}$ . The device accommodates either design practice and encourages optimization of the processor-memory interface.

## LH28F008SC-V SmartVoltage Flash MEMORY

When  $V_{PP} \leq V_{PPLK}$ , memory contents cannot be altered. The CUI, with two-step block erase, byte write, or lock-bit configuration command sequences, provides protection from unwanted operations even when high voltage is applied to  $V_{PP}$ . All write functions are disabled when  $V_{CC}$  is below the write lockout voltage  $V_{LKO}$  or when  $RP\#$  is at  $V_{IL}$ . The device's block locking capability provides additional protection from inadvertent code or data alteration by gating erase and byte write operations.

### 3 BUS OPERATION

The local CPU reads and writes flash memory in-system. All bus cycles to or from the flash memory conform to standard microprocessor bus cycles.

#### 3.1 Read

Information can be read from any block, identifier codes, or status register independent of the  $V_{PP}$  voltage.  $RP\#$  can be at either  $V_{IH}$  or  $V_{HH}$ .

The first task is to write the appropriate read mode command (Read Array, Read Identifier Codes, or Read Status Register) to the CUI. Upon initial device power-up or after exit from deep power-down mode, the device automatically resets to read array mode. Four control pins dictate the data flow in and out of the component:  $CE\#$ ,  $OE\#$ ,  $WE\#$ , and  $RP\#$ .  $CE\#$  and  $OE\#$  must be driven active to obtain data at the outputs.  $CE\#$  is the device selection control, and when active enables the selected memory device.  $OE\#$  is the data output ( $DQ_0$ - $DQ_7$ ) control and when active drives the selected memory data onto the I/O bus.  $WE\#$  must be at  $V_{IH}$  and  $RP\#$  must be at  $V_{IH}$  or  $V_{HH}$ . Figure 17 illustrates a read cycle.

#### 3.2 Output Disable

With  $OE\#$  at a logic-high level ( $V_{IH}$ ), the device outputs are disabled. Output pins  $DQ_0$ - $DQ_7$  are placed in a high-impedance state.

#### 3.3 Standby

$CE\#$  at a logic-high level ( $V_{IH}$ ) places the device in standby mode which substantially reduces device power consumption.  $DQ_0$ - $DQ_7$  outputs are placed in a high-impedance state independent of  $OE\#$ . If deselected during block erase, byte write, or lock-bit configuration, the device continues functioning, and consuming active power until the operation completes.

#### 3.4 Deep Power-Down

$RP\#$  at  $V_{IL}$  initiates the deep power-down mode.

In read modes,  $RP\#$ -low deselects the memory, places output drivers in a high-impedance state and turns off all internal circuits.  $RP\#$  must be held low for a minimum of 100 ns. Time  $t_{PHQV}$  is required after return from power-down until initial memory access outputs are valid. After this wake-up interval, normal operation is restored. The CUI is reset to read array mode and status register is set to 80H.

During block erase, byte write, or lock-bit configuration modes,  $RP\#$ -low will abort the operation.  $RY/BY\#$  remains low until the reset operation is complete. Memory contents being altered are no longer valid; the data may be partially erased or written. Time  $t_{PHWL}$  is required after  $RP\#$  goes to logic-high ( $V_{IH}$ ) before another command can be written.

As with any automated device, it is important to assert  $RP\#$  during system reset. When the system comes out of reset, it expects to read from the flash memory. Automated flash memories provide status information when accessed during block erase, byte write, or lock-bit configuration modes. If a CPU reset occurs with no flash memory reset, proper CPU initialization may not occur because the flash memory may be providing status information instead of array data. SHARP's flash memories allow proper CPU initialization following a system reset through the use of the  $RP\#$  input. In this application,  $RP\#$  is controlled by the same  $RESET\#$  signal that resets the system CPU.

### 3.5 Read Identifier Codes Operation

The read identifier codes operation outputs the manufacturer code, device code, block lock configuration codes for each block, and the master lock configuration code (see Figure 7). Using the manufacturer and device codes, the system CPU can automatically match the device with its proper algorithms. The block lock and master lock configuration codes identify locked and unlocked blocks and master lock-bit setting.

Figure 7. Device Identifier Code Memory Map

### 3.6 Write

Writing commands to the CUI enable reading of device data and identifier codes. They also control inspection and clearing of the status register. When  $V_{PP}=V_{PPH1/2}$ , the CUI additionally controls block erasure, byte write, and lock-bit configuration.

The Block Erase command requires appropriate command data and an address within the block to be erased. The Byte Write command requires the command and address of the location to be written. Set Master and Block Lock-Bit commands require the command and address within the device (Master Lock) or block within the device (Block Lock) to be locked. The Clear Block Lock-Bits command requires the command and address within the device.

The CUI does not occupy an addressable memory location. It is written when WE# and CE# are active. The address and data needed to execute a command are latched on the rising edge of WE# or CE# (whichever goes high first). Standard microprocessor write timings are used. Figures 18 and 19 illustrate WE# and CE#-controlled write operations.

## 4 COMMAND DEFINITIONS

When the  $V_{PP}$  voltage  $\leq V_{PPLK}$ , Read operations from the status register, identifier codes, or blocks are enabled. Placing  $V_{PPH1/2}$  on  $V_{PP}$  enables successful block erase, byte write and lock-bit configuration operations.

Device operations are selected by writing specific commands into the CUI. Table 4 defines these commands.

## LH28F008SC-V SmartVoltage Flash MEMORY

**Table 3. Bus Operations**

Mode	Notes	RP#	CE#	OE#	WE#	Address	V <sub>pp</sub>	DQ <sub>0-7</sub>	RY/BY#
Read	1,2,3	V <sub>IH</sub> or V <sub>HH</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IH</sub>	X	X	D <sub>OUT</sub>	X
Output Disable	3	V <sub>IH</sub> or V <sub>HH</sub>	V <sub>IL</sub>	V <sub>IH</sub>	V <sub>IH</sub>	X	X	High Z	X
Standby	3	V <sub>IH</sub> or V <sub>HH</sub>	V <sub>IH</sub>	X	X	X	X	High Z	X
Deep Power-Down	4	V <sub>IL</sub>	X	X	X	X	X	High Z	V <sub>OH</sub>
Read Identifier Codes		V <sub>IH</sub> or V <sub>HH</sub>	V <sub>IL</sub>	V <sub>IL</sub>	V <sub>IH</sub>	See Figure 7	X	Note 5	V <sub>OH</sub>
Write	3,6,7	V <sub>IH</sub> or V <sub>HH</sub>	V <sub>IL</sub>	V <sub>IH</sub>	V <sub>IL</sub>	X	X	D <sub>IN</sub>	X

**NOTES:**

1. Refer to DC Characteristics. When  $V_{pp} \leq V_{ppLK}$ , memory contents can be read, but not altered.
2. X can be V<sub>IL</sub> or V<sub>IH</sub> for control pins and addresses, and V<sub>ppLK</sub> or V<sub>ppH1/2</sub> for V<sub>pp</sub>. See DC Characteristics for V<sub>ppLK</sub> and V<sub>ppH1/2</sub> voltages.
3. RY/BY# is V<sub>OL</sub> when the WSM is executing internal block erase, byte write, or lock-bit configuration algorithms. It is V<sub>OH</sub> during when the WSM is not busy, in block erase suspend mode (with byte write inactive), byte write suspend mode, or deep power-down mode.
4. RP# at GND±0.2V ensures the lowest deep power-down current.
5. See Section 4.2 for read identifier code data.
6. Command writes involving block erase, write, or lock-bit configuration are reliably executed when  $V_{pp} = V_{ppH1/2}$  and  $V_{CC} = V_{CC1/2}$ . Block erase, byte write, or lock-bit configuration with  $V_{IH} < RP# < V_{HH}$  produce spurious results and should not be attempted.
7. Refer to Table 4 for valid D<sub>IN</sub> during a write operation.

Table 4. Command Definitions<sup>(9)</sup>

Command	Bus Cycles Req'd.	Notes	First Bus Cycle			Second Bus Cycle		
			Oper <sup>(1)</sup>	Addr <sup>(2)</sup>	Data <sup>(3)</sup>	Oper <sup>(1)</sup>	Addr <sup>(2)</sup>	Data <sup>(3)</sup>
Read Array/Reset	1		Write	X	FFH			
Read Identifier Codes	≥2	4	Write	X	90H	Read	IA	ID
Read Status Register	2		Write	X	70H	Read	X	SRD
Clear Status Register	1		Write	X	50H			
Block Erase	2	5	Write	BA	20H	Write	BA	D0H
Byte Write	2	5,6	Write	WA	40H or 10H	Write	WA	WD
Block Erase and Byte Write Suspend	1	5	Write	X	B0H			
Block Erase and Byte Write Resume	1	5	Write	X	D0H			
Set Block Lock-Bit	2	7	Write	BA	60H	Write	BA	01H
Set Master Lock-Bit	2	7	Write	X	60H	Write	X	F1H
Clear Block Lock-Bits	2	8	Write	X	60H	Write	X	D0H

**NOTES:**

- BUS operations are defined in Table 3.
- X=Any valid address within the device.  
IA=Identifier Code Address: see Figure 7.  
BA=Address within the block being erased or locked.  
WA=Address of memory location to be written.
- SRD=Data read from status register. See Table 7 for a description of the status register bits.  
WD=Data to be written at location WA. Data is latched on the rising edge of WE# or CE# (whichever goes high first).  
ID=Data read from identifier codes.
- Following the Read Identifier Codes command, read operations access manufacturer, device, block lock, and master lock codes. See Section 4.2 for read identifier code data.
- If the block is locked, RP# must be at V<sub>HH</sub> to enable block erase or byte write operations. Attempts to issue a block erase or byte write to a locked block while RP# is V<sub>IH</sub>.
- Either 40H or 10H are recognized by the WSM as the byte write setup.
- If the master lock-bit is set, RP# must be at V<sub>HH</sub> to set a block lock-bit. RP# must be at V<sub>HH</sub> to set the master lock-bit. If the master lock-bit is not set, a block lock-bit can be set while RP# is V<sub>IH</sub>.
- If the master lock-bit is set, RP# must be at V<sub>HH</sub> to clear block lock-bits. The clear block lock-bits operation simultaneously clears all block lock-bits. If the master lock-bit is not set, the Clear Block Lock-Bits command can be done while RP# is V<sub>IH</sub>.
- Commands other than those shown above are reserved by SHARP for future device implementations and should not be used.

### 4.1 Read Array Command

Upon initial device power-up and after exit from deep power-down mode, the device defaults to read array mode. This operation is also initiated by writing the Read Array command. The device remains enabled for reads until another command is written. Once the internal WSM has started a block erase, byte write or lock-bit configuration, the device will not recognize the Read Array command until the WSM completes its operation unless the WSM is suspended via an Erase Suspend or Byte Write Suspend command. The Read Array command functions independently of the  $V_{PP}$  voltage and RP# can be  $V_{IH}$  or  $V_{HH}$ .

### 4.2 Read Identifier Codes Command

The identifier code operation is initiated by writing the Read Identifier Codes command. Following the command write, read cycles from addresses shown in Figure 7 retrieve the manufacturer, device, block lock configuration and master lock configuration codes (see Table 5 for identifier code values). To terminate the operation, write another valid command. Like the Read Array command, the Read Identifier Codes command functions independently of the  $V_{PP}$  voltage and RP# can be  $V_{IH}$  or  $V_{HH}$ . Following the Read Identifier Codes command, the following information can be read:

Table 5. Identifier Codes

Code	Address	Data
Manufacture Code	00000	89
Device Code	00001	A6
Block Lock Configuration	X0002 <sup>(1)</sup>	
•Block is Unlocked		DQ <sub>0</sub> =0
•Block is Locked		DQ <sub>0</sub> =1
•Reserved for Future Use		DQ <sub>1-7</sub>
Master Lock Configuration	00003	
•Device is Unlocked		DQ <sub>0</sub> =0
•Device is Locked		DQ <sub>0</sub> =1
•Reserved for Future Use		DQ <sub>1-7</sub>

**NOTE:**

1. X selects the specific block lock configuration code to be read. See Figure 7 for the device identifier code memory map.

### 4.3 Read Status Register Command

The status register may be read to determine when a block erase, byte write, or lock-bit configuration is complete and whether the operation completed successfully. It may be read at any time by writing the Read Status Register command. After writing this command, all subsequent read operations output data from the status register until another valid command is written. The status register contents are latched on the falling edge of OE# or CE#, whichever occurs. OE# or CE# must toggle to  $V_{IH}$  before further reads to update the status register latch. The Read Status Register command functions independently of the  $V_{PP}$  voltage. RP# can be  $V_{IH}$  or  $V_{HH}$ .

### 4.4 Clear Status Register Command

Status register bits SR.5, SR.4, SR.3, and SR.1 are set to "1"s by the WSM and can only be reset by the Clear Status Register command. These bits indicate various failure conditions (see Table 7). By allowing system software to reset these bits, several operations (such as cumulatively erasing or locking multiple blocks or writing several bytes in sequence) may be performed. The status register may be polled to determine if an error occurred during the sequence.

To clear the status register, the Clear Status Register command (50H) is written. It functions independently of the applied  $V_{PP}$  Voltage. RP# can be  $V_{IH}$  or  $V_{HH}$ . This command is not functional during block erase or byte write suspend modes.

### 4.5 Block Erase Command

Erase is executed one block at a time and initiated by a two-cycle command. A block erase setup is first written, followed by an block erase confirm. This command sequence requires appropriate sequencing and an address within the block to be erased (erase changes all block data to FFH). Block preconditioning, erase, and verify are handled internally by the WSM (invisible to the system). After the two-cycle block erase sequence is written, the device automatically outputs status register data when read (see Figure 8). The CPU can detect block erase completion by analyzing the output data of the RY/BY# pin or status register bit SR.7.

When the block erase is complete, status register bit SR.5 should be checked. If a block erase error is detected, the status register should be cleared before system software attempts corrective actions. The CUI remains in read status register mode until a new command is issued.

This two-step command sequence of set-up followed by execution ensures that block contents are not accidentally erased. An invalid Block Erase command sequence will result in both status register bits SR.4 and SR.5 being set to "1". Also, reliable block erasure can only occur when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1/2}$ . In the absence of this high voltage, block contents are protected against erasure. If block erase is attempted while  $V_{PP}\leq V_{PPLK}$ , SR.3 and SR.5 will be set to "1". Successful block erase requires that the corresponding block lock-bit be cleared or, if set, that  $RP#=V_{HH}$ . If block erase is attempted when the corresponding block lock-bit is set and  $RP#=V_{IH}$ , SR.1 and SR.5 will be set to "1". Block erase operations with  $V_{IH}<RP#<V_{HH}$  produce spurious results and should not be attempted.

#### 4.6 Byte Write Command

Byte write is executed by a two-cycle command sequence. Byte write setup (standard 40H or alternate 10H) is written, followed by a second write that specifies the address and data (latched on the rising edge of WE#). The WSM then takes over, controlling the byte write and write verify algorithms internally. After the byte write sequence is written, the device automatically outputs status register data when read (see Figure 9). The CPU can detect the completion of the byte write event by analyzing the RY/BY# pin or status register bit SR.7.

When byte write is complete, status register bit SR.4 should be checked. If byte write error is detected, the status register should be cleared. The internal WSM verify only detects errors for "1"s that do not successfully write to "0"s. The CUI remains in read status register mode until it receives another command.

Reliable byte writes can only occur when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1/2}$ . In the absence of this high voltage, memory contents are protected against byte writes. If byte write is attempted while  $V_{PP}\leq V_{PPLK}$ , status register bits SR.3 and SR.4 will be set to "1".

Successful byte write requires that the corresponding block lock-bit be cleared or, if set, that  $RP#=V_{HH}$ . If byte write is attempted when the corresponding block lock-bit is set and  $RP#=V_{IH}$ , SR.1 and SR.4 will be set to "1". Byte write operations with  $V_{IH}<RP#<V_{HH}$  produce spurious results and should not be attempted.

#### 4.7 Block Erase Suspend Command

The Block Erase Suspend command allows block-erase interruption to read or byte-write data in another block of memory. Once the block-erase process starts, writing the Block Erase Suspend command requests that the WSM suspend the block erase sequence at a predetermined point in the algorithm. The device outputs status register data when read after the Block Erase Suspend command is written. Polling status register bits SR.7 and SR.6 can determine when the block erase operation has been suspended (both will be set to "1"). RY/BY# will also transition to  $V_{OH}$ . Specification  $t_{WHRH2}$  defines the block erase suspend latency.

At this point, a Read Array command can be written to read data from blocks other than that which is suspended. A Byte Write command sequence can also be issued during erase suspend to program data in other blocks. Using the Byte Write Suspend command (see Section 4.8), a byte write operation can also be suspended. During a byte write operation with block erase suspended, status register bit SR.7 will return to "0" and the RY/BY# output will transition to  $V_{OL}$ . However, SR.6 will remain "1" to indicate block erase suspend status.

The only other valid commands while block erase is suspended are Read Status Register and Block Erase Resume. After a Block Erase Resume command is written to the flash memory, the WSM will continue the block erase process. Status register bits SR.6 and SR.7 will automatically clear and RY/BY# will return to  $V_{OL}$ . After the Erase Resume command is written, the device automatically outputs status register data when read (see Figure 10).  $V_{PP}$  must remain at  $V_{PPH1/2}$  (the same  $V_{PP}$  level used for block erase) while block erase is suspended.  $RP\#$  must also remain at  $V_{IH}$  or  $V_{HH}$  (the same  $RP\#$  level used for block erase). Block erase cannot resume until byte write operations initiated during block erase suspend have completed.

#### 4.8 Byte Write Suspend Command

The Byte Write Suspend command allows byte write interruption to read data in other flash memory locations. Once the byte write process starts, writing the Byte Write Suspend command requests that the WSM suspend the byte write sequence at a predetermined point in the algorithm. The device continues to output status register data when read after the Byte Write Suspend command is written. Polling status register bits SR.7 and SR.2 can determine when the byte write operation has been suspended (both will be set to "1"). RY/BY# will also transition to  $V_{OH}$ . Specification  $t_{WHRH1}$  defines the byte write suspend latency.

At this point, a Read Array command can be written to read data from locations other than that which is suspended. The only other valid commands while byte write is suspended are Read Status Register and Byte Write Resume. After Byte Write Resume command is written to the flash memory, the WSM will continue the byte write process. Status register bits SR.2 and SR.7 will automatically clear and RY/BY# will return to  $V_{OL}$ . After the Byte Write Resume command is written, the device automatically outputs status register data when read (see Figure 11).  $V_{PP}$  must remain at  $V_{PPH1/2}$  (the same  $V_{PP}$  level used for byte write) while in byte write suspend mode. RP# must also remain at  $V_{IH}$  or  $V_{HH}$  (the same RP# level used for byte write).

#### 4.9 Set Block and Master Lock-Bit Commands

A flexible block locking and unlocking scheme is enabled via a combination of block lock-bits and a master lock-bit. The block lock-bits gate program and erase operations while the master lock-bit gates block-lock bit modification. With the master lock-bit not set, individual block lock-bits can be set using the Set Block Lock-Bit command. The Set Master Lock-Bit command, in conjunction with  $RP\#=V_{HH}$ , sets the master lock-bit. After the master lock-bit is set, subsequent setting of block lock-bits requires both the Set Block Lock-Bit command and  $V_{HH}$  on the RP# pin. See Table 6 for a summary of hardware and software write protection options.

Set block lock-bit and master lock-bit are executed by a two-cycle command sequence. The set block or master lock-bit setup along with appropriate block or device address is written followed by either the set block lock-bit confirm (and an address within the block to be locked) or the set master lock-bit confirm (and any device address). The WSM then controls the set lock-bit algorithm. After the sequence is written, the device automatically outputs status register data when read (see Figure 12). The CPU can detect the completion of the set lock-bit event by analyzing the RY/BY# pin output or status register bit SR.7.

When the set lock-bit operation is complete, status register bit SR.4 should be checked. If an error is detected, the status register should be cleared. The CUI will remain in read status register mode until a new command is issued.

This two-step sequence of set-up followed by execution ensures that lock-bits are not accidentally set. An invalid Set Block or Master Lock-Bit command will result in status register bits SR.4 and SR.5 being set to "1". Also, reliable operations occur only when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1/2}$ . In the absence of this high voltage, lock-bit contents are protected against alteration.

A successful set block lock-bit operation requires that the master lock-bit be cleared or, if the master lock-bit is set, that  $RP\#=V_{HH}$ . If it is attempted with the master lock-bit set and  $RP\#=V_{IH}$ , SR.1 and SR.4 will be set to "1" and the operation will fail. Set block lock-bit operations while  $V_{IH}<RP\#<V_{HH}$  produce spurious results and should not be attempted. A successful set master lock-bit operation requires that  $RP\#=V_{HH}$ . If it is attempted with  $RP\#=V_{IH}$ , SR.1 and SR.4 will be set to "1" and the operation will fail. Set master lock-bit operations with  $V_{IH}<RP\#<V_{HH}$  produce spurious results and should not be attempted.

### 4.10 Clear Block Lock-Bits Command

All set block lock-bits are cleared in parallel via the Clear Block Lock-Bits command. With the master lock-bit not set, block lock-bits can be cleared using only the Clear Block Lock-Bits command. If the master lock-bit is set, clearing block lock-bits requires both the Clear Block Lock-Bits command and  $V_{HH}$  on the RP# pin. See Table 6 for a summary of hardware and software write protection options.

Clear block lock-bits operation is executed by a two-cycle command sequence. A clear block lock-bits setup is first written. After the command is written, the device automatically outputs status register data when read (see Figure 13). The CPU can detect completion of the clear block lock-bits event by analyzing the RY/BY# Pin output or status register bit SR.7.

When the operation is complete, status register bit SR.5 should be checked. If a clear block lock-bit error is detected, the status register should be cleared. The CUI will remain in read status register mode until another command is issued.

This two-step sequence of set-up followed by execution ensures that block lock-bits are not accidentally cleared. An invalid Clear Block Lock-Bits command sequence will result in status register bits SR.4 and SR.5 being set to "1". Also, a reliable clear block lock-bits operation can only occur when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1/2}$ . If a clear block lock-bits operation is attempted while  $V_{PP}\leq V_{PPLK}$ , SR.3 and SR.5 will be set to "1". In the absence of this high voltage, the block lock-bits content are protected against alteration. A successful clear block lock-bits operation requires that the master lock-bit is not set or, if the master lock-bit is set, that  $RP\#=V_{HH}$ . If it is attempted with the master lock-bit set and  $RP\#=V_{IH}$ , SR.1 and SR.5 will be set to "1" and the operation will fail. A clear block lock-bits operation with  $V_{IH}<RP\#<V_{HH}$  produce spurious results and should not be attempted.

If a clear block lock-bits operation is aborted due to  $V_{PP}$  or  $V_{CC}$  transitioning out of valid range or RP# active transition, block lock-bit values are left in an undetermined state. A repeat of clear block lock-bits is required to initialize block lock-bit contents to known values. Once the master lock-bit is set, it cannot be cleared.

Table 6. Write Protection Alternatives

Operation	Master Lock-Bit	Block Lock-Bit	RP#	Effect		
Block Erase or Byte Write	X	0	$V_{IH}$ or $V_{HH}$	Block Erase and Byte Write Enabled		
		1	$V_{IH}$	Block is Locked. Block Erase and Byte Write Disabled		
			$V_{HH}$	Block Lock-Bit Override. Block Erase and Byte Write Enabled		
Set Block Lock-Bit	0	X	$V_{IH}$ or $V_{HH}$	Set Block Lock-Bit Enabled		
	1	X	$V_{IH}$	Master Lock-Bit is Set. Set Block Lock-Bit Disabled		
			$V_{HH}$	Master Lock-Bit Override. Set Block Lock-Bit Enabled		
Set Master Lock-Bit	X	X	$V_{IH}$	Set Master Lock-Bit Disabled		
			$V_{HH}$	Set Master Lock-Bit Enabled		
Clear Block Lock-Bits	0	X	$V_{IH}$ or $V_{HH}$	Clear Block Lock-Bits Enabled		
			1	X	$V_{IH}$	Master Lock-Bit is Set. Clear Block Lock-Bits Disabled
					$V_{HH}$	Master Lock-Bit Override. Clear Block Lock-Bits Enabled

**Table 7. Status Register Definition**

## 5 DESIGN CONSIDERATIONS

### 5.1 Three-Line Output Control

The device will often be used in large memory arrays. SHARP provides three control inputs to accommodate multiple memory connections. Three-line control provides for:

- a. Lowest possible memory power dissipation.
- b. Complete assurance that data bus contention will not occur.

To use these control inputs efficiently, an address decoder should enable CE# while OE# should be connected to all memory devices and the system's READ# control line. This assures that only selected memory devices have active outputs while deselected memory devices are in standby mode. RP# should be connected to the system POWERGOOD signal to prevent unintended writes during system power transitions. POWERGOOD should also toggle during system reset.

### 5.2 RY/BY# and Block Erase, Byte Write, and Lock-Bit Configuration Polling

RY/BY# is a full CMOS output that provides a hardware method of detecting block erase, byte write and lock-bit configuration completion. It transitions low after block erase, byte write, or lock-bit configuration commands and returns to  $V_{OH}$  when the WSM has finished executing the internal algorithm.

RY/BY# can be connected to an interrupt input of the system CPU or controller. It is active at all times. RY/BY# is also  $V_{OH}$  when the device is in block erase suspend (with byte write inactive), byte write suspend or deep power-down modes.

### 5.3 Power Supply Decoupling

Flash memory power switching characteristics require careful device decoupling. System designers are interested in three supply current issues; standby current levels, active current levels and transient peaks produced by falling and rising edges of CE# and OE#. Transient current magnitudes depend on the device outputs' capacitive and inductive loading. Two-line control and proper decoupling capacitor selection will suppress transient voltage peaks. Each device should have a 0.1  $\mu\text{F}$  ceramic capacitor connected between its  $V_{CC}$  and GND and between its  $V_{PP}$  and GND. These high-frequency, low inductance capacitors should be placed as close as possible to package leads. Additionally, for every eight devices, a 4.7  $\mu\text{F}$  electrolytic capacitor should be placed at the array's power supply connection between  $V_{CC}$  and GND. The bulk capacitor will overcome voltage slumps caused by PC board trace inductance.

### 5.4 $V_{PP}$ Trace on Printed Circuit Boards

Updating flash memories that reside in the target system requires that the printed circuit board designer pay attention to the  $V_{PP}$  Power supply trace. The  $V_{PP}$  pin supplies the memory cell current for byte writing and block erasing. Use similar trace widths and layout considerations given to the  $V_{CC}$  power bus. Adequate  $V_{PP}$  supply traces and decoupling will decrease  $V_{PP}$  voltage spikes and overshoots.

### 5.5 $V_{CC}$ , $V_{PP}$ , RP# Transitions

Block erase, byte write and lock-bit configuration are not guaranteed if  $V_{PP}$  falls outside of a valid  $V_{PPH1/2}$  range,  $V_{CC}$  falls outside of a valid  $V_{CC1/2}$  range, or  $RP\# = V_{IH}$  or  $V_{HH}$ . If  $V_{PP}$  error is detected, status register bit SR.3 is set to "1" along with SR.4 or SR.5, depending on the attempted operation. If RP# transitions to  $V_{IL}$  during block erase, byte write, or lock-bit configuration, RY/BY# will remain low until the reset operation is complete. Then, the operation will abort and the device will enter deep power-down. The aborted operation may leave data partially altered. Therefore, the command sequence must be repeated after normal operation is restored. Device power-off or RP# transitions to  $V_{IL}$  clear the status register.

The CUI latches commands issued by system software and is not altered by  $V_{PP}$  or CE# transitions or WSM actions. Its state is read array mode upon power-up, after exit from deep power-down or after  $V_{CC}$  transitions below  $V_{LKO}$ .

After block erase, byte write, or lock-bit configuration, even after  $V_{PP}$  transitions down to  $V_{PPLK}$ , the CUI must be placed in read array mode via the Read Array command if subsequent access to the memory array is desired.

### 5.6 Power-Up/Down Protection

The device is designed to offer protection against accidental block erasure, byte writing, or lock-bit configuration during power transitions. Upon power-up, the device is indifferent as to which power supply ( $V_{PP}$  or  $V_{CC}$ ) powers-up first. Internal circuitry resets the CUI to read array mode at power-up.

A system designer must guard against spurious writes for  $V_{CC}$  voltages above  $V_{LKO}$  when  $V_{PP}$  is active. Since both WE# and CE# must be low for a command write, driving either to  $V_{IH}$  will inhibit writes. The CUI's two-step command sequence architecture provides added level of protection against data alteration.

In-system block lock and unlock capability prevents inadvertent data alteration. The device is disabled while  $RP\# = V_{IL}$  regardless of its control inputs state.

### 5.7 Power Dissipation

When designing portable systems, designers must consider battery power consumption not only during device operation, but also for data retention during system idle time. Flash memory's nonvolatility increases usable battery life because data is retained when system power is removed.

In addition, deep power-down mode ensures extremely low power consumption even when system power is applied. For example, portable computing products and other power sensitive applications that use an array of devices for solid-state storage can consume negligible power by lowering RP# to  $V_{IL}$  standby or sleep modes. If access is again needed, the devices can be read following the  $t_{PHQV}$  and  $t_{PHWL}$  wake-up cycles required after RP# is first raised to  $V_{IH}$ . See AC Characteristics— Read Only and Write Operations and Figures 17, 18 and 19 for more information.

### 6 ELECTRICAL SPECIFICATIONS

#### 6.1 Absolute Maximum Ratings\*

Commercial Operating Temperature	
During Read, Block Erase, Byte Write	
and Lock-Bit Configuration .....	0°C to +70°C(1)
Temperature under Bias.....	-10°C to +80°C
Storage Temperature.....	-65°C to +125°C
Voltage On Any Pin	
(except V <sub>CC</sub> , V <sub>PP</sub> , and RP#).....	-2.0V to +7.0V(2)
V <sub>CC</sub> Supply Voltage.....	-2.0V to +7.0V(2)
V <sub>PP</sub> Update Voltage during	
Block Erase, Byte Write and	
Lock-Bit Configuration .....	-2.0V to +14.0V(2,3)
RP# Voltage with Respect to	
GND during Lock-Bit	
Configuration Operations .....	-2.0V to +14.0V(2,3)
Output Short Circuit Current .....	100mA(4)

**NOTICE:** This datasheet contains information on products in the design phase of development. Do not finalize a design with this information. Revised information will be published when the product is available. Verify with your local SHARP Sales office that you have the latest datasheet before finalizing a design.

*\*WARNING: Stressing the device beyond the "Absolute Maximum Ratings" may cause permanent damage. These are stress ratings only. Operation beyond the "Operating Conditions" is not recommended and extended exposure beyond the "Operating Conditions" may affect device reliability.*

#### NOTES:

1. Operating temperature is for commercial product defined by this specification.
2. All specified voltages are with respect to GND. Minimum DC voltage is -0.5V on input/output pins and -0.2V on V<sub>CC</sub> and V<sub>PP</sub> pins. During transitions, this level may undershoot to -2.0V for periods <20ns. Maximum DC voltage on input/output pins and V<sub>CC</sub> is V<sub>CC</sub>+0.5V which, during transitions, may overshoot to V<sub>CC</sub>+2.0V for periods <20ns.
3. Maximum DC voltage on V<sub>PP</sub> and RP# may overshoot to +14.0V for periods <20ns.
4. Output shorted for no more than one second. No more than one output shorted at a time.

#### 6.2 Operating Conditions

Temperature and V<sub>CC</sub> Operating Conditions

Symbol	Parameter	Notes	Min	Max	Unit	Test Condition
T <sub>A</sub>	Operating Temperature		0	+70	°C	Ambient Temperature
V <sub>CC1</sub>	V <sub>CC</sub> Supply Voltage (5V±5%)		4.75	5.25	V	
V <sub>CC2</sub>	V <sub>CC</sub> Supply Voltage (5V±10%)		4.50	5.50	V	

##### 6.2.1 CAPACITANCE(1)

T<sub>A</sub>=+25°C, f=1MHz

Symbol	Parameter	Typ	Max	Unit	Condition
C <sub>IN</sub>	Input Capacitance	6	8	pF	V <sub>IN</sub> =0.0V
C <sub>OUT</sub>	Output Capacitance	8	12	pF	V <sub>OUT</sub> =0.0V

**NOTE:**

1. Sampled, not 100% tested.

I <sub>PPE</sub>	V <sub>PP</sub> Block Erase or Clear Lock-Bit Current	1,7		20	mA	V <sub>PP</sub> =5.0V±10%
				15	mA	V <sub>PP</sub> =12.0V±5%
I <sub>PPWS</sub> I <sub>PPBS</sub>	V <sub>PP</sub> Byte Write or Block Erase Suspend Current	1		200	μA	V <sub>PP</sub> =V <sub>PPH1/2</sub>

### DC Characteristics (Continued)

Sym	Parameter	Notes	V <sub>CC</sub> =5V		Unit	Test Conditions
			Min	Max		
V <sub>IL</sub>	Input Low Voltage	7	-0.5	0.8	V	
V <sub>IH</sub>	Input High Voltage	7	2.0	V <sub>CC</sub> +0.5	V	
V <sub>OL</sub>	Output Low Voltage	3,7		0.45	V	V <sub>CC</sub> =V <sub>CC</sub> Min, I <sub>OL</sub> =5.8mA
V <sub>OH1</sub>	Output High Voltage (TTL)	3,7	2.4		V	V <sub>CC</sub> =V <sub>CC</sub> Min, I <sub>OH</sub> =-2.5mA
V <sub>OH2</sub>	Output High Voltage (CMOS)	3,7	0.85		V	V <sub>CC</sub> =V <sub>CC</sub> Min, I <sub>OH</sub> =-2.5μA
			V <sub>CC</sub> -0.4		V	V <sub>CC</sub> =V <sub>CC</sub> Min, I <sub>OH</sub> =-100μA
V <sub>PPLK</sub>	V <sub>PP</sub> Lockout during Normal Operations	4,7		1.5	V	
V <sub>PPH1</sub>	V <sub>PP</sub> during Byte Write, Block Erase, or Lock-Bit Operations		4.5	5.5	V	
V <sub>PPH2</sub>	V <sub>PP</sub> during Byte Write, Block Erase, or Lock-Bit Operations		11.4	12.6	V	
V <sub>IKO</sub>	V <sub>CC</sub> Lockout Voltage		2.0		V	
V <sub>HH</sub>	RP# Unlock Voltage	8	11.4	12.6	V	Set Master Lock-Bit Override Master and Block Lock-Bit

#### NOTES:

- All currents are in RMS unless otherwise noted. These currents are valid for all product versions (packages and speeds). Contact SHARP's Application Support Hotline or your local sales office for information about typical specifications.
- I<sub>CCWS</sub> and I<sub>CCES</sub> are specified with the device de-selected. If read or byte written while in erase suspend mode, the device's current draw is the sum of I<sub>CCWS</sub> or I<sub>CCES</sub> and I<sub>CCR</sub> or I<sub>CCW</sub>, respectively.
- Includes RY/BY#.
- Block erases, byte writes, and lock-bit configurations are inhibited when V<sub>PP</sub> ≤ V<sub>PPLK</sub>, and not guaranteed in the range between V<sub>PPLK</sub>(max) and V<sub>PPH1</sub>(min), between V<sub>PPH1</sub>(max) and V<sub>PPH2</sub>(min), and above V<sub>PPH2</sub>(max).
- Automatic Power Savings (APS) reduces typical I<sub>CCR</sub> to 1mA at 5V V<sub>CC</sub> in static operation.
- CMOS inputs are either V<sub>CC</sub>±0.2V or GND±0.2V. TTL inputs are either V<sub>IL</sub> or V<sub>IH</sub>.
- Sampled, not 100% tested.
- Master lock-bit set operations are inhibited when RP#=V<sub>IH</sub>. Block lock-bit configuration operations are inhibited when the master lock-bit is set and RP#=V<sub>IH</sub>. Block erases and byte writes are inhibited when the corresponding block-lock bit is set and RP#=V<sub>IH</sub>. Block erase, byte write, and lock-bit configuration operations are not guaranteed with V<sub>IH</sub> < RP# < V<sub>HH</sub>.

### 6.2.4 AC CHARACTERISTICS - READ-ONLY OPERATIONS<sup>(1)</sup>

$V_{CC}=5V\pm 0.5V, 5V\pm 0.25V, T_A=0^{\circ}C$  to  $+70^{\circ}C$

Versions <sup>(4)</sup>	Parameter	Notes	LH28F008SC-V85 <sup>(5)</sup>		LH28F008SC-V90 <sup>(6)</sup>		LH28F008SC-V120 <sup>(6)</sup>		Unit
			Min	Max	Min	Max	Min	Max	
$t_{AVAV}$	Read Cycle Time		85		90		120		ns
$t_{AVOQ}$	Address to Output Delay			85		90		120	ns
$t_{ELQV}$	CE# to Output Delay	2		85		90		120	ns
$t_{PHOV}$	RP# High to Output Delay			400		400		400	ns
$t_{GLOV}$	OE# to Output Delay	2		40		45		50	ns
$t_{ELOZ}$	CE# to Output in Low Z	3	0		0		0		ns
$t_{EHOZ}$	CE# High to Output in High Z	3		55		55		55	ns
$t_{GLOZ}$	OE# to Output in Low Z	3	0		0		0		ns
$t_{GHOZ}$	OE# High to Output in High Z	3		10		10		15	ns
$t_{OH}$	Output Hold from Address, CE# or OE# Change, Whichever Occurs First	3	0		0		0		ns

#### NOTES:

1. See AC Input/Output Reference Waveform for maximum allowable input slew rate.
2. OE# may be delayed up to  $t_{ELQV}-t_{GLOV}$  after the falling edge of CE# without impact on  $t_{ELQV}$ .
3. Sampled, not 100% tested.
4. See Ordering Information for device speeds (valid operational combinations).
5. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (High Speed Configuration) for testing characteristics.
6. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (Standard Configuration) for testing characteristics.

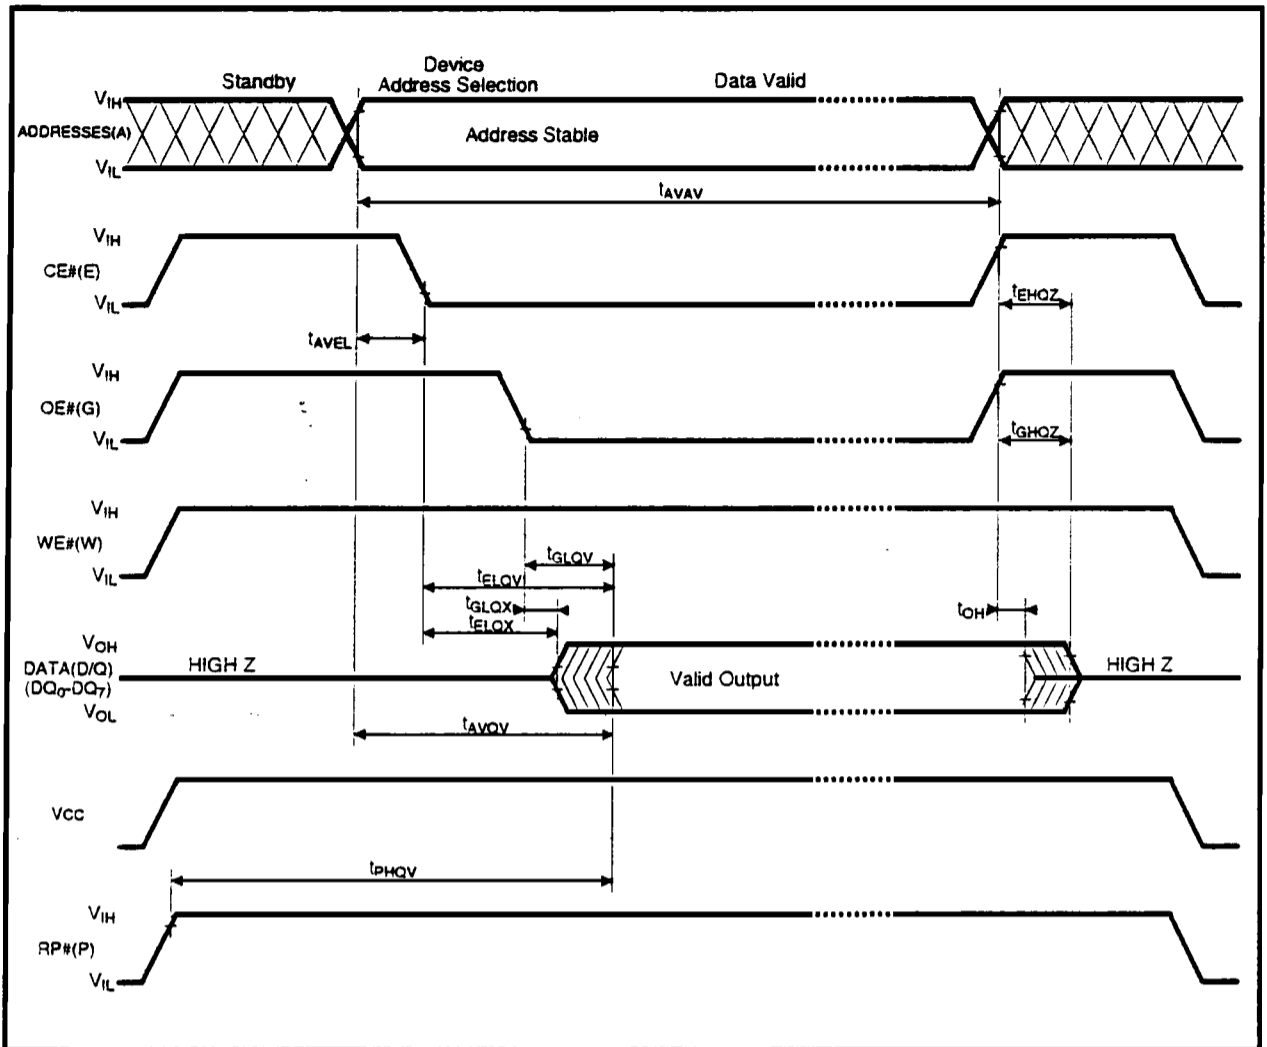

Figure 17. AC Waveform for Read Operations

### 6.2.5 AC CHARACTERISTICS - WRITE OPERATION<sup>(1)</sup>

$V_{CC}=5V\pm0.5V, 5V\pm0.25V, T_A=0^\circ C \text{ to } +70^\circ C$

Versions <sup>(5)</sup>	Parameter	Notes	LH28F008SC-V85 <sup>(6)</sup>		LH28F008SC-V90 <sup>(7)</sup>		LH28F008SC-V120 <sup>(7)</sup>		Unit
			Min	Max	Min	Max	Min	Max	
$t_{AVAV}$	Write Cycle Time		85		90		120		ns
$t_{PHWL}$	RP# High Recovery to WE# Going Low	2	1		1		1		$\mu s$
$t_{ELWL}$	CE# Setup to WE# Going Low		10		10		10		ns
$t_{WLWH}$	WE# Pulse Width		40		40		40		ns
$t_{PHHWH}$	RP# $V_{HH}$ Setup to WE# Going High	2	100		100		100		ns
$t_{VPWH}$	$V_{PP}$ Setup to WE# Going High	2	100		100		100		ns
$t_{AVWH}$	Address Setup to WE# Going High	3	40		40		40		ns
$t_{DVWH}$	Data Setup to WE# Going High	3	40		40		40		ns
$t_{WHDY}$	Data Hold from WE# High		5		5		5		ns
$t_{WHAY}$	Address Hold from WE# High		5		5		5		ns
$t_{WHEH}$	CE# Hold from WE# High		10		10		10		ns
$t_{WHWH}$	WE# Pulse Width High		30		30		30		ns
$t_{WHRL}$	WE# High to RY/BY# Going Low			90		90		90	ns
$t_{WHGL}$	Write Recovery before Read		0		0		0		ns
$t_{QVVL}$	$V_{PP}$ Hold from Valid SRD, RY/BY# High	2,4	0		0		0		ns
$t_{QVPH}$	RP# $V_{HH}$ Hold from Valid SRD, RY/BY# High	2,4	0		0		0		ns

#### NOTES:

1. Read timing characteristics during block erase, byte write and lock-bit configuration operations are the same as during read-only operations. Refer to AC Characteristics for read-only operations.
2. Sampled, not 100% tested.
3. Refer to Table 4 for valid  $A_{IN}$  and  $D_{IN}$  for block erase, byte write, or lock-bit configuration.
4.  $V_{PP}$  should be held at  $V_{PPH1/2}$  (and if necessary RP# should be held at  $V_{HH}$ ) until determination of block erase, byte write, or lock-bit configuration success (SR.1/3/4/5=0).
5. See Ordering Information for device speeds (valid operational combinations).
6. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (High Seed Configuration) for testing characteristics.
7. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (Standard Configuration) for testing characteristics.

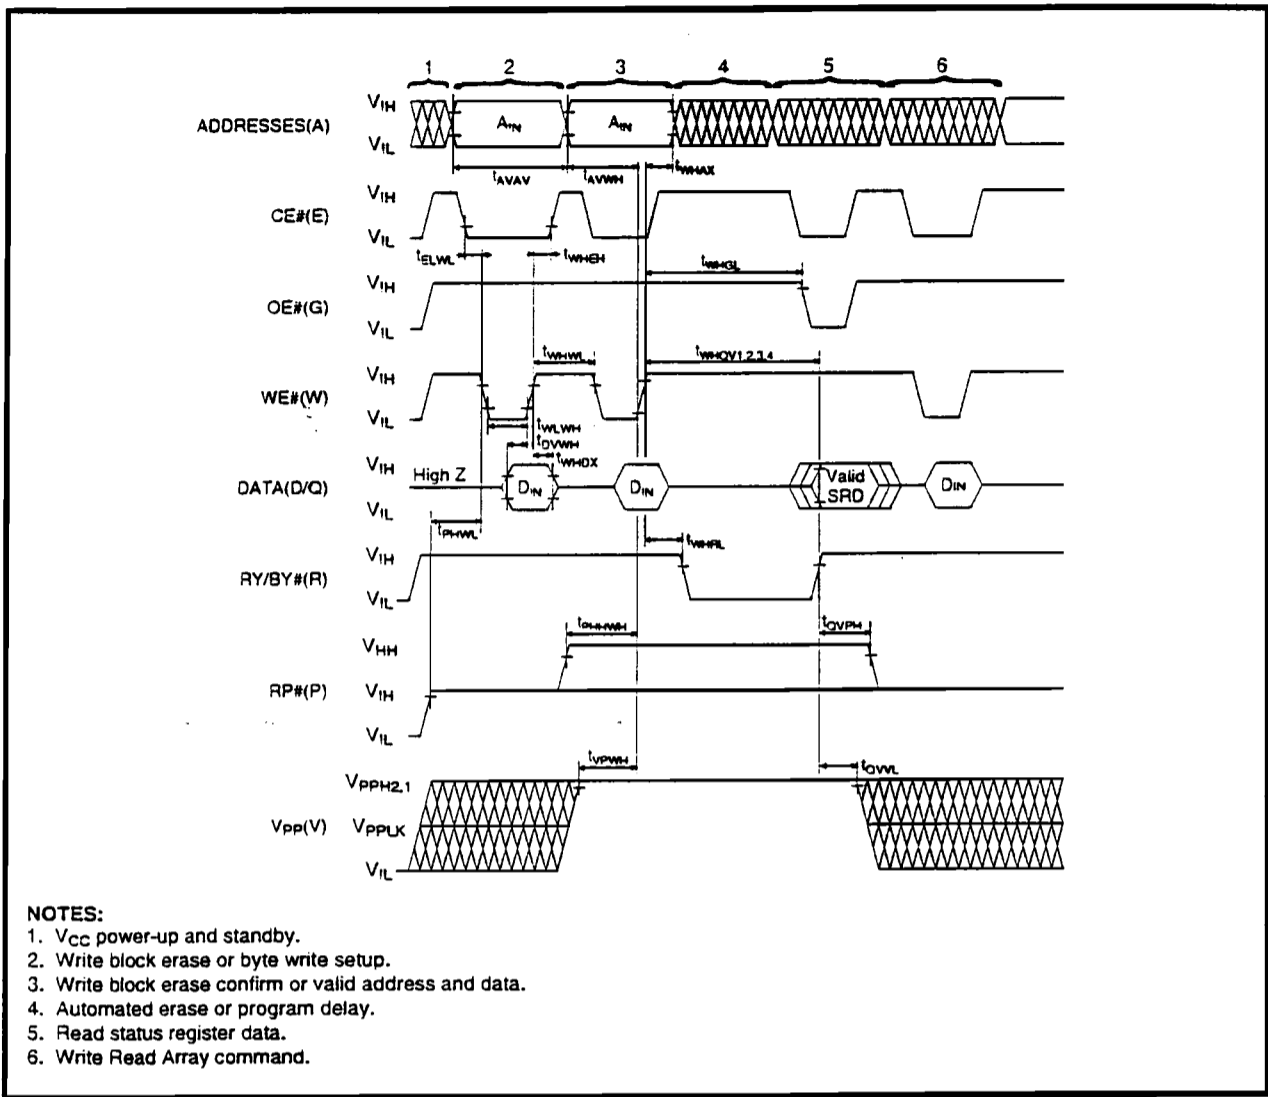

Figure 18. AC Waveform for WE#-Controlled Write Operations

### 6.2.6 ALTERNATIVE CE#-CONTROLLED WRITES<sup>(1)</sup>

$V_{CC}=5V\pm0.5V, 5V\pm0.25V, T_A=0^\circ C \text{ to } +70^\circ C$

Versions <sup>(5)</sup>	Parameter	Notes	LH28F008SC-V85 <sup>(6)</sup>		LH28F008SC-V90 <sup>(7)</sup>		LH28F008SC-V120 <sup>(7)</sup>		Unit
			Min	Max	Min	Max	Min	Max	
$t_{AVAV}$	Write Cycle Time		85		90		120		ns
$t_{PHEL}$	RP# High Recovery to CE# Going Low	2	1		1		1		$\mu s$
$t_{WLEI}$	WE# Setup to CE# Going Low		0		0		0		ns
$t_{LEEH}$	CE# Pulse Width		50		50		50		ns
$t_{PHHEH}$	RP# $V_{HH}$ Setup to CE# Going High	2	100		100		100		ns
$t_{VPEH}$	$V_{PP}$ Setup to CE# Going High	2	100		100		100		ns
$t_{AVEH}$	Address Setup to CE# Going High	3	40		40		40		ns
$t_{DVEH}$	Data Setup to CE# Going High	3	40		40		40		ns
$t_{EHDX}$	Data Hold from CE# High		5		5		5		ns
$t_{EHAX}$	Address Hold from CE# High		5		5		5		ns
$t_{EHWL}$	WE# Hold from CE# High		0		0		0		ns
$t_{EHEI}$	CE# Pulse Width High		25		25		25		ns
$t_{EHRI}$	CE# High to RY/BY# Going Low			90		90		90	ns
$t_{EHGL}$	Write Recovery before Read		0		0		0		ns
$t_{QVWL}$	$V_{PP}$ Hold from Valid SRD, RY/BY# High	2,4	0		0		0		ns
$t_{QVPH}$	RP# $V_{HH}$ Hold from Valid SRD, RY/BY# High	2,4	0		0		0		ns

#### NOTES:

1. In systems where CE# defines the write pulse width (within a longer WE# timing waveform), all setup, hold, and inactive WE# times should be measured relative to the CE# waveform.
2. Sampled, not 100% tested.
3. Refer to Table 4 for valid  $A_{IN}$  and  $D_{IN}$  for block erase, byte write, or lock-bit configuration.
4.  $V_{PP}$  should be held at  $V_{PPH1/2}$  (and if necessary RP# should be held at  $V_{HH}$ ) until determination of block erase, byte write, or lock-bit configuration success (SR.1/3/4/5=0).
5. See Ordering Information for device speeds (valid operational combinations).
6. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (High Seed Configuration) for testing characteristics.
7. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (Standard Configuration) for testing characteristics.

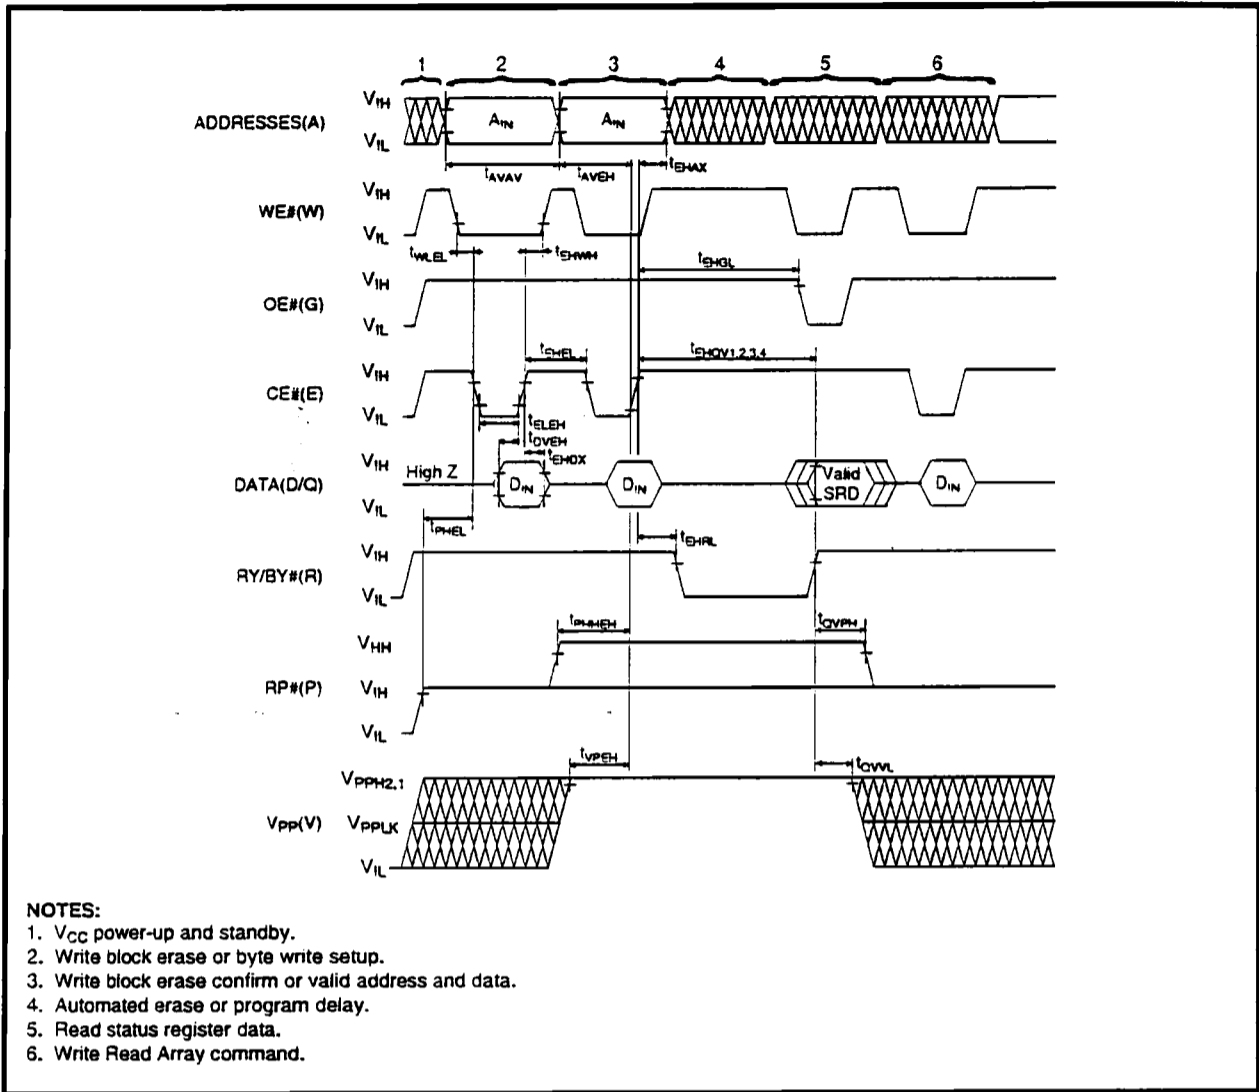

Figure 19. Alternate AC Waveform for CE#-Controlled Write Operations

## 6.2.7 RESET OPERATIONS

Figure 20. AC Waveform for Reset Operation

Reset AC Specifications<sup>(1)</sup>

Sym	Parameter	Notes	V <sub>CC</sub> =5V		Unit
			Min	Max	
t <sub>PLPH</sub>	RP# Pulse Low Time (If RP# is tied to V <sub>CC</sub> , this specification is not applicable)		100		ns
t <sub>PLRH</sub>	RP# Low to Reset during Block Erase, Byte Write, or Lock-Bit Configuration	2,3		12	μs
t <sub>svPH</sub>	V <sub>CC</sub> 4.5V to RP# High	4	100		ns

**NOTES:**

1. These specifications are valid for all product versions (packages and speeds).
2. If RP# is asserted while a block erase, byte write, or lock-bit configuration operation is not executing, the reset will complete within 100ns.
3. A reset time, t<sub>PHQV</sub>, is required from the latter of RY/BY# or RP# going high until outputs are valid.
4. When the device power-up, holding RP# low minimum 100ns is required after V<sub>CC</sub> has been in predefined range and also has been in stable there.

## LH28F008SC-V SmartVoltage Flash MEMORY

### 6.2.8 BLOCK ERASE, BYTE WRITE AND LOCK-BIT CONFIGURATION PERFORMANCE<sup>(3,4)</sup>

$V_{CC}=5V\pm0.5V, 5V\pm0.25V, T_A=0^{\circ}C \text{ to } +70^{\circ}C$

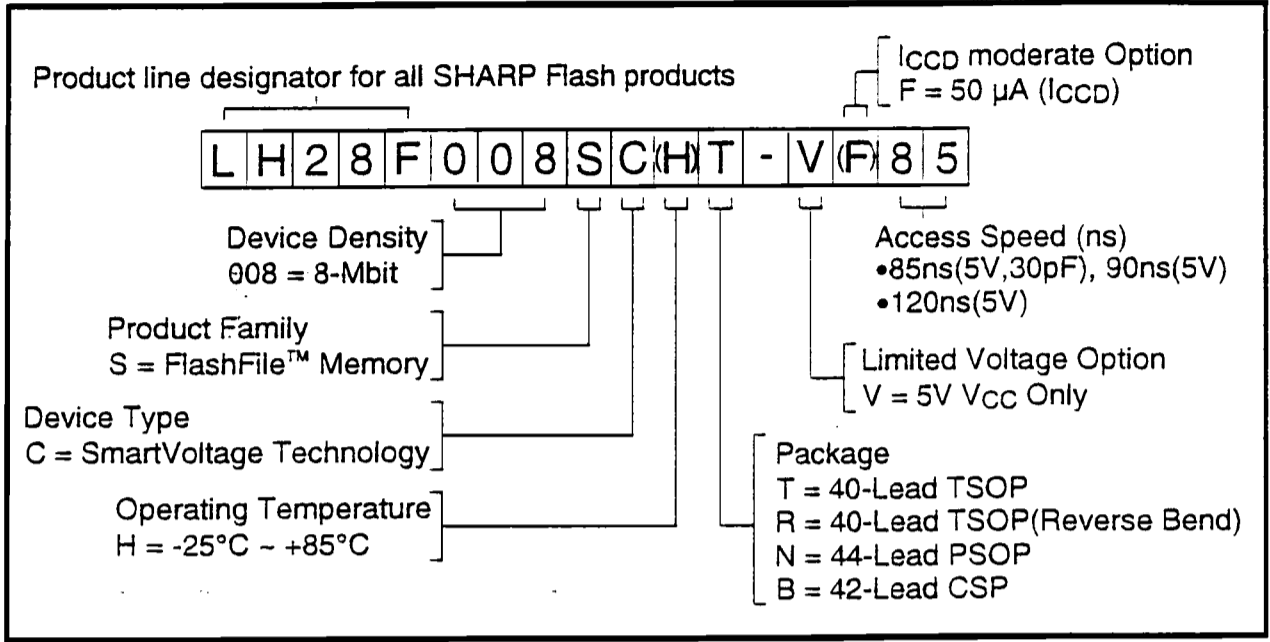

Sym	Parameter	Notes	$V_{pp}=5V$			$V_{pp}=12V$			Unit
			Min	Typ <sup>(1)</sup>	Max	Min	Typ <sup>(1)</sup>	Max	
$t_{WHQV1}$ $t_{EHQV1}$	Byte Write Time	2	6.5	8	TBD	4.8	6	TBD	$\mu s$
	Block Write Time	2	0.4	0.5	TBD	0.3	0.4	TBD	sec
$t_{WHQV2}$ $t_{EHQV2}$	Block Erase Time	2	0.9	1.1	TBD	0.3	1.0	TBD	sec
$t_{WHQV3}$ $t_{EHQV3}$	Set Lock-Bit Time	2	9.5	12	TBD	7.8	10	TBD	$\mu s$
$t_{WHQV4}$ $t_{EHQV4}$	Clear Block Lock-Bits Time	2	0.9	1.1	TBD	0.3	1.0	TBD	sec
$t_{WHRH1}$ $t_{EHRH1}$	Byte Write Suspend Latency Time to Read			5	6		4	5	$\mu s$
$t_{WHRH2}$ $t_{EHRH2}$	Erase Suspend Latency Time to Read			9.6	12		9.6	12	$\mu s$

**NOTES:**

1. Typical values measured at  $T_A=+25^{\circ}C$  and nominal voltages. Assumes corresponding lock-bits are not set. Subject to change based on device characterization.
2. Excludes system-level overhead.
3. These performance numbers are valid for all speed versions.
4. Sampled but not 100% tested.

## 7 ADDITIONAL INFORMATION

### 7.1 Ordering Information

Option	Order Code	Valid Operational Combinations	
		V <sub>CC</sub> =5.0±10% 100pF load, TTL I/O Levels	V <sub>CC</sub> =5.0±5% 30pF load, 1.5V I/O Levels
1	LH28F008SCX-V85	LH28F008SC-V90	LH28F008SC-V85
2	LH28F008SCX-V12	LH28F008SC-V120	

## 9600005. Block Locking and Unlocking

**PROBLEM:** The block locking and unlocking security feature is currently nonfunctional. Attempts to lock and unlock block may induce failure when executing a byte write or erase operation. The operations will fail because of a device protection error. The component incorrectly reads block lock-bit as being set when it is actually cleared.

**IMPLICATION:** Block locking feature is disabled. This erratum effects the following commands: Set Master Lock-Bit, Set Block Lock-Bits, and Clear Block Lock-Bits.

**WORKAROUND:** To prevent the accidental setting and clear of block lock-bits, SHARP sets the Master Lock-Bit during the test flow. Therefore device disables Lock-Bit operations even if RP# input is  $V_{IH}$ . (In this case, SR.1 and SR.4 will be set to "1".) Do not issue the Set Block Lock-Bit and Clear Block Lock-Bits command while 12V is applied to the RP# input. High voltage on RP# will override the Master Lock-Bit thereby enabling the lock-bit configuration command.

If data security is of utmost importance, lower  $V_{PP}$  voltage equal to or less than  $V_{PPLK}$  during normal operations. With  $V_{PP}$  equal to or less  $V_{PPLK}$ , the device is absolutely protected against all data manipulation operations.
