## High-Dynamic-Range, Direct Up-/Downconversion 1500MHz to 2500MHz Quadrature Mod/Demod

#### Abstract

General Description The MAX2023 low-noise, high-linearity, direct upconversion/downconversion quadrature modulator/demodulator is designed for single and multicarrier 1500 MHz to 2500 MHz DCS 1800/PCS 1900 EDGE, cdma2000®, WCDMA/LTE/TD-LTE, and PHS/PAS base-station applications. Direct conversion architectures are advantageous since they significantly reduce transmitter or receiver cost, part count, and power consumption as compared to traditional IF-based double-conversion systems. In addition to offering excellent linearity and noise performance, the MAX2023 also yields a high level of component integration. This device includes two matched passive mixers for modulating or demodulating in-phase and quadrature signals, two LO mixer amplifier drivers, and an LO quadrature splitter. On-chip baluns are also integrated to allow for single-ended RF and LO connections. As an added feature, the baseband inputs have been matched to allow for direct interfacing to the transmit DAC, thereby eliminating the need for costly I/Q buffer amplifiers. The MAX2023 operates from a single +5 V supply. It is available in a compact 36-pin TQFN package ( $6 \mathrm{~mm} x$ 6 mm ) with an exposed pad. Electrical performance is guaranteed over the extended $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

Features

- 1500 MHz to 2500 MHz RF Frequency Range
- Scalable Power: External Current-Setting Resistors Provide Option for Operating Device in Reduced-Power/Reduced-Performance Mode
- $36-\mathrm{Pin}, 6 \mathrm{~mm} \times 6 \mathrm{~mm}$ TQFN Provides High Isolation in a Small Package
Modulator Operation:
- Meets GSM Spurious Emission of -75dBc at 600 kHz Offset at Pout $=+6 \mathrm{dBm}$
- +23.5 dBm Typical OIP3
- +61dBm Typical OIP2
- +16dBm Typical OP1dB
- -54 dBm Typical LO Leakage
- 48 dBc Typical Sideband Suppression
- $-165 \mathrm{dBc} / \mathrm{Hz}$ Output Noise Density
- Broadband Baseband Input of 450 MHz Allows a Direct Launch DAC Interface, Eliminating the Need for Costly I/Q Buffer Amplifiers
- DC-Coupled Input Allows Ability for Offset Voltage Control
Demodulator Operation:
- +38 dBm Typical IIP3
- +59dBm Typical IIP2
- +30dBm Typical IP1dB
- 9.5dB Typical Conversion Loss
- 9.6dB Typical NF
- 0.025 dB Typical I/Q Gain Imbalance
- $0.56^{\circ}$ I/Q Typical Phase Imbalance

## High-Dynamic-Range, Direct Up-/Downconversion 1500MHz to 2500MHz Quadrature Mod/Demod

## ABSOLUTE MAXIMUM RATINGS

VCC_ to GND ......................................................-0.3V to +5.5 V
BBI+, BBI-, BBQ+, BBQ- to GND..................-4V to (VCC +0.3 V )
LO, RF to GND Maximum Current ...................................... 30 mA
RF Input Power .............................................................. 30 dBm

Baseband Differential I/Q Input Power ..........................+20dBm
LO Input Power............................................................. +10 dBm
RBIASLO1 Maximum Current ............................................. 10 mA
RBIASLO2 Maximum Current ............................................. 10 mA

| O3 Maximum | 10 mA |
| :---: | :---: |
| Continuous Power Dissipation (Note 1) | 7.6W |
| Operating Case Temperature Range (N | $+85^{\circ} \mathrm{C}$ |
| Maximum Junction Temperature ...... | $+150^{\circ} \mathrm{C}$ |
| Storage Temperature Range | $+150^{\circ} \mathrm{C}$ |
| Lead Temperature (soldering, 10s) | $+300^{\circ} \mathrm{C}$ |
| Soldering Temperature (reflow) | $+260^{\circ} \mathrm{C}$ |

Note 1: Based on junction temperature $T_{J}=T_{C}+\left(\theta_{J C} \times V_{C C} \times I_{C C}\right)$. This formula can be used when the temperature of the exposed pad is known while the device is soldered down to a PCB. See the Applications Information section for details. The junction temperature must not exceed $+150^{\circ} \mathrm{C}$.
Note 2: $T_{C}$ is the temperature on the exposed pad of the package. $T_{A}$ is the ambient temperature of the device and PCB.
Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## PACKAGE THERMAL CHARACTERISTICS

TQFN

Junction-to-Ambient
Thermal Resistance ( $\theta \mathrm{JA}$ ) (Notes 3, 4) ....................... $+34^{\circ} \mathrm{C} / \mathrm{W}$

Junction-to-Case
Thermal Resistance ( $\theta_{\mathrm{JC}}$ ) (Notes 1, 4) ...................... $+8.5^{\circ} \mathrm{C} / \mathrm{W}$

Note 3: Junction temperature $T_{J}=T_{A}+\left(\theta_{J A} \times V_{C C} \times I_{C C}\right)$. This formula can be used when the ambient temperature of the PCB is known. The junction temperature must not exceed $+150^{\circ} \mathrm{C}$.
Note 4: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a fourlayer board. For detailed information on package thermal considerations, refer to www.maxim-ic.com/thermal-tutorial.

## DC ELECTRICAL CHARACTERISTICS

(MAX2023 Typical Application Circuit, VCC $=4.75 \mathrm{~V}$ to 5.25 V , GND $=0 \mathrm{~V}$, I/Q inputs terminated into $50 \Omega$ to GND, LO input terminated into $50 \Omega$, RF output terminated into $50 \Omega$, OV common-mode input, R1 $=432 \Omega, \mathrm{R} 2=562 \Omega, \mathrm{R} 3=301 \Omega, \mathrm{~T} \mathrm{C}=-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$, unless otherwise noted. Typical values are at $\mathrm{V}_{\mathrm{CC}}=5 \mathrm{~V}, \mathrm{~T}_{\mathrm{C}}=+25^{\circ} \mathrm{C}$, unless otherwise noted.)

Note 5: Guaranteed by production test.
Note 6: Recommended functional range. Not production tested. Operation outside this range is possible, but with degraded performance of some parameters.
Note 7: $\quad V_{I / Q}=2.66 V_{P-P}$ differential $C W$ input.
Note 8: No baseband drive input. Measured with the baseband inputs terminated in $50 \Omega$. At low output power levels, the output noise density is equal to the thermal noise floor. See Output Noise Density vs. Output Power plots in Typical Operating Characteristics.
Note 9: The output noise vs. Pout curve has the slope of LO noise ( $\mathrm{Ln} \mathrm{dBc} / \mathrm{Hz}$ ) due to reciprocal mixing. Measured at 10 MHz offset from carrier.
Note 10: The LO noise ( $L=10(\operatorname{Ln} / 10)$ ), determined from the modulator measurements can be used to deduce the noise figure under-blocking at operating temperature (Tp in Kelvin), fBLOCK $=1+($ LCN - 1) Tp / To + LPBLOCK / (1000kTo), where TO $=290 \mathrm{~K}$, PBLOCK in $\mathrm{mW}, \mathrm{k}$ is Boltzmann's constant $=1.381 \times 10(-23) \mathrm{J} / \mathrm{K}$, and $\mathrm{LCN}=10\left(\mathrm{~L}_{\mathrm{C}} / 10\right)$, LC is the conversion loss. Noise figure underblocking in dB is NFBLOCK $=10 \times \log$ (fBLOCK). Refer to Application Note 3632.

Detailed Description
The MAX2023 is designed for upconverting differential in-phase (I) and quadrature (Q) inputs from baseband to a 1500 MHz to 2500 MHz RF frequency range. The device can also be used as a demodulator, downconverting an RF input signal directly to baseband. Applications include single and multicarrier 1500 MHz to 2500 MHz DCS/PCS EDGE, WCDMA/LTE/TD-LTE, cdma2000, and PHS/PAS base stations. Direct conversion architectures are advantageous since they significantly reduce transmitter or receiver cost, part count, and power consumption as compared to traditional IF-based double-conversion systems.
The MAX2023 integrates internal baluns, an LO buffer, a phase splitter, two LO driver amplifiers, two matched double-balanced passive mixers, and a wideband quadrature combiner. The MAX2023's high-linearity mixers, in conjunction with the part's precise in-phase and quadrature channel matching, enable the device to possess excellent dynamic range, $A C L R, 1 \mathrm{~dB}$ compression point, and LO and sideband suppression characteristics. These features make the MAX2023 ideal for single-carrier GSM and multicarrier WCDMA/LTE/TD-LTE operation.

## LO Input Balun, LO Buffer, and Phase Splitter

The MAX2023 requires a single-ended LO input, with a nominal power of 0 dBm . An internal low-loss balun at the LO input converts the single-ended LO signal to a differential signal at the LO buffer input. In addition, the internal balun matches the buffer's input impedance to $50 \Omega$ over the entire band of operation.
The output of the LO buffer goes through a phase splitter, which generates a second LO signal that is shifted by $90^{\circ}$ with respect to the original. The $0^{\circ}$ and $90^{\circ} \mathrm{LO}$ signals drive the I and Q mixers, respectively.

## LO Driver

Following the phase splitter, the $0^{\circ}$ and $90^{\circ} \mathrm{LO}$ signals are each amplified by a two-stage amplifier to drive the I and Q mixers. The amplifier boosts the level of the LO signals to compensate for any changes in LO drive levels. The two-stage LO amplifier allows a wide input power range for the LO drive. The MAX2023 can tolerate LO level swings from -3 dBm to +3 dBm .

# High-Dynamic-Range, Direct Up-/Downconversion 1500MHz to 2500MHz Quadrature Mod/Demod 

#### Abstract

I/Q Modulator The MAX2023 modulator is composed of a pair of matched double-balanced passive mixers and a balun. The I and Q differential baseband inputs accept signals from DC to 450 MHz with differential amplitudes up to 4VP-p. The wide input bandwidths allow operation of the MAX2023 as either a direct RF modulator or as an image-reject mixer. The wide common-mode compliance range allows for direct interface with the baseband DACs. No active buffer circuitry is required between the baseband DACs and the MAX2023 for wideband applications.

The I and Q signals directly modulate the $0^{\circ}$ and $90^{\circ} \mathrm{LO}$ signals and are upconverted to the RF frequency. The outputs of the I and Q mixers are combined through a balun to produce a singled-ended RF output.

## Applications Information

LO Input Drive
The LO input of the MAX2023 is internally matched to $50 \Omega$, and requires a single-ended drive at a 1500 MHz to 2500 MHz frequency range. An integrated balun converts the singled-ended input signal to a differential signal at the LO buffer differential input. An external DC-blocking capacitor is the only external part required at this interface. The LO input power should be within the -3 dBm to +3 dBm range. An LO input power of 0 dBm is recommended for best overall peformance.

Modulator Baseband I/Q Input Drive Drive the MAX2023 I and Q baseband inputs differentially for best performance. The baseband inputs have a $50 \Omega$ differential input impedance. The optimum source impedance for the I and Q inputs is $100 \Omega$ differential. This source impedance achieves the optimal signal transfer to the I and Q inputs, and the optimum output RF impedance match. The MAX2023 can accept input power levels of up to +20 dBm on the $I$ and $Q$ inputs. Operation with complex waveforms, such as CDMA carriers or GSM signals, utilize input power levels that are far lower. This lower power operation is made necessary by the high peak-to-average ratios of these complex waveforms. The peak signals must be kept below the compression level of the MAX2023.
The four baseband ports need some form of DC return to establish a common mode that the on-chip circuitry drives. This can be achieved by directly DC-coupling to the baseband ports (staying within the $\pm 3.5 \mathrm{~V}$ commonmode range), through an inductor to ground, or through a low-value resistor to ground.

## WCDMA/LTE/TD-LTE Transmitter <br> Applications

The MAX2023 is designed to interface directly with Maxim high-speed DACs. This generates an ideal total transmitter lineup, with minimal ancillary circuit elements required for widespread applications. Such DACs include the MAX5875 series of dual DACs, and the MAX5895 dual interpolating DAC. These DACs have ground-referenced differential current outputs. Typical termination of each DAC output into a $50 \Omega$ load resistor to ground, and a 10 mA nominal DC output current results in a 0.5 V common-mode DC level into the modulator I/Q inputs. The nominal signal level provided by the DACs will be in the -12 dBm range for a single CDMA or WCDMA carrier, reducing to -18 dBm per carrier for a four-carrier application.
The I/Q input bandwidth is greater than 450 MHz at -0.5 dB response. The direct connection of the DAC to the MAX2023 ensures the maximum signal fidelity, with no performance-limiting baseband amplifiers required. The DAC output can be passed through a lowpass filter to remove the image frequencies from the DAC's output response. The MAX5895 dual interpolating DAC can be operated at interpolation rates up to $\times 8$. This has the benefit of moving the DAC image frequencies to a very high, remote frequency, easing the design of the baseband filters. The DAC's output noise floor and interpolation filter

Figure 2. Complete Transmitter Lineup for GSM/EDGE DCS/PCS-Band Base Stations
stopband attenuation are sufficiently good to ensure that the 3GPP noise floor requirement is met for large frequency offsets, 60 MHz for example, with no filtering required on the RF output of the modulator.
Figure 1 illustrates the ease and efficiency of interfacing the MAX2023 with a Maxim DAC, in this case the MAX5895 dual 16-bit interpolating-modulating DAC.
The MAX5895 DAC has programmable gain and differential offset controls built in. These can be used to optimize the LO leakage and sideband suppression of the MAX2023 quadrature modulator.

## GSM Transmitter Applications

The MAX2023 is an ideal modulator for a zero-IF (ZIF), single-carrier GSM transmitter. The device's wide dynamic range enables a very efficient overall transmitter architecture. Figure 2 illustrates the exceptionally simple complete lineup for a high-performance GSM/EDGE transmitter.
The single-carrier GSM transmit lineup generates baseband I and Q signals from a simple 12-bit dual DAC such as the MAX5873. The DAC clock rate can be a multiple of the GSM system clock rate of 13 MHz . The ground-referenced outputs of the dual DAC are filtered by simple discrete element lowpass filters to attenuate both the DAC images and the noise floor. The I and Q baseband signals are then level shifted and amplified by a MAX4395 quad operational amplifier, configured as a differential input/output amplifier. This amplifier can deliver a baseband power level of greater than
+15dBm to the MAX2023, enabling very high RF output power levels. The MAX2023 will deliver up to +5 dBm for GSM vectors with full conformance to the required system specifications with large margins. The exceptionally low phase noise of the MAX2023 allows the circuit to meet the GSM system level noise requirements with no additional RF filters required, greatly simplifying the overall lineup.
The output of the MAX2023 drives a MAX2059 RF VGA, which can deliver up to +15 dBm of GSM carrier power and includes a very flexible digitally controlled attenuator with over 56dB of adjustment range. This accommodates the full static and dynamic power-control requirements, with extra range for lineup gain compensation.

## RF Output

The MAX2023 utilizes an internal passive mixer architecture that enables the device to possess an exceptionally low-output noise floor. With such architectures, the total output noise is typically a power summation of the theoretical thermal noise (kTB) and the noise contribution from the on-chip LO buffer circuitry. As demonstrated in the Typical Operating Characteristics, the MAX2023's output noise approaches the thermal limit of $-174 \mathrm{dBm} / \mathrm{Hz}$ for lower output power levels. As the output power increases, the noise level tracks the noise contribution from the LO buffer circuitry, which is approximately $-165 \mathrm{dBc} / \mathrm{Hz}$.

# High-Dynamic-Range, Direct Up-/Downconversion 1500MHz to 2500MHz Quadrature Mod/Demod 

The I/Q input power levels and the insertion loss of the device determine the RF output power level. The input power is a function of the delivered input I and $Q$ voltages to the internal $50 \Omega$ termination. For simple sinusoidal baseband signals, a level of 89 mVP -P differential on the $I$ and the $Q$ inputs results in a -17 dBm input power level delivered to the I and Q internal $50 \Omega$ terminations. This results in an RF output power of -26.6 dBm .

Figure 3. Diplexer Network Recommended for DCS 1800/
PCS 1900 EDGE Transmitter Applications

External Diplexer
LO leakage at the RF port can be nulled to a level less than -80 dBm by introducing DC offsets at the I and Q ports. However, this null at the RF port can be compromised by an improperly terminated I/Q IF interface. Care must be taken to match the I/Q ports to the driving DAC circuitry. Without matching, the LO's second-order (2fLO) term may leak back into the modulator's I/Q input port where it can mix with the internal LO signal to produce additional LO leakage at the RF output. This leakage effectively counteracts against the LO nulling. In addition, the LO signal reflected at the I/Q IF port produces a residual $D C$ term that can disturb the nulling condition.
As demonstrated in Figure 3, providing an RC termination on each of the I+, I-, Q+, Q- ports reduces the amount of LO leakage present at the RF port under varying temperature, LO frequency, and baseband termination conditions. See the Typical Operating Characteristics for details. Note that the resistor value is chosen to be $50 \Omega$ with a corner frequency $1 /(2 \pi R C)$ selected to adequately filter the fLO and 2fLO leakage, yet not affecting the flatness of the baseband response at the highest baseband frequency. The common-mode flo and 2 fLO signals at I+/I- and Q+/Q- effectively see the RC networks and thus become terminated in $25 \Omega(R / 2)$. The RC network provides a path for absorbing the 2flo and flo leakage, while the inductor provides high impedance at fLO and 2flo to help the diplexing process.

## RF Demodulator

The MAX2023 can also be used as an RF demodulator (see Figure 4), downconverting an RF input signal directly to baseband. The single-ended RF input accepts signals from 1500 MHz to 2500 MHz with power levels up to +30 dBm . The passive mixer architecture produces a conversion loss of typically 9.5 dB . The

Figure 4. MAX2023 Demodulator Configuration

## High-Dynamic-Range, Direct Up-/Downconversion 1500MHz to 2500MHz Quadrature Mod/Demod

downconverter is optimized for high linearity and excellent noise performance, typically with a +38 dBm IIP3, an input P1dB of +29.7 dBm , and a 9.6 dB noise figure.
A wide I/Q port bandwidth allows the port to be used as an image-reject mixer for downconversion to a quadrature IF frequency.
The RF and LO inputs are internally matched to $50 \Omega$. Thus, no matching components are required, and only DC-blocking capacitors are needed for interfacing.

## Demodulator Output Port Considerations

Much like in the modulator case, the four baseband ports require some form of DC return to establish a common mode that the on-chip circuitry drives. This can be achieved by directly DC-coupling to the baseband ports (staying within the $\pm 3.5 \mathrm{~V}$ common-mode range), through an inductor to ground, or through a
low-value resistor to ground. Figure 6 shows a typical network that would be used to connect to each baseband port for demodulator operation. This network provides a common-mode DC return, implements a high-frequency diplexer to terminate unwanted RF terms, and also provides an impedance transformation to a possible higher impedance baseband amplifier.
The network $C_{a}, R_{a}, L_{a}$, and $C_{b}$ form a highpass/lowpass network to terminate the high frequencies into a load while passing the desired lower IF frequencies. Elements $L_{a}, C_{b}, L_{b}, C_{c}, L_{c}$, and $C_{d}$ provide a possible impedance transformer. Depending on the impedance being transformed and the desired bandwidth, a fewer number of elements could be used. It is suggested that $\mathrm{La}_{\mathrm{a}}$ and $\mathrm{Cb}_{b}$ always be used since they are part of the high-frequency diplexer. If power matching is not a concern, then this would reduce the elements to just the diplexer.

Figure 5. Demodulator Combining Diagram

Figure 6. Baseband Port Typical Filtering and DC Return Network

# High-Dynamic-Range, Direct Up-/Downconversion 1500MHz to 2500MHz Quadrature Mod/Demod 

Resistor Rb provides a DC return to set the commonmode voltage. In this case, due to the on-chip circuitry, the voltage would be approximately OV DC. It can also be used to reduce the load impedance of the next stage. Inductor Ld can provide a bit of high-frequency gain peaking for wideband IF systems. Capacitor $\mathrm{C}_{e}$ is a DC block.
Typical values for $\mathrm{C}_{\mathrm{a}}, \mathrm{R}_{\mathrm{a}}, \mathrm{L}_{\mathrm{a}}$, and $\mathrm{C}_{\mathrm{b}}$ would be 1.5 pF , $50 \Omega, 11 \mathrm{nH}$, and 4.7 pF , respectively. These values can change depending on the LO, RF, and IF frequencies used. Resistor $\mathrm{Rb}_{\mathrm{b}}$ is in the $50 \Omega$ to $200 \Omega$ range.
The circuitry presented in Figure 6 does not allow for LO Leakage at RF port nulling. Depending on the LO at RF leakage requirement, a trim voltage might need to be introduced on the baseband ports to null the LO leakage.

## Power Scaling with Changes to the Bias Resistors

 Bias currents for the LO buffers are optimized by fine tuning resistors R1, R2, and R3. Maxim recommends using $\pm 1 \%$-tolerance resistors; however, standard $\pm 5 \%$ values can be used if the $\pm 1 \%$ components are not readily available. The resistor values shown in the Typical Application Circuit were chosen to provide peak performance for the entire 1500 MHz to 2300 MHz band. If desired, the current can be backed off from this nominal value by choosing different values for R1, R2, and R3. Contact the factory for additional details.
## Layout Considerations

A properly designed PCB is an essential part of any RF/microwave circuit. Keep RF signal lines as short as possible to reduce losses, radiation, and inductance. For the best performance, route the ground pin traces directly to the exposed pad under the package. The PCB exposed pad MUST be connected to the ground
plane of the PCB. It is suggested that multiple vias be used to connect this pad to the lower level ground planes. This method provides a good RF/thermal conduction path for the device. Solder the exposed pad on the bottom of the device package to the PCB. The MAX2023 evaluation kit can be used as a reference for board layout. Gerber files are available upon request at www.maxim-ic.com.

Power-Supply Bypassing
Proper voltage-supply bypassing is essential for highfrequency circuit stability. Bypass all VCC_ pins with 22 pF and $0.1 \mu \mathrm{~F}$ capacitors placed as close to the pins as possible, with the smallest capacitor placed closest to the device.
To achieve optimum performance, use good voltagesupply layout techniques. The MAX2023 has several RF processing stages that use the various VCC_ pins, and while they have on-chip decoupling, offchip interaction between them may degrade gain, linearity, carrier suppression, and output power-control range. Excessive coupling between stages may degrade stability.

Exposed Pad RF/Thermal Considerations The EP of the MAX2023's 36-pin TQFN-EP package provides a low thermal-resistance path to the die. It is important that the PCB on which the IC is mounted be designed to conduct heat from this contact. In addition, the EP provides a low-inductance RF ground path for the device.
The exposed pad (EP) MUST be soldered to a ground plane on the PCB either directly or through an array of plated via holes. An array of 9 vias, in a $3 \times 3$ array, is suggested. Soldering the pad to ground is critical for efficient heat transfer. Use a solid ground plane wherever possible.
