1. General Description

The F71869E which is the featured IO chip for PC system is equipped with one IEEE 1284 Parallel Port, two UART Ports, Hardware Keyboard Controller, SIR and one FDC. The F71869E integrates with hardware monitor, 9 sets of voltage sensor, 3 sets of creative auto-controlling fans and 3 temperature sensor pins for the accurate dual current type temperature measurement for CPU thermal diode or external transistors 2N3906. Others, the F71869E supports newest AMD TSI and Intel PECI 3.0 interfaces and INTEL Ibex PEAK SMBus for temperature sensing and provides the power sequence controller function for AMD platform

The F71869E provides flexible features for multi-directional application. For instance, the F71869E provides 45 GPIO pins (multi-pin), IRQ sharing function also designed in UART feature for particular usage and accurate current mode H/W monitor will be worth in measurement of temperature, provides 3 modes fan speed control mechanism included Manual Mode/Stage Auto Mode/Linear Auto Mode for users' selection.

A power saving function which is in order to save the current consumption when the system is in the soft off state is also integrated a power saving function. The power saving function supports that system boot-on not only by pressing the power button but also by the wake-up event. When the system enters the S4/S5 state, F71869E can cut off the VSB power rail which supplies power source to the devices like the LAN chip, the chipset, the SIO, the audio codec, DRAM, and etc. The PC system can be simulated to G3-like state when system enters the S4/S5 states. At the G3-like state, the F71869E consumes the 5VSB power rail only. The integrated two control pins are utilized to turn on or off VSB power rail in the G3-like status. The turned on VSB rail is supplied to a wake up device to fulfill a low power consumption system which supports a wake up function.

These features as above description will help you more and improve product value. Finally, the F71869E is powered by 3.3V voltage, with the LPC interface in the green package of 128-LQFP (14*14).

		0	FANCTLR3 is DAC mode. (Default)

5.2 Hardware Monitor

For the 8-bit ADC has the 8mv LSB, the maximum input voltage of the analog pin is 2.048V. Therefore the voltage under 2.048V (ex: 1.5V) can be directly connected to these analog inputs. The voltage higher than 2.048V should be reduced by a factor with external resistors so as to obtain the input range. Only 3VCC/VSB/VBAT is an exception for it is main power of the F71869E. Therefore 3VCC/VSB/VBAT can directly connect to this chip's power pin and need no external resistors. There are two functions in this pin with 3.3V. The first function is to supply internal analog power of the F71869E and the second function is that voltage with 3.3V is connected to internal serial resistors to monitor the +3.3V voltage. The internal serial resistors are two 150K ohm, so that the internal reduced voltage is half of +3.3V.

There are four voltage inputs in the F71869E and the voltage divided formula is shown as follows:

$$VIN = V_{+12V} \times \frac{R_2}{R_1 + R_2}$$ where V_{+12V} is the analog input voltage, for example.

If we choose R1=27K, R2=5.1K, the exact input voltage for V+12v will be 1.907V, which is within the tolerance. As for application circuit, it can be refer to the figure shown as follows.

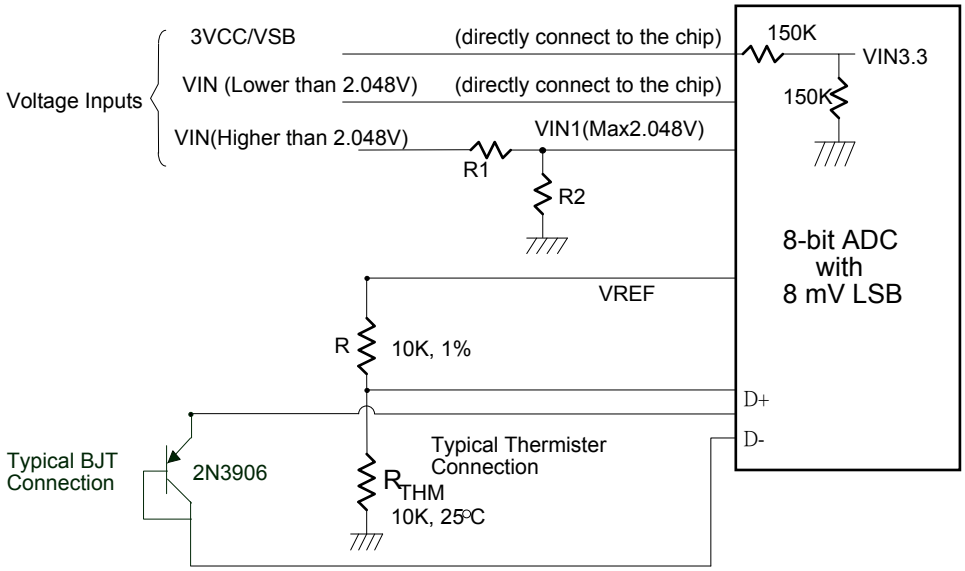

Figure 2. Hardware monitor configuration

The F71869E monitors three remote temperature sensors. These sensors can be measured from -40°C to 127°C. More detail please refer register description.

5.2.2 Monitor Temperature from "Thermistor"

The F71869E can connect three thermistors to measure environment temperature or remote temperature. The specification of thermistor should be considered to (1) β value is 3435K (2) resistor value is 10K ohm at 25°C. In the Figure 2, the thermistor is connected by a serial resistor with 10K ohm, then being connected to VREF.

5.2.3 Monitor Temperature from "Thermal diode"

Also, if the CPU, GPU or external circuits provide thermal diode for temperature measurement, the F71869E is capable to these situations. The build-in reference table is for PNP 2N3906 transistor. In the Figure 2, the transistor is directly connected into temperature pins.

5.2.4 ADC Noise Filtering

The ADC is integrating type with inherently good noise rejection. Micro-power operation places constraints on high-frequency noise rejection; therefore, careful PCB board layout and suitable external filtering are required for high-accuracy remote measurement in electronically noisy environment. High frequency EMI is best filtered at D+ and D- with an external 2200pF capacitor. Too high capacitance may introduce errors due to the rise time of the switched current source. Nearly all noise sources tested cause the ADC measurement to be higher than the actual temperature, depending on the frequency and amplitude.

5.2.5 Monitor Temperature from "SMBus device"

F71869E provides SMBus block read/write compatible Platform Control Hub (PCH) EC SMBus protocol, and provides byte read/write protocol to read CPU and chipset thermal temperature information. For byte read /write protocol, F71869E supports 4-suit device address to read or write from device information. For block read/write, F71869E support 1 suits device address and maximum

17 byte count for read protocol to read from device information, and 4 byte count for write protocol to write information to device.

5.2.6 Monitor Temperature from "PECI"

F71869E support Intel PECI1.1/PECI3.0/PECI_Request/PECI_Available interfaces to read temperature from PECI device.

5.2.7 Temperature OVT# Signal

There is a mode of temperature (t1 to t4) OVT function, and refer t1 to t4 temperature in the below Figure.

Over temperature event will trigger OVT# that shown as figure 3. In hysteresis mode, when monitored temperature exceeds the high temperature threshold value, OVT# will be asserted until the temperature goes below the hysteresis temperature.

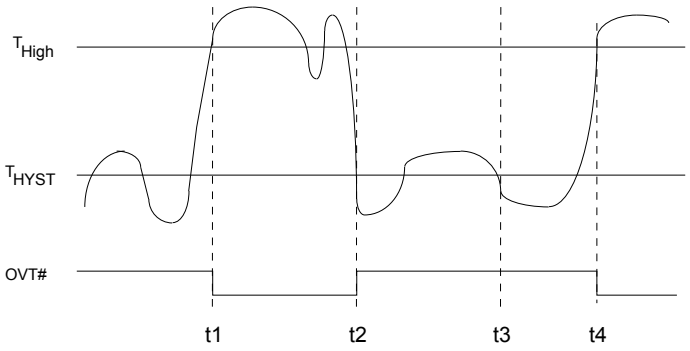

Figure 3

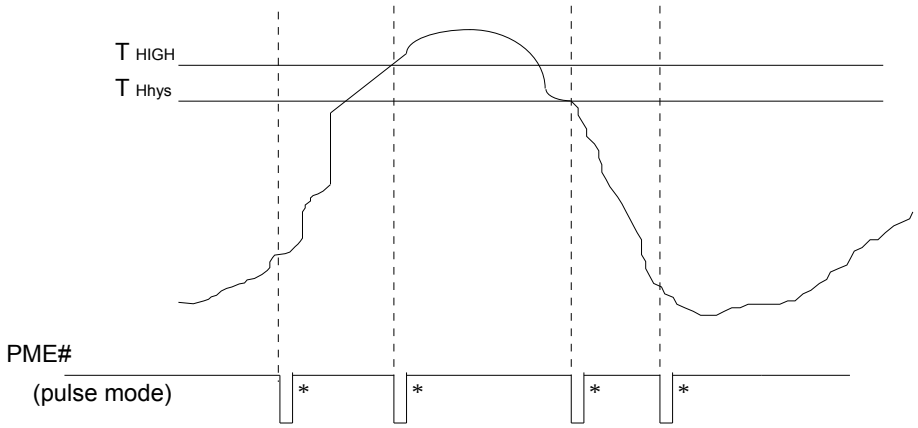
5.2.8 Temperature PME#

PME# interrupt for temperature is shown as figure 4. Temperature exceeding high limit (low limit) or going below high hysteresis (low hysteresis) will cause an interrupt if the previous interrupt has been reset by writing "1" all the interrupt Status Register.



*Interrupt Reset when Interrupt Status Registers are written 1

Figure 4 Hysteresis mode illustration

5.2.9 Fan Speed Count

Inputs are provided by the signals from fans equipped with tachometer outputs. The level of these signals should be set to TTL level, and maximum input voltage cannot be over 5V. If the input signals from the tachometer outputs are over the 5V, the external trimming circuit should be added to reduce the voltage to obtain the input specification.

Determine the fan counter according to:

$$\text{Count} = \frac{1.5 \times 10^6}{\text{RPM}}$$

In other words, the fan speed counter has been read from register, the fan speed can be evaluated by the following equation. As for fan, it would be best to use 2 pulses tachometer output per round.

$$\text{RPM} = \frac{1.5 \times 10^6}{\text{Count}}$$

As the register description of datasheet, the parameter “Count” register provides 12-bit resolution for RPM counting. In Fintek design, the value of parameter “Count” is from 4096 ~ 64 (5 bit filter). Therefore the RPM measure capability is from 366 ~ 23438 rpm.

Above example is for 2 pulses tachometer (Normal 4 Phases fan) output per round. If you use 8 Phases fan, means output 4 pulses per round. The RPM measure capability is from 183 ~ 11719 rpm.

5.2.10 Fan Speed Control

The F71869E provides 2 fan speed control methods: one is DAC FAN control and the other is PWM

duty cycle.

1. DAC Fan Control

The range of DC output is 0~3.3V, controlled by 8-bit register. 1 LSB is about 0.013V. The output DC voltage is amplified by external OP circuit, thus to reach maximum FAN OPERATION VOLTAGE, 12V. The output voltage will be given as followed:

$$\text{Output\_voltage (V)} = 3.3 \times \frac{\text{Programmed 8bit Register Value}}{255}$$

And the suggested application circuit for DAC fan control would be:

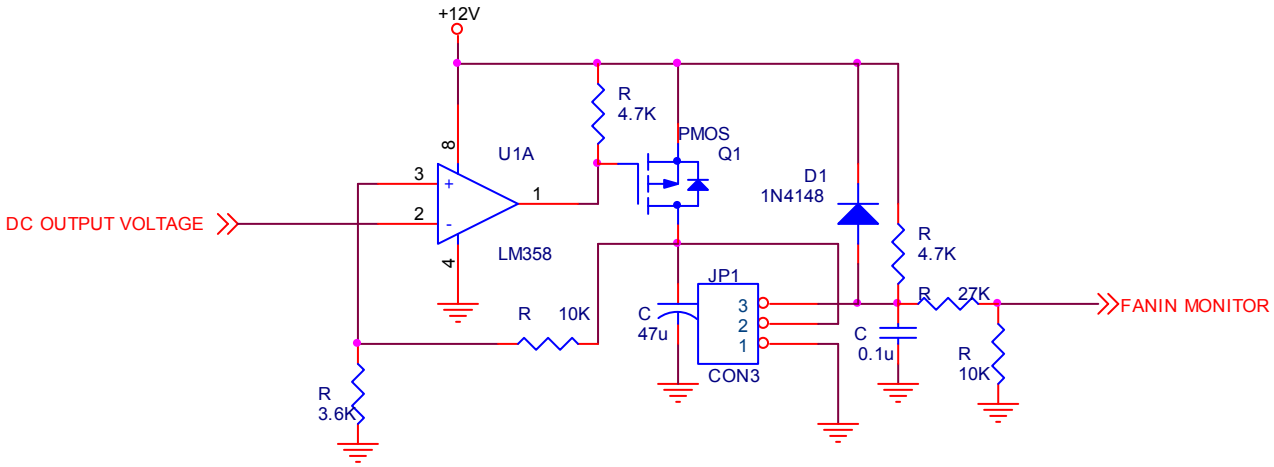


Figure 5 DAC fan control application circuit

2. PWM duty Fan Control

The duty cycle of PWM can be programmed by a 8-bit register. The default duty cycle is set to 100%, that is, the default 8-bit registers is set to FFh. The expression of duty can be represented as follows.

$$\text{Duty\_cycle(\%)} = \frac{\text{Programmed 8bit Register Value}}{255} \times 100\%$$

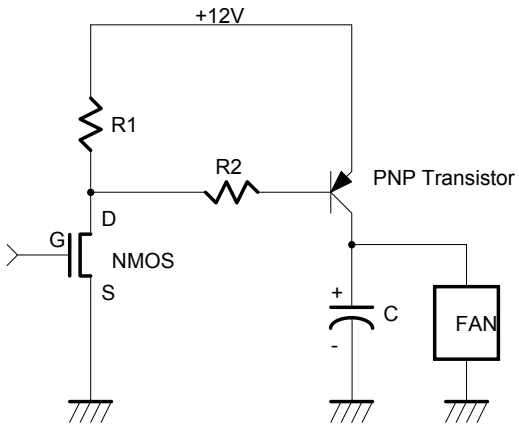

Figure 6 +12/5V PWM fan control application circuit

5.2.11 Fan Speed Control Mechanism

There are some modes to control fan speed and they are 1.Manual mode, 2.Stage auto mode 3. Linear auto mode. More detail, please refer the description of registers.

Each fan can be controlled by up to 8 kinds of temperature input. (1)D1+ temperature (2)D2+ temperature (3) D3+ temperature (4) PECI temperature (5) 4 suits SMBus master temperature. Please refer below structure diagram.

After the T0 ~T7 setting ready, select S1 ~ S4 temperature machine from T0 ~ T7, these 4-set temperature data are for maximum temperature comparison.

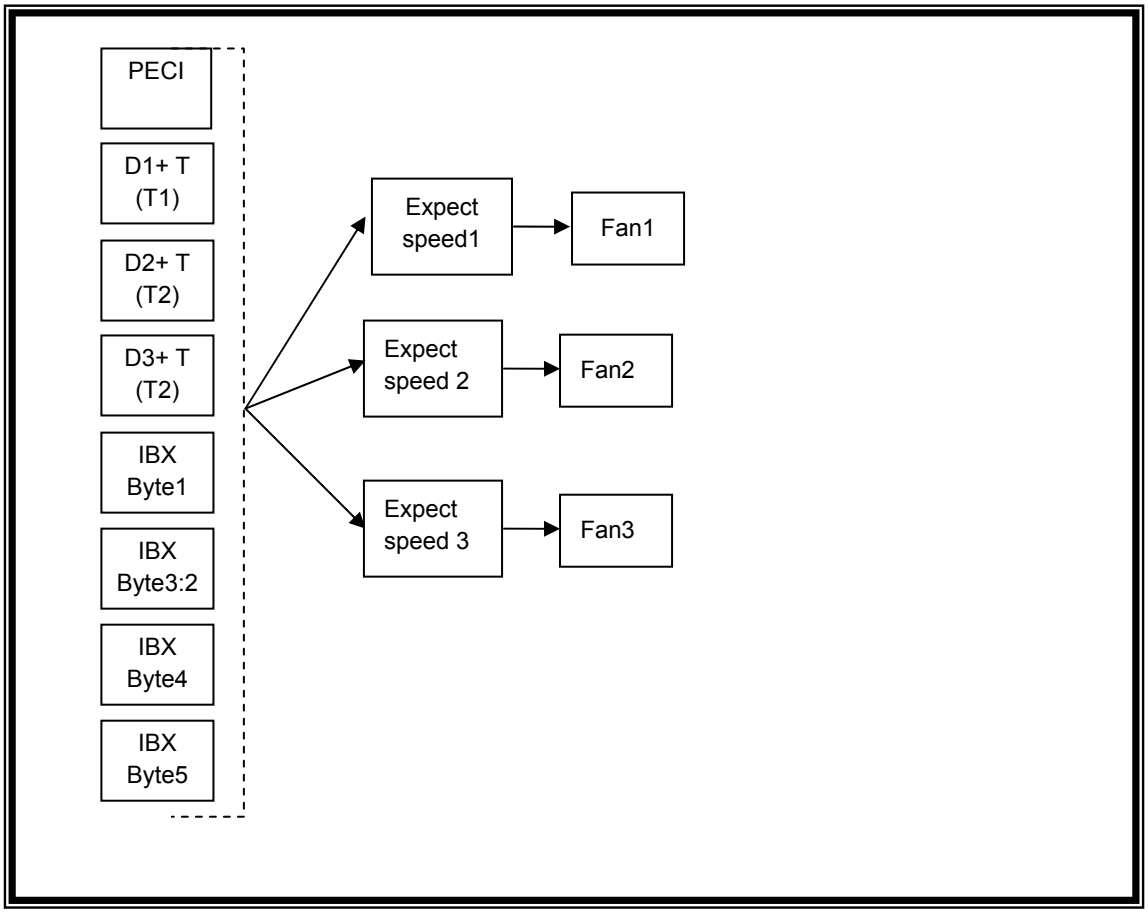

Figure 7 Relative temperature fan control

1. Manual mode

For manual mode, it generally acts as software fan speed control.

2. Stage auto mode

At this mode, the F71869E provides automatic fan speed control related to temperature variation of

CPU/GPU or the system. The F71869E can provide two temperature boundaries and three intervals, and each interval has its related fan speed PWM duty. All these values should be set by BIOS first. Take below figure as example. When temperature boundaries are set as 45 and 75°C and there are three intervals. The related desired fan speed for every interval is 40%, 80% and 100% (fixed). When the temperature is within 45~75'C, the fan speed will follow 80% PWM duty and that define in registers. It can be said that the fan will be turned on with a specific speed set by BIOS and automatically controlled with the temperature variation. The F71869E will take charge of all the fan speed control without software support.

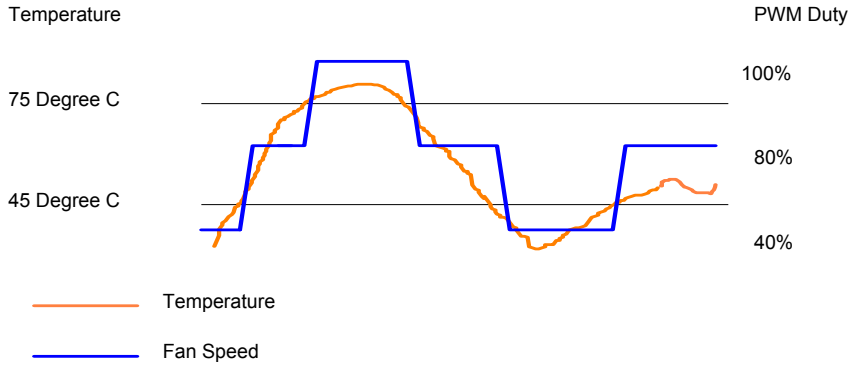

Figure 8 Stage mode fan control illustration-1

Below is a sample for Stage auto mode:
Set temperature as 60°C, 40°C and Duty as 100%, 70%, 50%

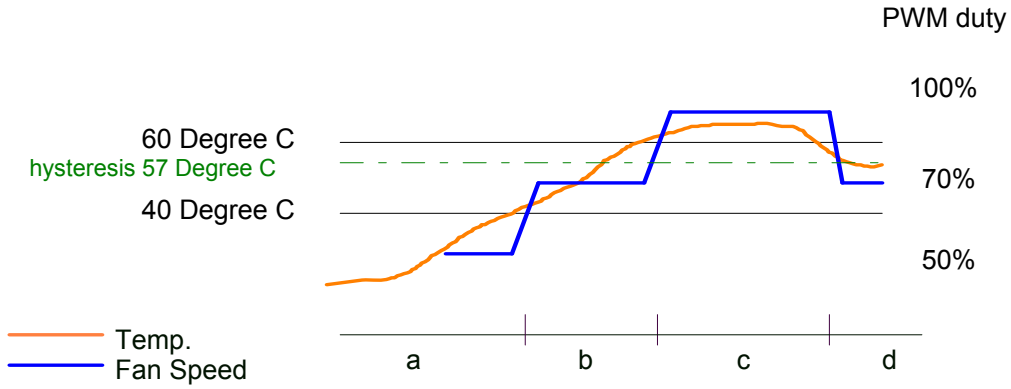

Figure 9 Stage mode fan control illustration-2

a. Once temp. is under 40°C, the lowest fan speed keeps 50% PWM duty
b. Once temp. is over 40°C,60°C, the fan speed will vary from 70% to 100% PWM duty and increase with temperature
c. Once temp. keeps in 55°C, fan speed keeps in 70% PWM duty
d. If set the hysteresis as 3°C (default 4°C), once temp reduces under 57°C, fan speed reduces to 70% PWM duty and stays there.

3. Linear auto mode

Otherwise, F71869E supports linear auto mode. Below has an example to describe this mode. More detail, please refer the register description.

Set temperature as 70°C, 40°C and Duty as 100%, 70%, 40%

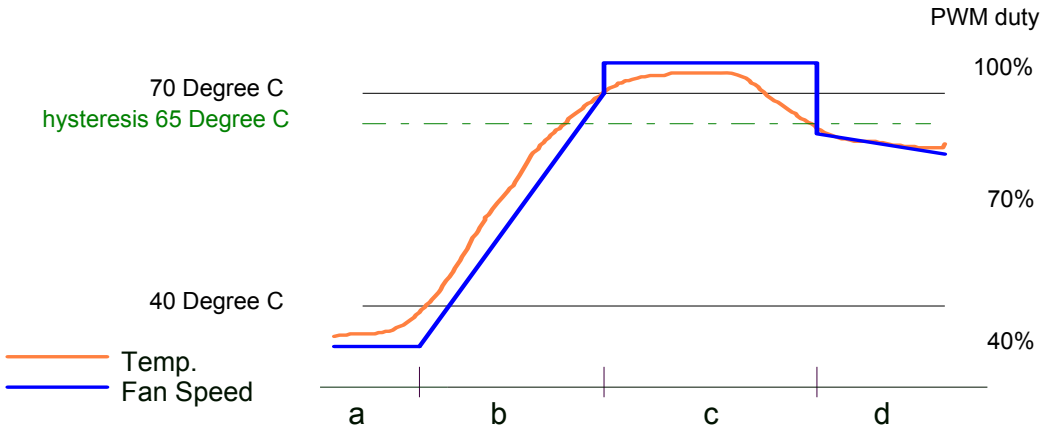

Figure 10 Linear mode fan control illustration

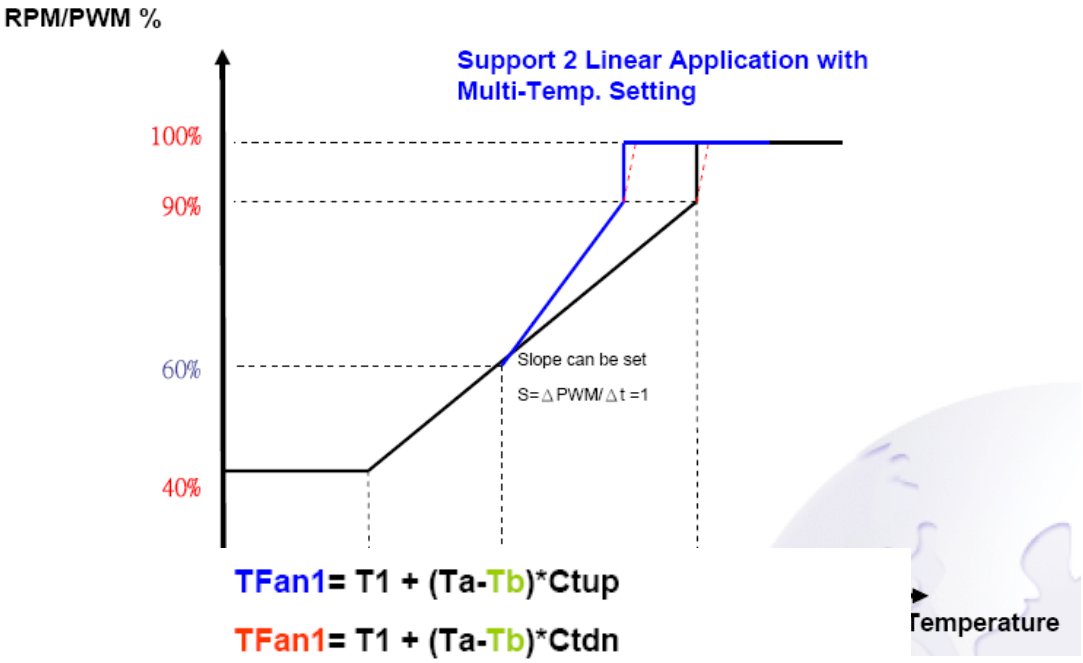
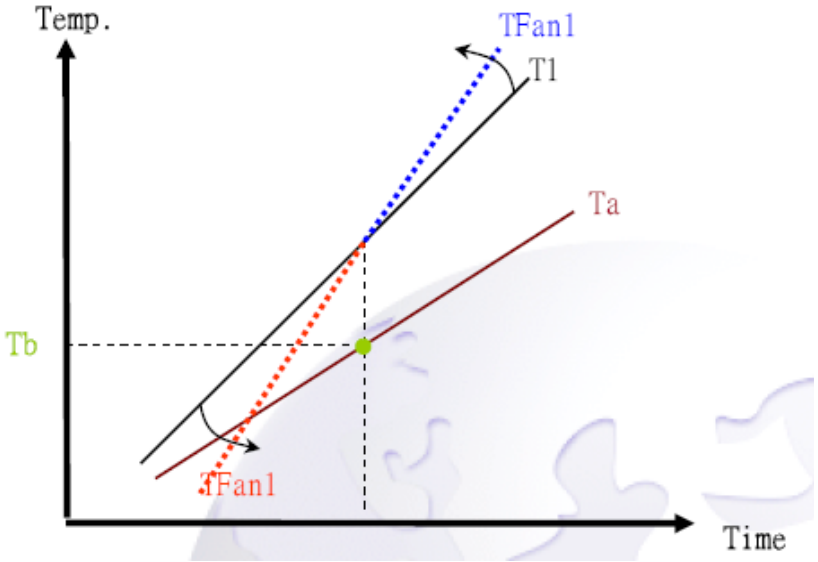
a. Once temp. is under 40°C, the lowest fan speed keeps 40% PWM duty
b. Once temp. is over 40°C and under 70°C, the fan speed will vary from 40% to 70% PWM duty and linearly increase with temp. variation. The temp.-fan speed monitoring and flash interval is 1sec.
c. Once temp. goes over 70°C, fan speed will directly increase to 100% PWM duty (full speed)
d. If set the hysteresis as 5°C (default is 4°C), once temp reduces under 65°C (not 70°C), fan speed reduces from 100% PWM duty and decrease linearly with temp..

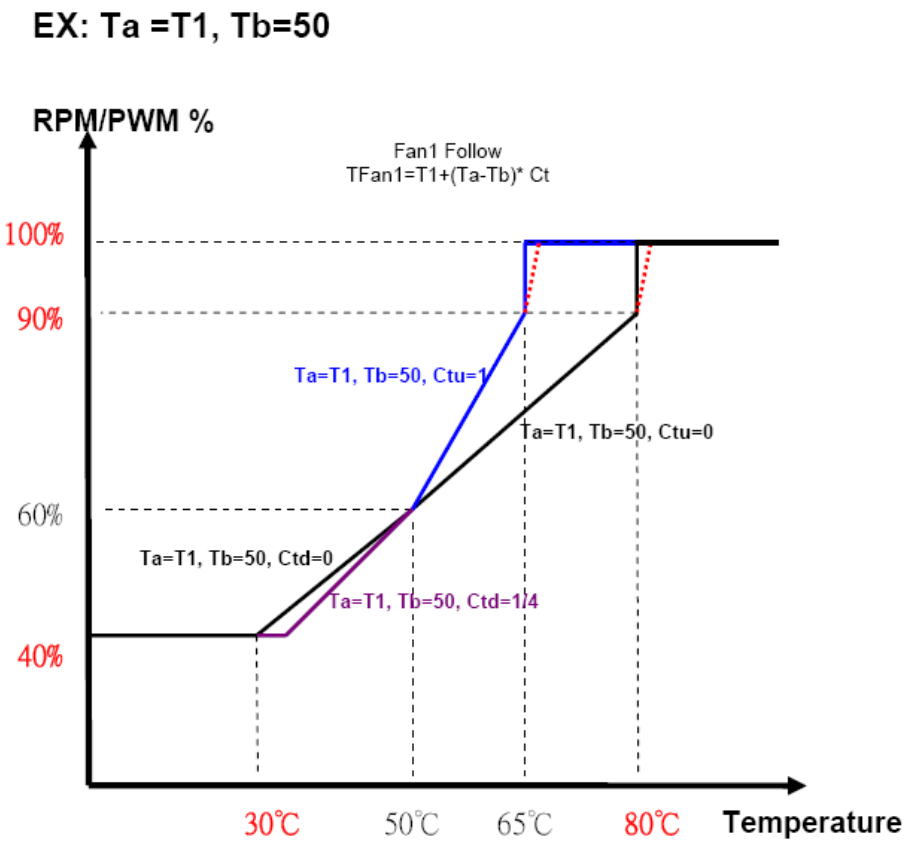
5.2.12 Fan Speed Control with Multi-temperature.

F71869E supports Multi-temperature for one Fan control. This function works with linear auto mode can extend two linear slopes for one Fan control. As below graph shows, this machine can support more silence fan control in low temperature and high fan speed in high temperature segment. More detail setting please refers the registers.



1. **Ctup**, **Ctdn** Can be Programmed to **1**, **½**, **¼**, **0**
2. **Ta** Can be Selected to the Same Temp. Source (Ex:T1)





5.2.13 FAN_FAULT#

Fan_Fault# will be asserted when the fan speed doesn't meet the expected fan speed within a programmable period (default is 11 seconds) or when fan stops with respect to PWM duty-cycle which should be able to turn on the fan. There are two conditions may cause the FAN_FAULT# event.

(1). When PWM_Duty reaches 0xFF, the fan speed count can't reach the fan expected count in time.

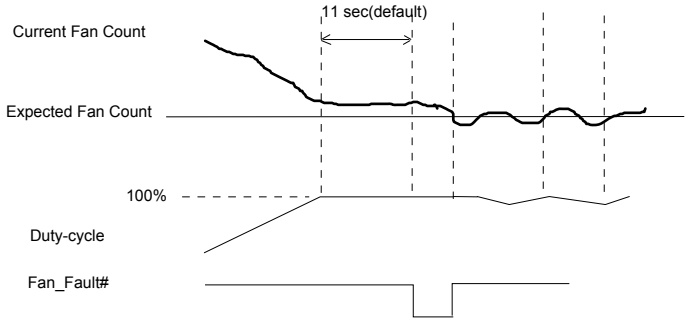


Figure 11 FAN_FAULT# event

(2). After the period of detecting fan full speed, PWM_Duty > Min. Duty, fan count is still in 0xFFF.

5.3 ACPI Function

The Advanced Configuration and Power Interface (ACPI) is a system for controlling the use of power in a computer. It lets computer manufacturer and user to determine the computer's power usage dynamically.

There are three ACPI states that are of primary concern to the system designer and they are designated S0, S3 and S5. S0 is a full-power state; the computer is being actively used in this state. The other two are called sleep states and reflect different power consumption when power-down. S3 is a state that the processor is powered down but the last procedural state is being stored in memory which is still active. S5 is a state that memory is off and the last procedural state of the processor has been stored to the hard disk. Take S3 and S5 as comparison, since memory is fast, the computer can quickly come back to full-power state, the disk is slower than the memory and the computer takes longer time to come back to full-power state. However, since the memory is off, S5 draws the minimal power comparing to S0 and S3.

It is anticipated that only the following state transitions may happen:

S0→S3, S0→S5, S5→S0, S3→S0 and S3→S5.

Among them, S3→S5 is illegal transition and won't be allowed by state machine. It is necessary to enter S0 first in order to get to S5 from S3. As for transition S5→S3 will occur only as an immediate state during state transition from S5→S0. It isn't allowed in the normal state transition.

The below diagram described the timing, the always on and always off, keep last state could be set in control register. In keep last state mode, one register will keep the status of before power loss. If it is power on before power loss, it will remain power on when power is resumed, otherwise, if it is power off before power loss, it will remain power off when power is resumed.

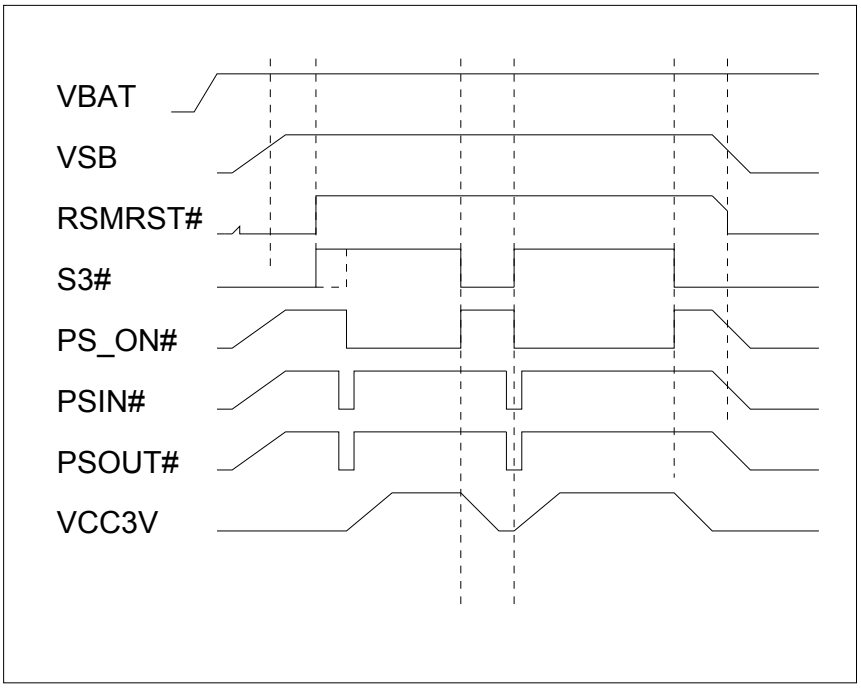

Figure 12 Default timing: Always off

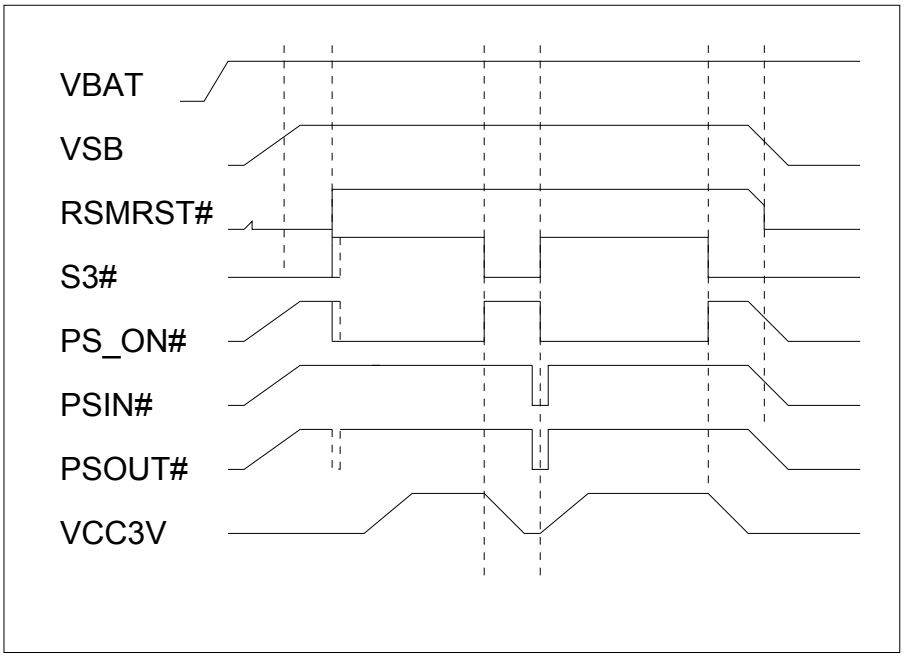

Figure 13 Optional timing: Always on

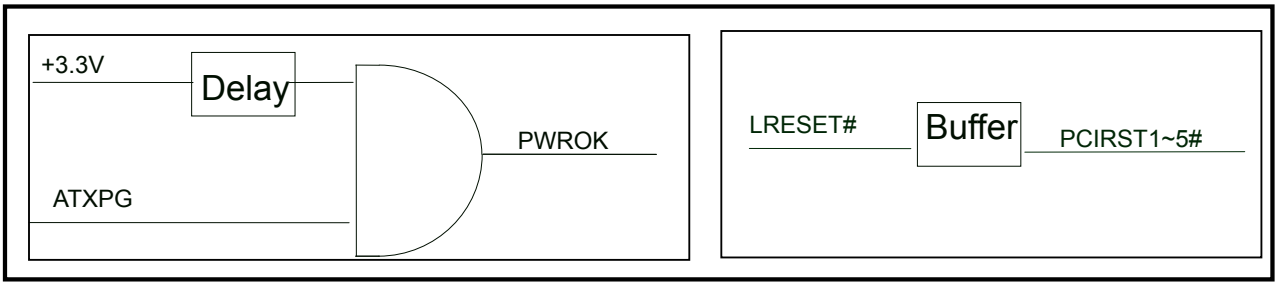
PCI Reset and PWROK Signals

The F71869E supports 5 output buffers for 5 reset signals.



So far as the PWROK issue is as the figure above. PWROK is delayed 400ms (default) as VCC arrives 2.8V, and the delay timing can be programmed by register. An additional delay could be added to PWROK (0ms, 100ms, 200ms and 400ms). If RSTCION# and PCIRST4#/PCIRST5# are enabled, RSTCON# could be programmed to be asserted via PWROK or PCIRST4#/PCIRST5#.

5.4 Power Timing Control Sequence

The F71869E offers 4 timing pins which are designed for AMD platform power sequence control including VDIMM, VDDA, Vcore, and VLDT (default) or other timing application purposes. All the timings on/off are relative to S3#/S5# and can be programmed by the register 0x0AF7. As shown in the below figure, the default timings of TIMING_1~4 are displayed in blue lines, and all the timings are enabled in the S0 state except TIMING_1. However, TIMING_2~4 can be programmed to enable in the S3 state, and TIMING_1 can also be programmed to disable in the S3 state, like the dotted blue line shown in the figure below.

VDDOK_D400 is the PWROK delay timing from VDD3VOK. The default setting is that delay 400ms, there are 100ms, 200ms, and 300ms for option. It can be set in the register 0x0AF5.

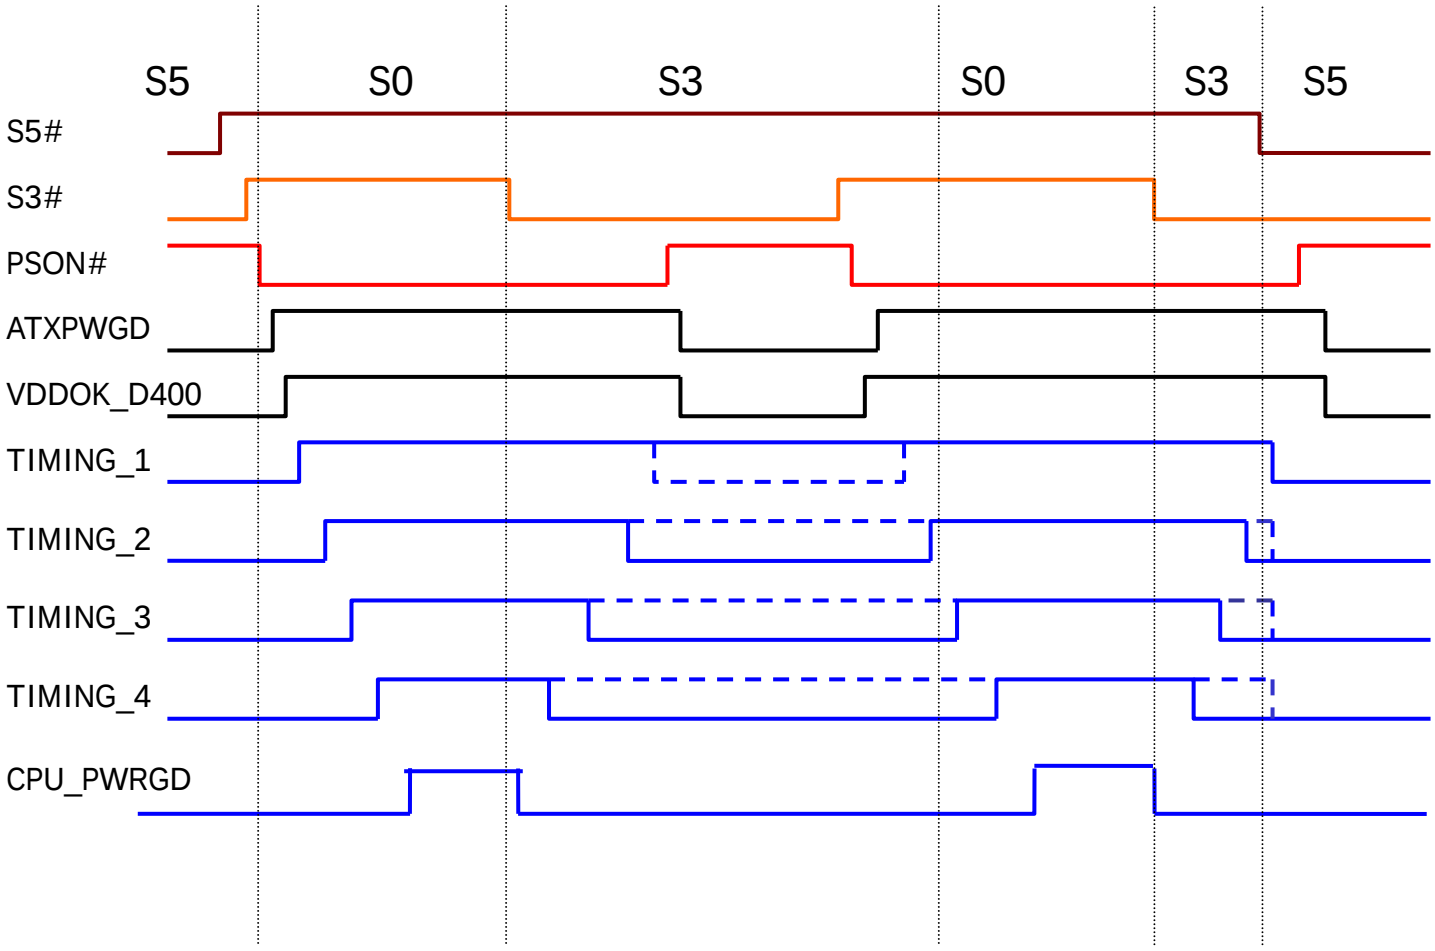


Figure 14 Timing on/off sequence

5.5 ST1, ST2 and ATX_PWRGDSW Timing

The F71869E provides three additional timing switching pins which are named as ST1, ST2 and ATXPWRGDSW. They can be applied in the certain applications about power switch which depends on the ACPI states. The detail timing can be referred in the following diagrams. The default timing of ATX_PWRGDSW in the S5 state is low, but it can be programmed high by the register 0x0AF6.

5.6 AMD TSI and Intel PECI 3.0 Function

The F71869E provides Intel PECI/AMD TSI interfaces for new generational CPU temperature sensing. In AMDSI interface, there are SIC and SID signals for temperature information reading from AMD CPU. The SIC signal is for clocking use, the other is for data transferring. More details, please refer register description.

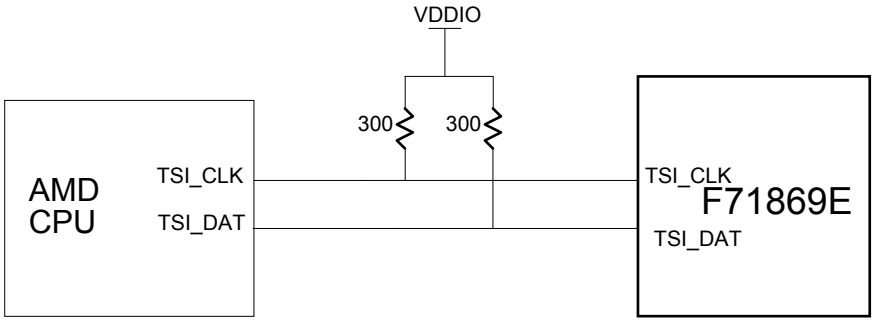

Figure 17 AMD TSI typical application

In Intel PECI interface, the F71869E can connect to CPU directly. The F71869E can read the temperature data from CPU, than the fan control machine of F71869E can implement the Fan to cool down CPU temperature. The application circuit is as below.

5.7 EUP Power Saving Function

The two pins, CTRL0# and CTRL1#, which control the standby power rail on/off to fulfill the purpose which decreases the power consumption when the system in the sleep state or the soft-off state. These two pins connected to the external PMOSs and the defaults are high in the sleep state in order to cut off all the standby power rails to save the power consumption. If the system needs to support wake-up function, the two pins can be programmable to set which power rail is turned on. The programmable register is powered by battery. So, the setting is kept even the AC power is lost when the register is set. At the power saving state (FINTEK calls it G3-like state), the F71869E consumes 5VSB power rail only to realize a low power consumption system. Below is EuP function's timing graphs.

6. Register Description

The configuration register is used to control the behavior of the corresponding devices. To configure the register, using the index port to select the index and then writing data port to alter the parameters. The default index port and data port are 0x4E and 0x4F respectively. Pull down the SOUT1 pin to change the default value to 0x2E/0x2F. To enable configuration, the entry key 0x87 must be written to the index port. To disable configuration, write exit key 0xAA to the index port. Following is a example to enable configuration and disable configuration by using debug.

-o 4e 87
-o 4e 87 (enable configuration)
-o 4e aa (disable configuration)

The Following is a register map (total devices) grouped in hexadecimal address order, which shows a summary of all registers and their default value. Please refer each device chapter if you want more detail information.
