About This Book

This datasheet describes the IBM PowerNP NP4GS3 and explains the basics of building a system using it.

A terms and abbreviations list is provided in *Section 15. Glossary of Terms and Abbreviations* on page 539.

Who Should Read This Manual

This datasheet provides information for network hardware engineers and programmers using the NP4GS3 to develop interconnect solutions for Internet or enterprise network providers. It includes an overview of data flow through the device and descriptions of each functional block. In addition, it provides electrical, physical, thermal, and configuration information about the device.

Conventions Used in This Manual

The following conventions are used in this manual.

1. The bit notation in the following sections is non-IBM, meaning that bit zero is the least significant bit and bit 31 is the most significant bit in a 4-byte word.
   - *Section 2. Physical Description*
   - *Section 3. Physical MAC Multiplexer*
   - *Section 4. Ingress Enqueuer / Dequeuer / Scheduler*
   - *Section 5. Switch Interface*
   - *Section 6. Egress Enqueuer / Dequeuer / Scheduler*
   - *Section 7. Embedded Processor Complex*
   - *Section 9. Serial / Parallel Manager Interface*
2. The bit notation in *Section 8. Tree Search Engine* and *Section 10. Embedded PowerPC™ Subsystem* is IBM-standard, meaning that bit 31 is the least significant bit and bit zero is the most significant bit in a 4-byte word.
3. Nibble numbering is the same as byte numbering. The left-most nibble is most significant and starts at zero.
4. All counters wrap back to zero when they exceed their maximum values. Exceptions to this rule are noted in the counter definitions.
5. Overbars ($\overline{\text{TxEnb}}$, for example) designate signals that are asserted "low."

6. Numeric notation is as follows:
   - Hexadecimal values are preceded by x or X. For example: x‘0B00’.
   - Binary values in text are either spelled out (zero and one) or appear in quotation marks. For example: ‘10101’.
   - Binary values in the Default and Description columns of the register sections are often isolated from text as in this example:
     0: No action on read access
     1: Auto-reset interrupt request register upon read access
7. Field length conventions are as follows:
   - 1 byte = 8 bits
   - 1 word = 4 bytes
   - 1 double word (DW) = 2 words = 8 bytes
   - 1 quadword (QW) = 4 words = 16 bytes
8. For signal and field definitions, when a field is designated as “Reserved”:
   - It must be sent as zero as an input into the NP4GS3, either as a signal I/O or a value in a reserved field of a control block used as input to a picocode process.
   - It must not be checked or modified as an output from the NP4GS3, either as a signal I/O or a value in a reserved field of a control block used as input to an external code process.
   - Its use as code point results in unpredictable behavior.

1. General Information

1.1 Features

- 4.5 million packets per second (Mpps) Layer 2 and Layer 3 switching.
- Eight dyadic protocol processor units (DPPUs)
  - Two picocode processors per DPPU
  - Nine shared coprocessors per DPPU
  - Four threads per DPPU
  - Zero context switching overhead between threads
- Embedded PowerPC™ processor and external 33/66 MHz 32-bit PCI Bus for enhanced design flexibility.
  - supports RISCWatch through the JTAG interface
- Ten medium access controls (MACs)
  - Up to four Gigabit Ethernet or 40 Fast Ethernet ports, accessed through Serial Media-Independent (SMII), Gigabit Media-Independent (GMII), and Ten-Bit (TBI) interfaces, that support industry standard physical layer devices
  - 36 Ethernet statistics counters per MAC
  - Up to one million software-defined, hardware-assisted counters, enabling support of many standard Management Information Bases (MIBs) at wire speed
  - 16 OC-3c, 4 OC-12, 4 OC-12c, 1 OC-48, or 1 OC-48c integrated packet over SONET (POS) interfaces that support industry standard POS framers
  - Hardware VLAN support (detection, tag insertion and deletion).
- Two data-aligned synchronous link (DASL) ports
  - Attach the device to an IBM Packet Routing Switch, another NP4GS3, or to itself.
  - Rated 3.25 to 4 Gigabits per second (Gbps)
  - Compliant with the EIA/JEDEC JESD8-6 standard for differential HSTL
- Addressing capability of 64 target network processors, enabling the design of network systems with up to 1024 ports.
- Advanced flow control mechanisms that tolerate high rates of temporary oversubscription without TCP collapse.
- Fast lookups and powerful search engines based on geometric hash functions that yield lower collision rates than conventional bit-scrambling methods.
- Hardware support for port mirroring[1]. Mirrored traffic can share bandwidth with user traffic or use a separate switch data path, eliminating the normal penalty for port mirroring.
- Support for jumbo frames (9018 without VLAN, 9022 with VLAN).
- Hardware-managed, software-configured bandwidth allocation control of 2047 concurrent communication flows.
- Serial management interface to support physical layer devices, board, and box functions
- IBM SA-27E, 0.18 μm technology.
- Voltage ratings:
  - 1.8 V supply voltage
  - 2.5 V and 3.3 V compatibility with drivers and receivers
  - 1.25 V reference voltage for SSTL drivers
  - 1.5 V compatibility for DASL interfaces
- 1088-pin Bottom Surface Metallurgy - Ceramic Column Grid Array (BSM-CCGA) package with 815 Signal I/O.
- IEEE 1149.1a JTAG compliant.

1. OC-48c ports are not supported by port mirroring functions.

1.2 Ordering Information

Part Number	Description
IBM32NPR161EPXCAD133	IBM PowerNP NP4GS3A (R1.1)
IBM32NPR161EPXCAE133	IBM PowerNP NP4GS3B (R2.0)

1.3 Overview

The IBM PowerNP™ NP4GS3 network processor enables network hardware designers to create fast, powerful, and scalable systems. The NP4GS3 contains an Embedded Processor Complex (EPC) in which processors and coprocessors work with hardware accelerators to increase processing speed and power. Additional features, such as integrated search engines, variable packet length schedulers, and support for QoS functions, support the needs of customers who require high function, high capacity, media-rate switching. The NP4GS3 is also highly scalable, capable of supporting systems with up to 1024 ports.

The EPC is the heart of the NP4GS3, evaluating, defining, and processing data. It maximizes the speed and processing power of the device and provides it with functionality above that of an independent switching device. Within the EPC, eight dyadic protocol processor units (DPPUs) combine picocode processors, coprocessors, and hardware accelerators to support functions such as high-speed pattern search, data manipulation, internal chip management, frame parsing, and data prefetching.

The NP4GS3 provides fast switching by integrating switching engine, search engine, and security functions on one device. It supports Layer 2 and 3 Ethernet frame switching, and includes three switch priority levels for port mirroring, high priority user frames, and low priority frames. It supports Ethernet, packet over SONET (POS), and Point-to-Point Protocol (PPP) protocols. Because of the device's ability to enforce hundreds of rules with complex range and action specifications, NP4GS3-based systems are uniquely suited for server clusters.

NP4GS3-based systems can range from a desktop system with a single device to multi-rack systems with up to 64 network processors. Scaling of this nature is accomplished through the use of IBM's high performance, non-blocking, packet switching technology and IBM's data-aligned synchronous link (DASL) interface, which can be adapted to other switch technologies. Using the NP4GS3 with the IBM Packet Routing Switch enables addressing of up to 640 ports. Third-party switches can address up to 1024 ports.

Systems developed with the NP4GS3 use a distributed software model. To support this model, the device hardware and Code Development Suite include on-chip debugger facilities, a picocode assembler, and a picocode and system simulator, all of which can decrease the time to market for new applications.

In order to take advantage of these features, a designer must know how the device works and how it fits into a system. The following sections discuss the basic placement of the device within a system, its major functional blocks, and the movement of data through it. The chapters following this overview explore all of these issues in detail.

1.4 NP4GS3-Based Systems

The NP4GS3 is scalable, enabling multiple system configurations:

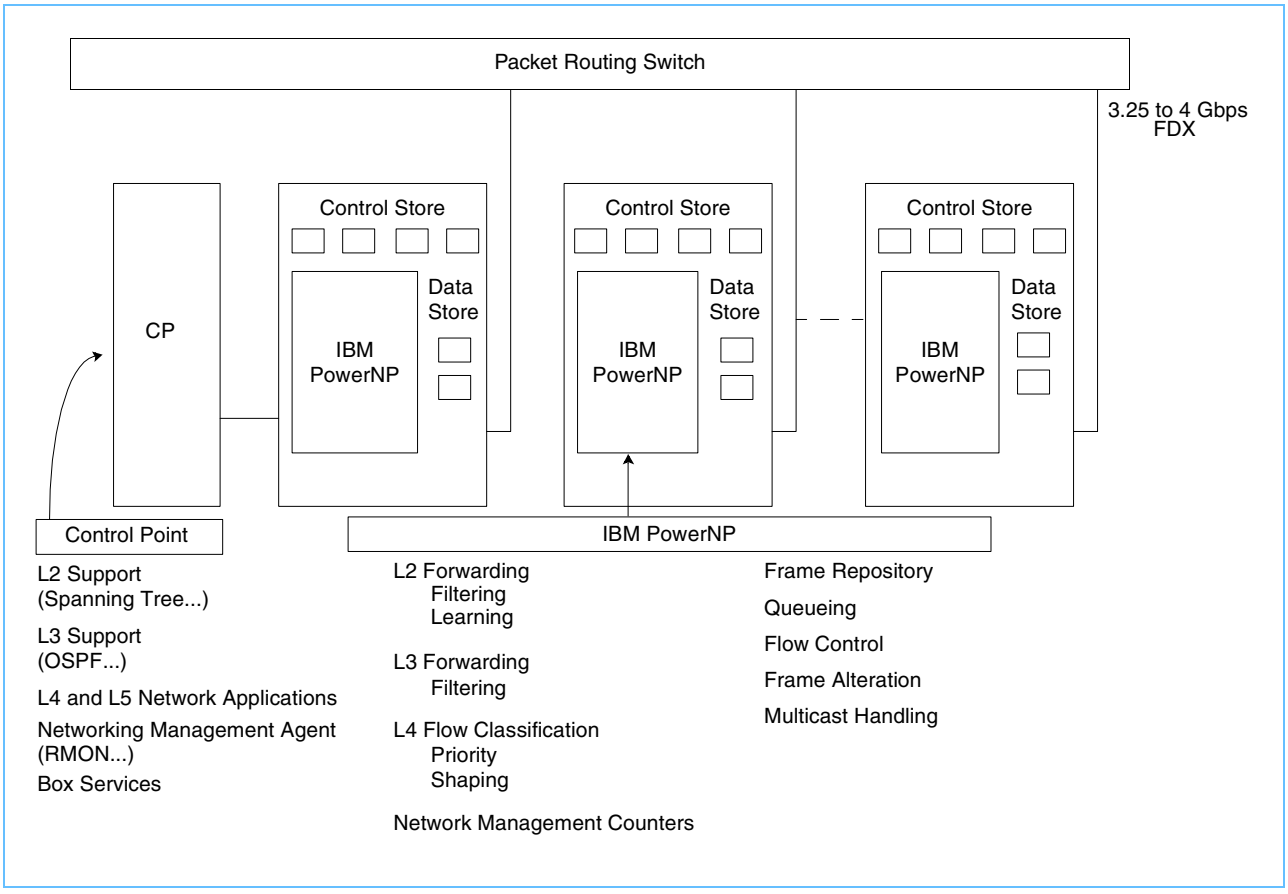
- Low-end systems with a single device that uses its own Switch Interface (SWI) to wrap traffic from the ingress to the egress side
- Medium-end systems with two devices that are directly connected through their SWIs
- High-end systems with up to 64 NP4GS3s that are connected through a single or redundant switch; a single IBM Packet Routing Switch can address up to 16 NP4GS3s.

  High-end systems can address up to 256 Gigabit Ethernet or 1024 Fast Ethernet or POS (OC-3) ports.

Systems developed with the NP4GS3 use a distributed software model, which relies on a control point to execute software instructions. In a high-end system, the control point may be an external microprocessor connected through an Ethernet link or the PCI interface. The NP4GS3's Embedded PowerPC processor can perform control point functions in a smaller system.

In this model, functions are divided between the control point and the network processor, as illustrated in *Figure 1-1*. The control point supports Layer 2 and Layer 3 routing protocols, Layer 4 and Layer 5 network applications, box maintenance, Management Information Base (MIB) collection (that is, the control point functions as an SNMP agent), and other systems management functions. Other functions, such as forwarding, filtering, and classification of the tables generated by the routing protocols, are performed by the dyadic protocol processor units (DPPUs) in each network processor in the system. The Core Language Processors (CLPs) in each DPPU execute the EPC's core software instruction set, which includes conditional execution, conditional branching, signed and unsigned operations, counts of leading zeros, and more.

Figure 1-1. Function Placement in an NP4GS3-Based System

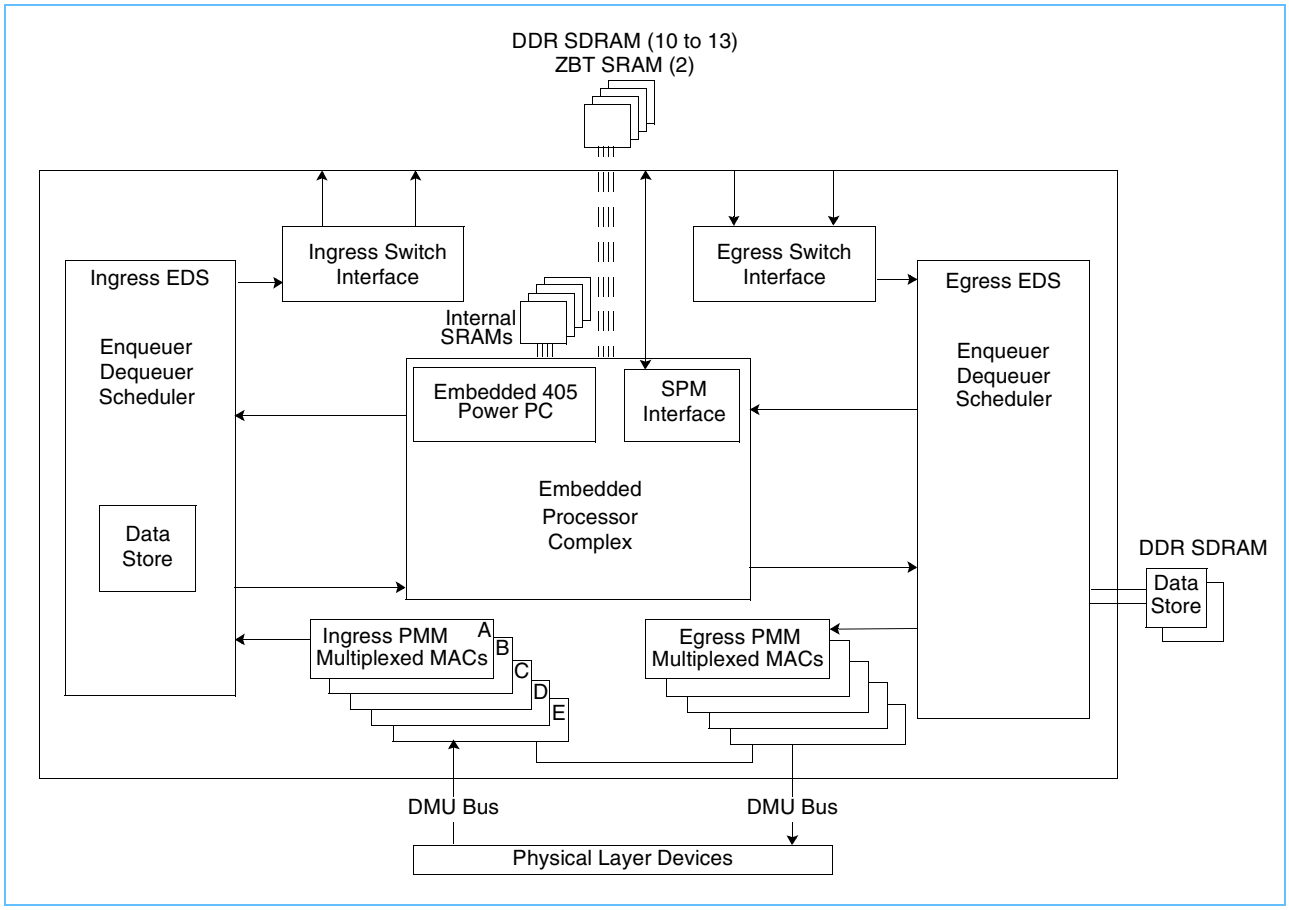


1.5 Structure

The IBM PowerNP NP4GS3 network processor has eight major functional blocks, as illustrated in *Figure 1-2*:

EPC	Provides all processing functions for the device.
Embedded PowerPC	Can act as a control point for the device; the Control Store interface provides up to 128 MB of program space for the PowerPC.
Ingress Enqueuer / Dequeuer / Scheduler (Ingress EDS)	Provides logic for frames traveling from the physical layer devices to the switch fabric.
Egress Enqueuer / Dequeuer / Scheduler (Egress EDS)	Provides logic for frames traveling from the switch fabric to the physical layer devices.
Ingress Switch Interface (Ingress SWI)	Transfers frames from the Ingress EDS to a switch fabric or another NP4GS3.
Egress Switch Interface (Egress SWI)	Transfers frames from a switch fabric or another NP4GS3 to the Egress EDS.
Ingress Physical MAC Multiplexer (Ingress PMM)	Receives frames from physical layer devices.
Egress Physical MAC Multiplexer (Egress PMM)	Transmits frames to physical layer devices.

Figure 1-2. NP4GS3 Major Functional Blocks



1.5.1 EPC Structure

The EPC contains eight dyadic protocol processor units (DPPUs). Each DPPU contains two Core Language Processors (CLPs) that share nine coprocessors, one coprocessor command bus, and a memory pool. The eight DPPUs share 32 threads, four of which are enhanced, and three hardware accelerators.

Together, the eight DPPUs are capable of operating on up to 32 frames in parallel. They share 16 K words (32 K words in NP4GS3B (R2.0)) of internal picocode instruction store, providing 2128 million instructions per second (MIPS) of processing power. In addition, the EPC contains a Hardware Classifier to parse frames on the fly, preparing them for processing by the picocode.

1.5.1.1 Coprocessors

Each DPPU contains two picocode processors, the CLPs, that execute the EPC's core instruction set and control thread swapping and instruction fetching. The two CLPs share eight dedicated coprocessors that can run in parallel with the CLPs:

Checksum	Calculates and verifies frame header checksums.
CAB Interface	Controls thread access to the Control Access Bus (CAB) through the CAB Arbiter; the CAB Control, CAB Arbiter, and CAB Interface enable debug access to NP4GS3 data structures.
Counter	Updates counters for the picocode engines.
Data Store	• Interfaces frame buffer memory (ingress and egress directions), providing a 320-byte working area. • Provides access to the Ingress and Egress Data Stores.
Enqueue	Manages control blocks containing key frame parameters; works with the Completion Unit hardware accelerator to enqueue frames to the switch and target port output queues.
Policy	Determines if the incoming data stream complies with configured profiles.
String Copy	Accelerates data movement between coprocessors within the shared memory pool.
Tree Search Engine	Performs pattern analysis through tree searches (based on algorithms provided by the picocode) and read and write accesses, all protected by memory range checking; accesses Control Store memory independently.
Semaphore Manager	Assists in controlling access to shared resources, such as tables and control structures, through the use of semaphores; grants semaphores either in dispatch order (ordered semaphores) or in request order (unordered semaphores).

1.5.1.2 Enhanced Threads

Each CLP can run two threads, making four threads per DPPU, or 32 total. Twenty-eight of the threads are General Data Handlers (GDHs), used for forwarding frames, and four of the 32 threads are enhanced:

Guided Frame Handler (GFH)	Handles Guided Frames, the in-band control mechanism between the EPC and all devices in the system, including the control point.
General Table Handler (GTH)	Builds table data in Control Memory
General PowerPC Handler Request (GPH-Req)	Processes frames bound to the Embedded PowerPC.
General PowerPC Handler Response (GPH-Resp)	Processes responses from the Embedded PowerPC.

1.5.1.3 Hardware Accelerators

The DPPUs share three hardware accelerators:

Completion Unit	Assures frame order as data exits the threads.
Dispatch Unit	Fetches data and parses the work out among the DPPUs.
Control Store Arbiter	Enables the processors to share access to the Control Store.

1.5.2 NP4GS3 Memory

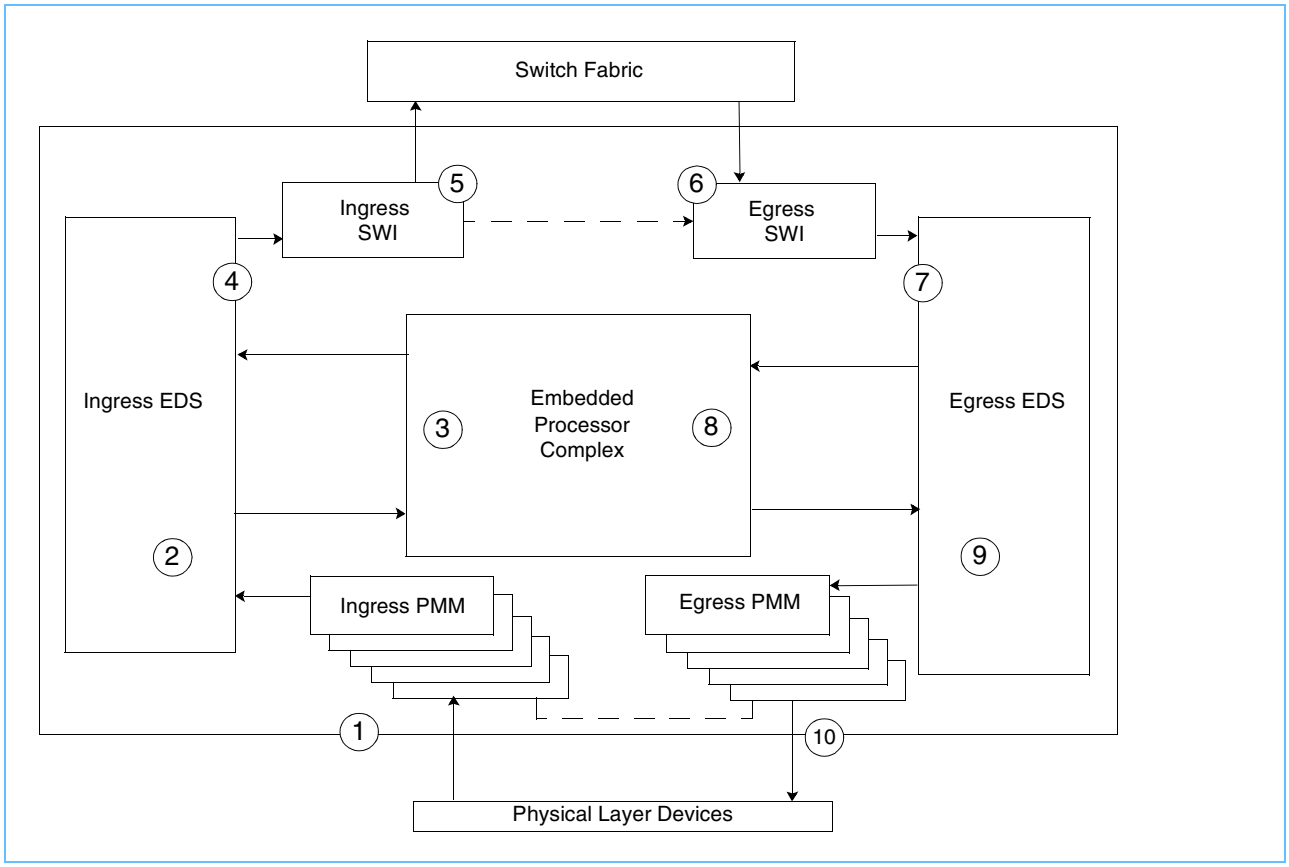
Storage for the NP4GS3 is provided by both internal and external memories (see *Figure 1-2* on page 30). The Control Store contains all tables, counters, and any other data needed by the picocode. The Data Stores contain the frame data to be forwarded and can be used by the picocode (via the Data Store coprocessor) to create guided traffic.

The NP4GS3 has the following stores:

- A common instruction memory that holds 16 K instruction words (32 K in NP4GS3B (R2.0)) for normal processing and control functions
- 128 KB internal SRAM for input frame buffering
- 113 KB internal SRAM Control Store
- High capacity external DDR SDRAM for egress frame buffering and large forwarding tables; the amount of memory can vary depending on the configuration.
- External ZBT SRAM for fast table access
  - Up to 512 KB × 36 in the Z0 interface
  - Up to 123 KB × 18 in the Z1 interface (for use by the Scheduler)

1.6 Data Flow

Figure 1-3. Data Flow Overview



1.6.1 Basic Data Flow

Too many data flow routes and possibilities exist to fully document in this overview. However, data generally moves through the NP4GS3 in the following manner (see *Figure 1-3*):

1. The Ingress PMM receives a frame from a physical layer device and forwards it to the Ingress EDS.
2. The Ingress EDS identifies the frame and enqueues it to the EPC.
3. The EPC processes the frame data (see *Section 1.6.2*).

   The EPC may discard the frame or modify the frame data directly and then return the updated data to the Ingress EDS's Data Store.
4. The frame is enqueued to the Ingress EDS, and the Ingress EDS Scheduler selects the frame for transmission and moves the data to the SWI.
5. The SWI forwards the frame to a switch fabric, to another NP4GS3, or to the Egress SWI of this device.
6. The Egress SWI receives a frame from a switch fabric, another NP4GS3, or from the Ingress SWI.
7. The SWI forwards the frame to the Egress EDS, which reassembles the frame and enqueues it to the EPC once it is fully reassembled.

8. The EPC processes it (see *Section 1.6.2*).

   The EPC may discard the frame or modify the frame directly and then return the data to the Egress EDS's Data Store.

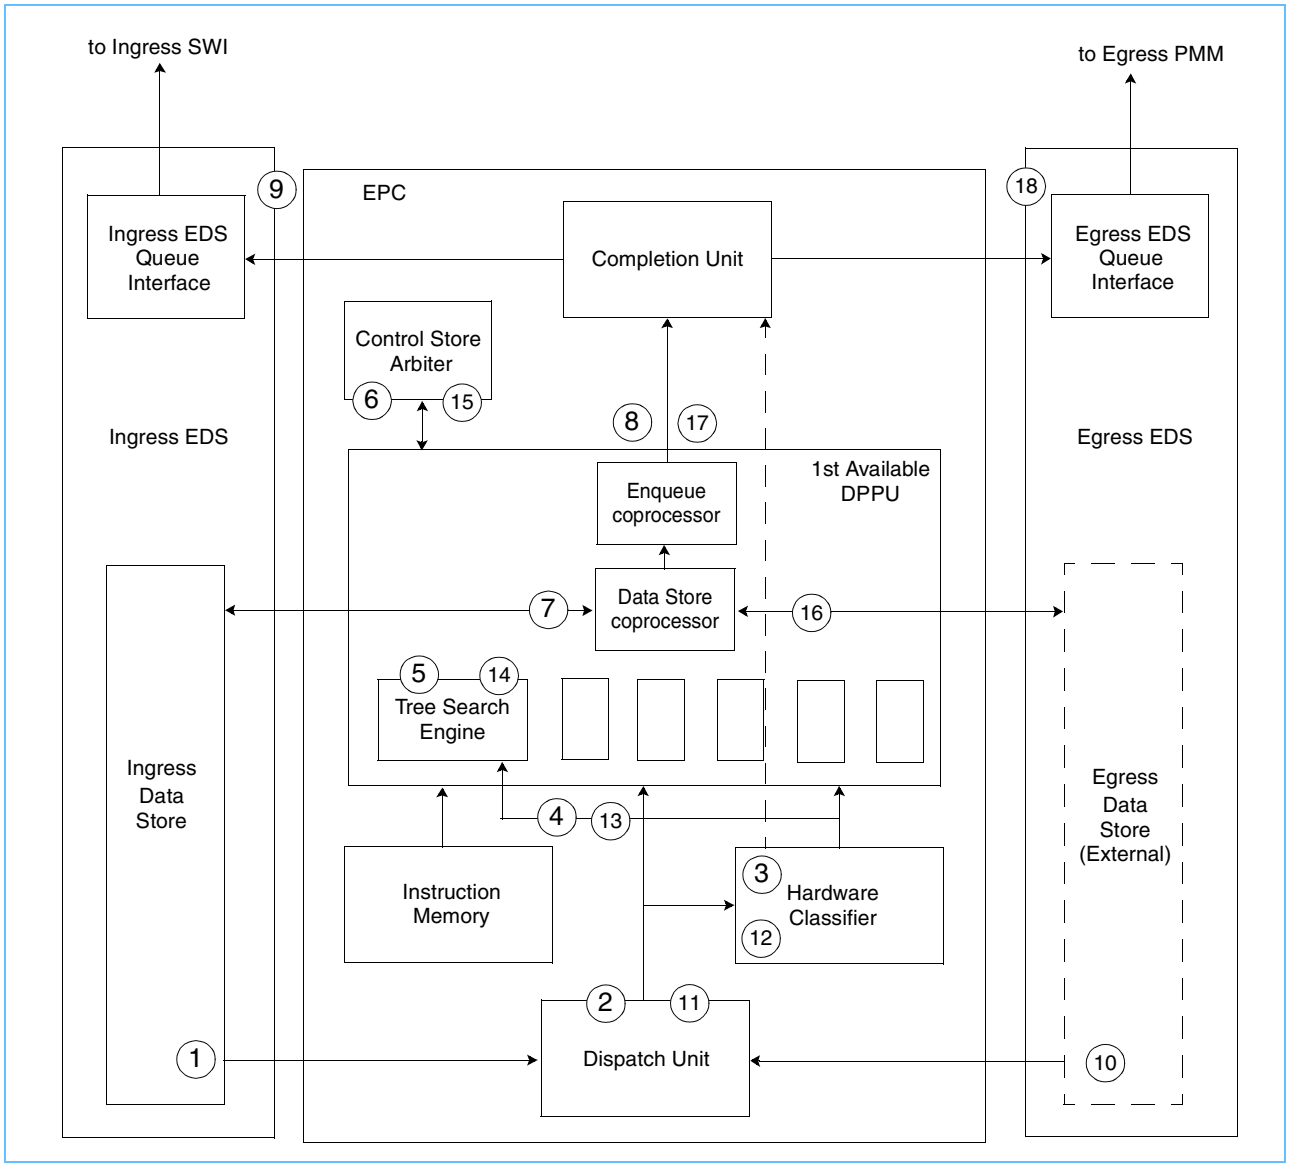
9. The frame is enqueued to the Egress EDS, and the Egress EDS Scheduler, if enabled, selects the frame for transmission and moves the data to the Egress PMM.

   If the Scheduler is not enabled, the EPC may forward the frame to a target port queue, to a wrap port, or to the GFH or GPH.

10. The Egress PMM sends the frame to a physical layer device.

1.6.2 Data Flow in the EPC

Figure 1-4. Basic Data Flow in the EPC



The EPC is the functional center of the device, and it plays a pivotal role in data flow. This section presents a basic overview of data flow in the EPC.

Ingress Side

1. The Ingress EDS enqueues a data frame to the EPC.
2. The Dispatch Unit fetches a portion of a frame and sends it to the next available thread.
3. Simultaneously, the Hardware Classifier (HC) determines the starting Common Instruction Address (CIA), parses different frame formats (for example: bridged, IP, and IPX), and forwards the results on to the thread.
4. The picocode examines the information from the HC and may examine the data further; it assembles search keys and launches the Tree Search Engine (TSE).
5. The TSE performs table searches, using search algorithms based on the format of the downloaded tables.
6. The Control Store Arbiter allocates Control Store memory bandwidth among the protocol processors.
7. Frame data moves into the Data Store coprocessor's memory buffer.
   - Forwarding and frame alteration information is identified by the results of the search.
   - The Ingress EDS can insert or overlay VLAN tags on the frame (hardware-assisted frame alteration) or the picocode can allocate or remove buffers to allow alteration of the frame (flexible frame alteration).
8. The Enqueue coprocessor builds the necessary information to enqueue the frame to the SWI and provides it to the Completion Unit (CU), which guarantees the frame order as the data moves from the 32 threads of the DPPU to the Ingress EDS queues.
9. The frame is enqueued to the Ingress EDS.
   - The Ingress EDS forwards the frame to the Ingress Scheduler.
   - The Scheduler selects the frame for transmission to the Ingress SWI.
     Note: The entire frame is not sent at once. The Scheduler sends it a cell at a time.
   - With the help of the Ingress EDS, The Ingress Switch Data Mover (I-SDM) (see *Section 4* beginning on page 133) segments the frames from the switch interface queues into 64-byte cells and inserts Cell Header and Frame Header bytes as they are transmitted to the SWI.

Egress Side

10. The Egress EDS enqueues a data frame to the EPC.
11. The Dispatch Unit fetches a portion of a frame and sends it to the next available thread.
12. Simultaneously, the HC determines the starting CIA, parses different frame formats (for example: bridged, IP, and IPX), and forwards the results to the thread.
13. The picocode examines the information from the HC and may examine the data further; it assembles search keys and launches the TSE.
14. The TSE performs table searches, using search algorithms based on the format of the downloaded tables.
15. The Control Store Arbiter allocates Control Store memory bandwidth among the protocol processors.
16. Frame data moves into the Data Store coprocessor's memory buffer.
    - Forwarding and frame alteration information is identified by the results of the search.
    - The NP4GS3 provides two frame alteration techniques: hardware-assisted frame alteration and flexible frame alteration:

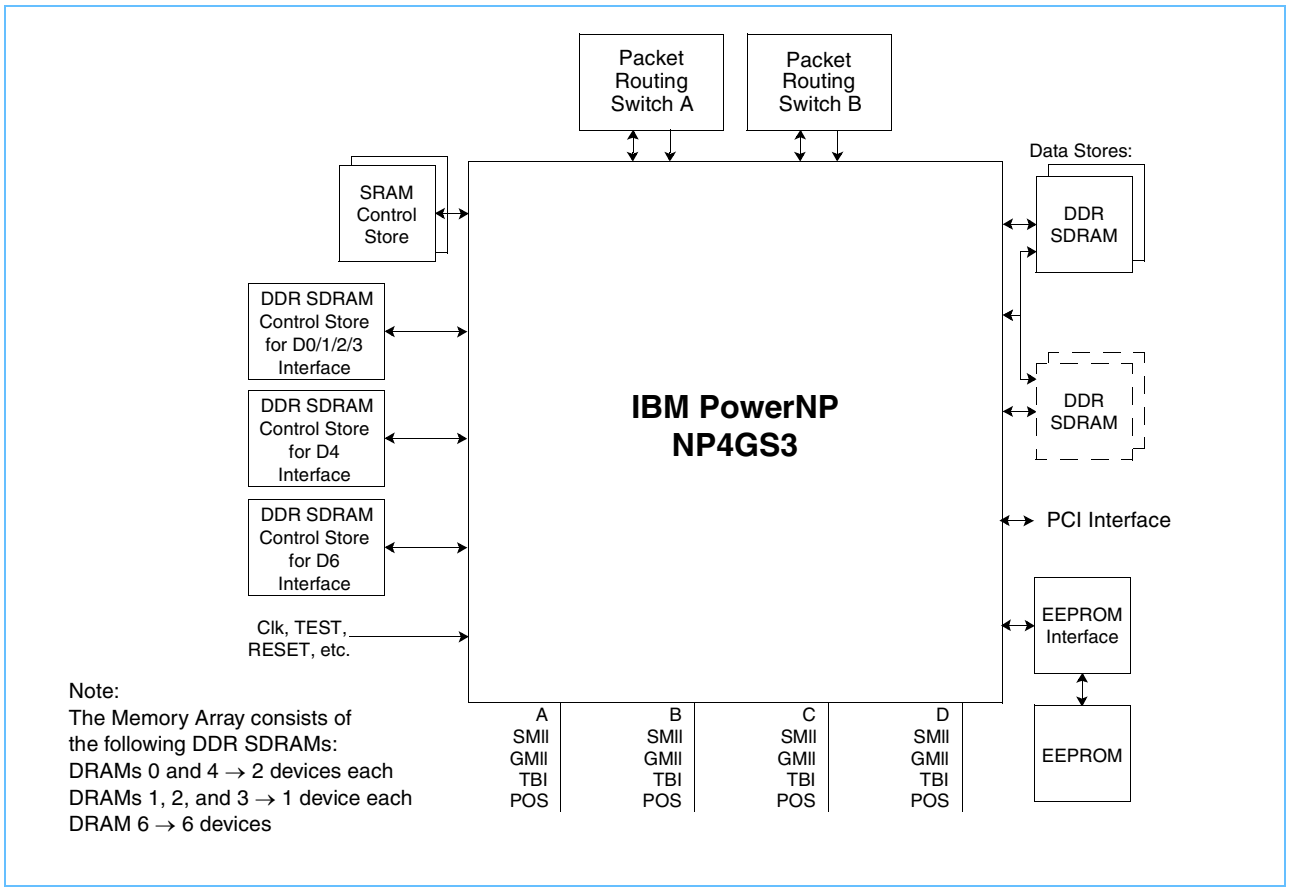
In hardware-assisted frame alteration, commands are passed to the Egress EDS hardware during enqueueing. These commands can, for example, update the TTL field in an IP header, generate frame CRC, or overlay an existing Layer 2 wrapper with a new one.

In flexible frame alteration, the picocode allocates additional buffers and the Data Store coprocessor places data into these buffers. The additional buffers allow prepending of data to a received frame and bypassing part of the received data when transmitting. This is useful for frame fragmentation when a when an IP header and MAC header must be prepended to received data in order to form a frame fragment of the correct size.

17. The Enqueue coprocessor builds the necessary information to enqueue the frame to the Egress EDS and provides it to the CU, which guarantees the frame order as the data moves from the 32 threads of the DPPU to the Egress EDS queues.
18. The frame is enqueued to the Egress EDS.
    - The frame is enqueued to the Egress EDS, which forwards it to the Egress Scheduler (if enabled).
    - The Scheduler selects the frame for transmission to a target port queue.
    - If the Scheduler is not enabled, the EDS will forward the frame directly to a target queue.
    - The Egress EDS selects frames for transmission from the target port queue and moves their data to the Egress PMM.

2. Physical Description

Figure 2-1. Device Interfaces



2.1 Pin Information

This section describes the many interfaces and associated pins of the NP4GS3 Network Processor. For a summary of all the device's interfaces and how many pins each contains, see *Table 2-1: Signal Pin Functions* on page 38.

For information on signal pin locations, see *Table 2-33: Complete Signal Pin Listing by Signal Name* on page 86 and *Table 2-34: Complete Signal Pin Listing by Grid Position* on page 96.

The following table groups the interfaces and pins by function, briefly describes them, and points to the location of specific information in the chapter.

Bits (1:0) Definition 00 No grants 01 Priority 0 and 1 granted 10 Priority 2 granted 11 Priority 0, 1 and 2 granted Bit 0 of this bus serves as the master grant for the high priority channel, and Bit 1 for the low priority channel. This signal runs at frequency Switch Clock * 2.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Send_Grant_A (Switch Clk * 2)	Send Grant A indicates whether the “A” connection of the NP4GS3 is able to receive cells from the switch fabric. 0 Unable (the Packet Routing Switch should send only idle cells) 1 Able The NP4GS3 changes the state of this signal.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Send_Grant_B (Switch Clk * 2)	Send Grant B indicates whether the “B” connection of the NP4GS3 is able to receive cells from the switch fabric. 0 Unable (the Packet Routing Switch should send only idle cells) 1 Able The NP4GS3 changes the state of this signal.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V

2.1.2 Flow Control Interface Pins

Table 2-3. Flow Control Pins

Signal	Description	Type
I_FreeQ_Th	Ingress Free Queue Threshold 0 Threshold not exceeded 1 Threshold exceeded	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
RES_Sync	Remote Egress Status synchronization (sync) is driven by the network processor that is configured to provide this signal. It is received by all other network processors. 1 Shared data bus sync pulse. Indicates start of time division multiplex cycle.	Input/Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
RES_Data	Remote Egress Status data is driven by a single network processor during its designated time slot. 0 Not exceeded 1 Network processor's exponentially weighted moving average (EWMA) of the egress offered rate exceeds the configured threshold.	Input/Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V

2.1.3 ZBT Interface Pins

These pins interface with Z0 and Z1 ZBT SRAM for lookups as described in *Table 2-4* and *Table 2-5*.

Table 2-4. Z0 ZBT SRAM Interface Pins

Signal	Description	Type
LU_Clk	Look-Up clock. 7.5 ns period (133 MHz).	Output CMOS 2.5 V
LU_Addr(18:0)	Look-Up Address signals are sampled by the rising edge of LU_Clk.	Output CMOS 2.5 V
LU_Data(35:0)	Look-Up Data. When used as SRAM inputs, the rising edge of LU_Clk samples these signals.	Input/Output CMOS 2.5 V
LU_R_$\overline{Wrt}$	Look-Up Read/Write control signal is sampled by the rising edge of LU_Clk. 0 Write 1 Read	Output CMOS 2.5 V

Table 2-5. Z1 ZBT SRAM Interface Pins

Signal	Description	Type
SCH_Clk	SRAM Clock input. 7.5 ns period (133 MHz).	Output CMOS 2.5 V
SCH_Addr(18:0)	SRAM Address signals are sampled by the rising edge of LU_Clk.	Output CMOS 2.5 V
SCH_Data(17:0)	Data bus. When used as SRAM input, the rising edge of SCH_Clk samples these signals.	Input/Output CMOS 2.5 V
SCH_R_$\overline{Wrt}$	Read/Write control signal is sampled by the rising edge of SCH_Clk. 0 Write 1 Read	Output CMOS 2.5 V

Figure 2-2. ZBT SRAM Timing Diagram

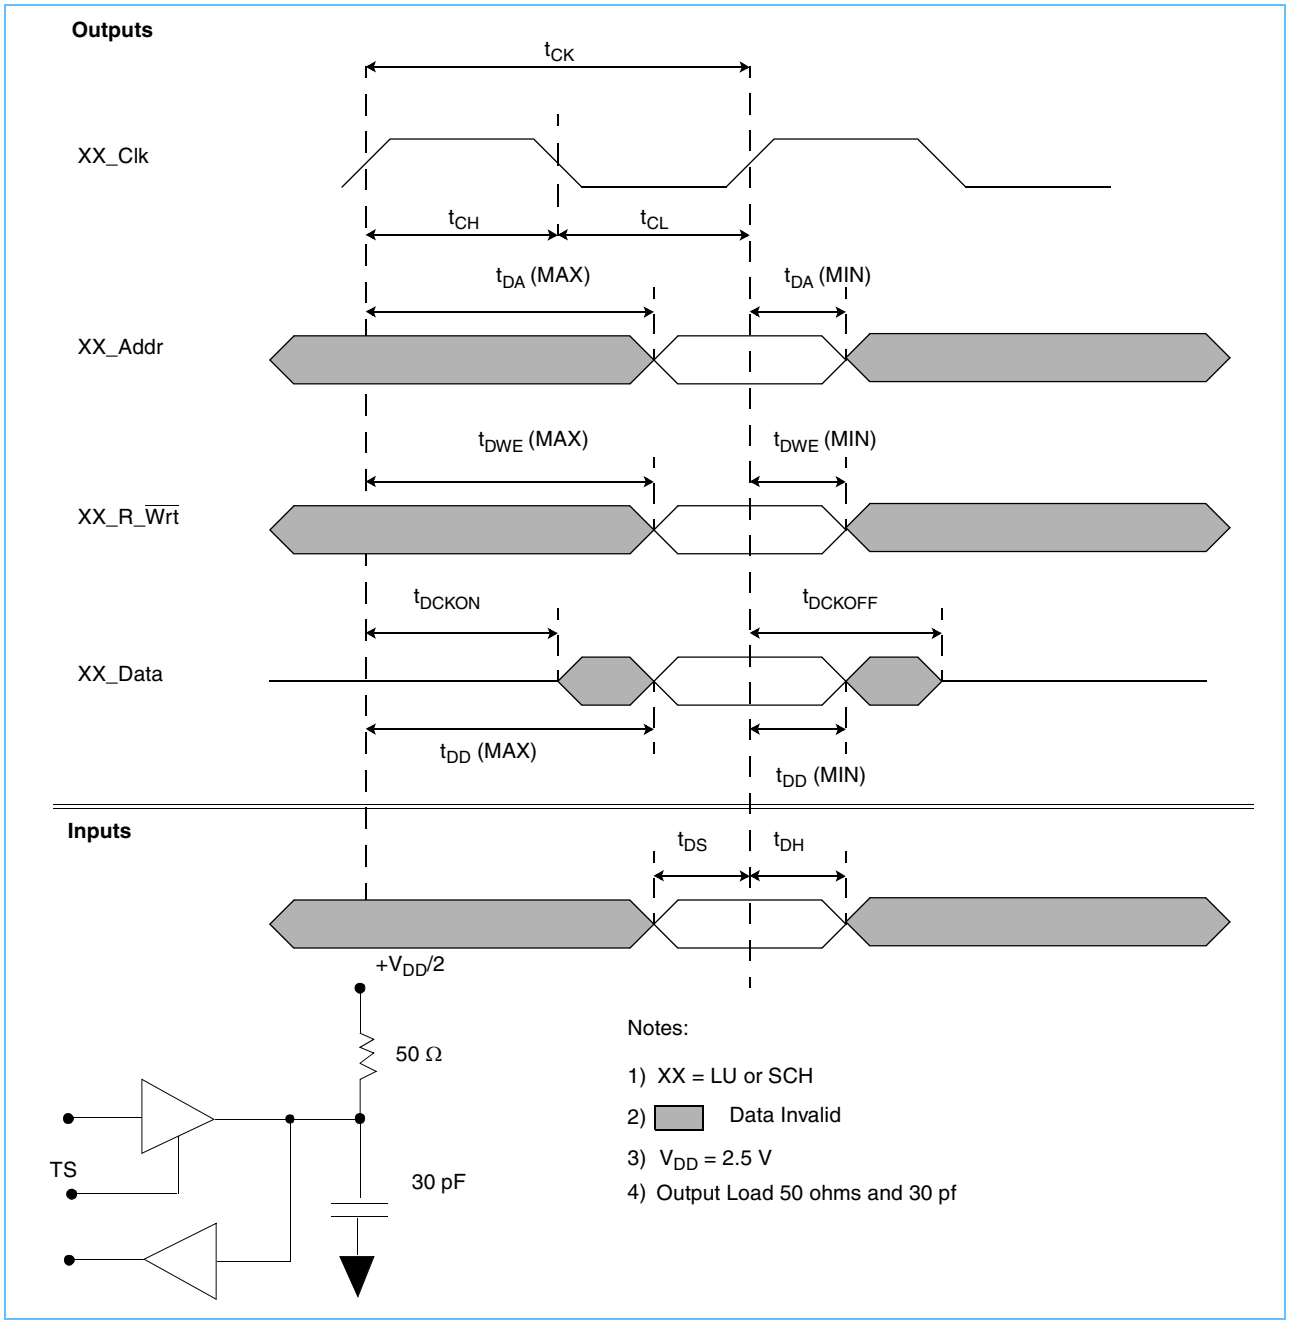

Table 2-6. ZBT SRAM Timing Diagram Legend (for Figure 2-2)

Symbol	Symbol Description	NP4GS3A (R1.1)		NP4GS3	
		Minimum (ns)	Maximum (ns)	Minimum (ns)	Maximum (ns)
t_{CK}	ZBT Cycle Time	7.5		7.5	
t_{CH}	Clock Pulse Width High	2.8	4.2	3.3	4.1
t_{CL}	Clock Pulse Width Low	3.3	4.7	3.4	4.2
t_{DA}	Address Output Delay	2.2	4.3	1.0	4.7
t_{DWE}	Read/Write Output Delay	2.9	5.3	1.1	2.6
t_{DD}	Data Output Delay	1.7	5.0	0.7	2.7
t_{DCKON}	Data Output Turn On	1.0	3.2	1.3	4.1
t_{DCKOFF}	Data Output Turn Off	0.5	2.3	0.8	3.0
t_{DS}	Input Data Setup Time	1.5		1.0	
t_{DH}	Input Data Hold Time	1.7		0	

Note: All delays are measured with 1 ns slew time measured from 10 - 90% of input voltage.

Note: Column for NP4GS3 is for all releases of the NP other than R1.1.

2.1.4 DDR DRAM Interface Pins

The pins described here interface with DDR DRAM to implement data store, control store, and the PowerPC store. The control, read, and write timing diagrams (*Figure 2-3*, *Figure 2-4*, and *Figure 2-5*) apply to all pin tables in this section.

Figure 2-3. DDR Control Timing Diagram

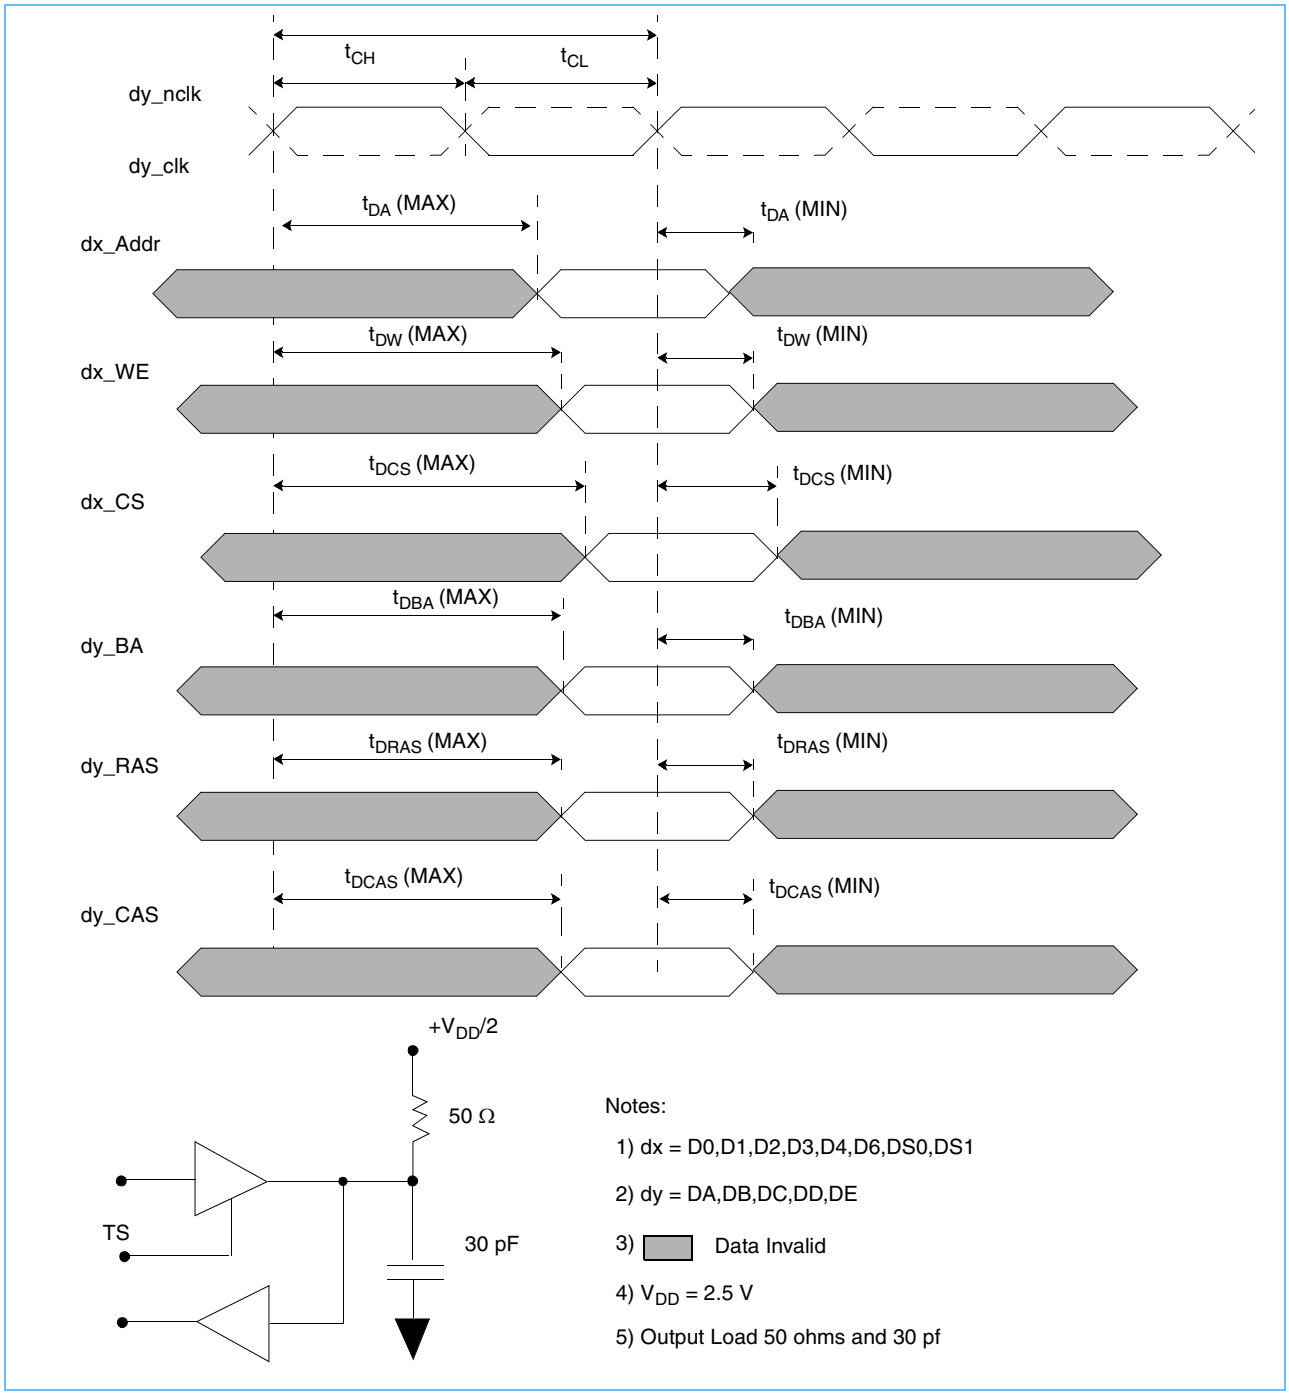

Figure 2-4. DDR Read Timing Diagram

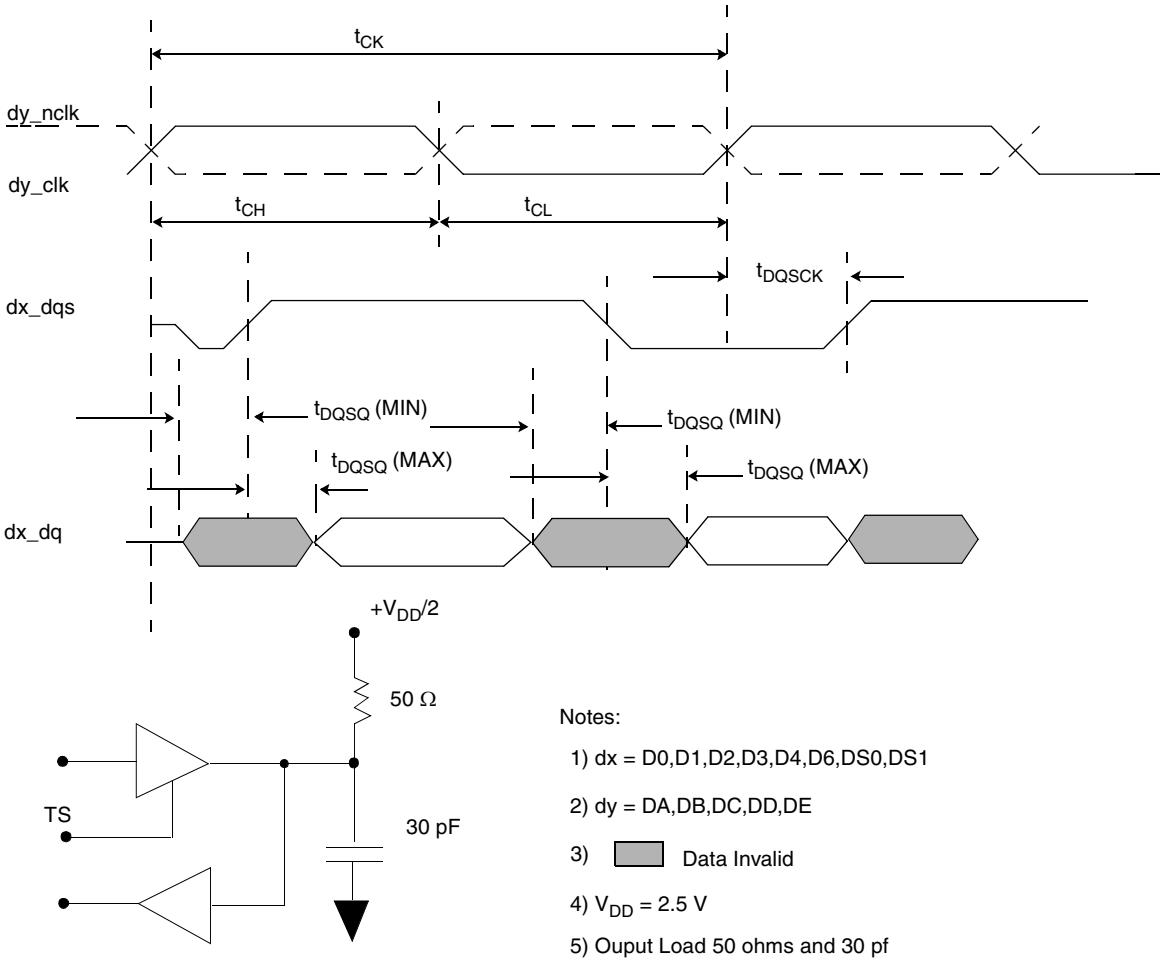

Figure 2-5. DDR Write Output Timing Diagram

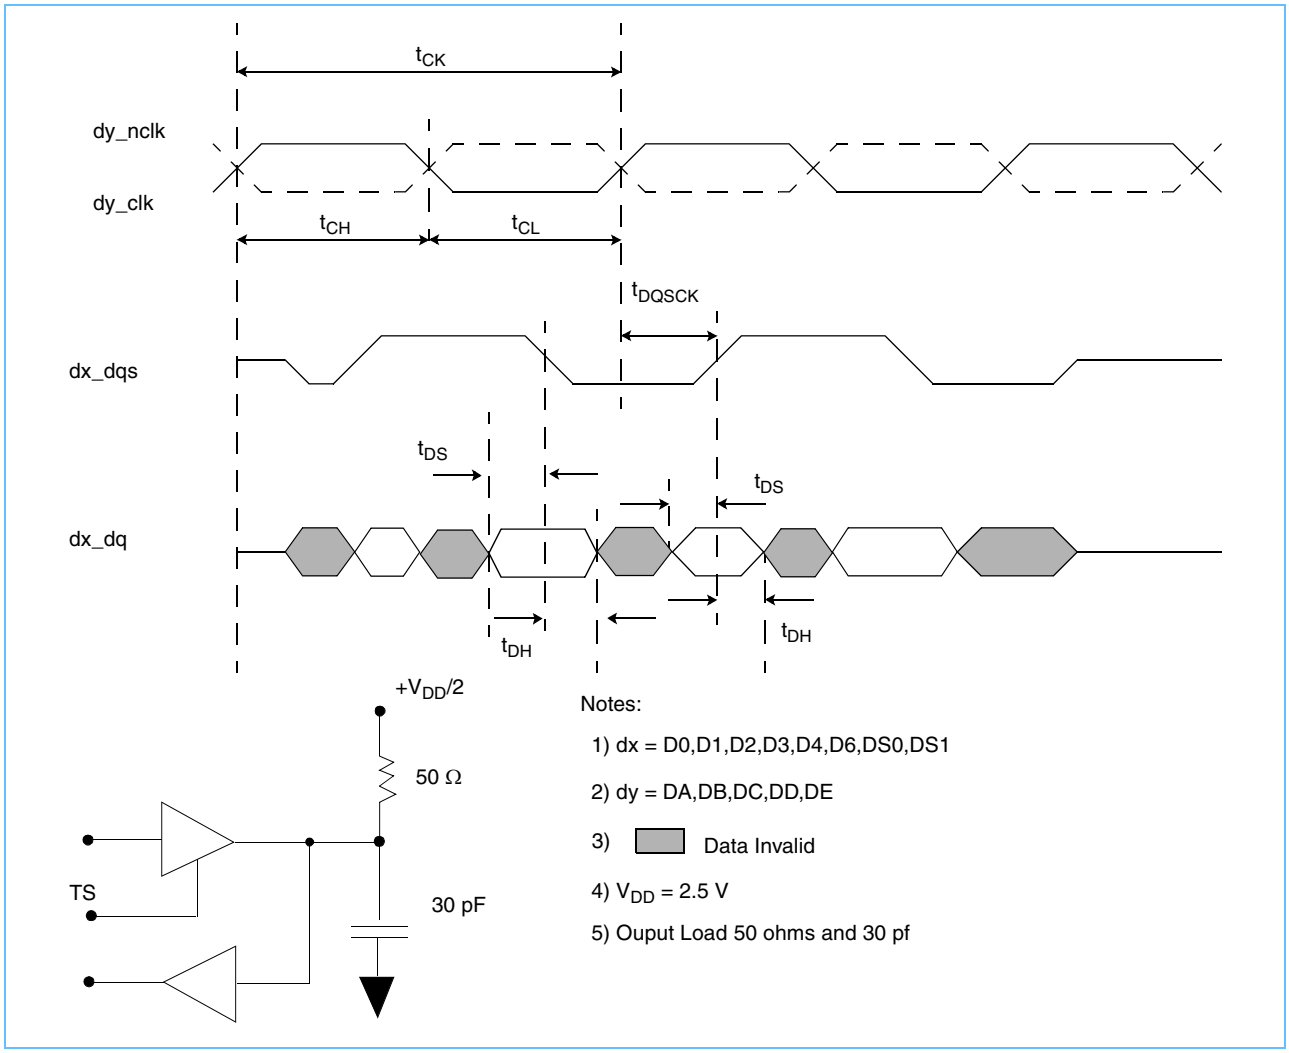

Table 2-7. DDR Timing Diagram Legend (for Figure 2-3, Figure 2-4, and Figure 2-5) Values are for D0, D1, D2, D3, D4, DS0 and DS1

Symbol	Symbol Description	Minimum (ns)	Maximum (ns)
t_{CK}	DDR Clock Cycle Time	7.5	
t_{DQSCK}	dy_clk to dx_dqs strobe Delay	0.2	1.7
t_{CH}	Clock Pulse Width High	0.45 * t_{CK}	0.55 * t_{CK}
t_{CL}	Clock Pulse Width Low	0.45 * t_{CK}	0.55 * t_{CK}
t_{DQSQ}	DQ Data to DQS Skew	0.7	0.8
t_{DA}	Address Output Delay	1.7	4.8
t_{DW}	Write Enable Output Delay	2.0	5.2
t_{DCS}	Chip Select Output Delay	1.9	5.2
t_{BA}	Bank Address Output Delay	1.9	5.2
t_{DRAS}	RAS Output Delay	1.7	5.4
t_{DCAS}	CAS Output Delay	1.8	5.4
t_{DS}	Data to Strobe Setup Time	0.7	
t_{DH}	Data to Strobe Hold Time	0.9	

Note: All delays are measured with 1 ns slew time measured from 10-90% of input voltage.
All measurements made with Test Load of 50 ohms and 30 pf.

Table 2-8. DDR Timing Diagram Legend (for Figure 2-3, Figure 2-4, and Figure 2-5) Values are for D6.

Symbol	Symbol Description	Minimum (ns)	Maximum (ns)
t_{CK}	DDR Clock Cycle Time	7.5	
t_{DQSCK}	dy_clk to dx_dqs strobe Delay	0.3	2.1
t_{CH}	Clock Pulse Width High	0.45 * t_{CK}	0.55 * t_{CK}
t_{CL}	Clock Pulse Width Low	0.45 * t_{CK}	0.55 * t_{CK}
t_{DQSQ}	DQ Data to DQS Skew	0.4	0.8
t_{DA}	Address Output Delay	2.4	6.0
t_{DW}	Write Enable Output Delay	2.4	5.6
t_{DCS}	Chip Select Output Delay	2.5	5.9
t_{BA}	Bank Address Output Delay	2.3	5.7
t_{DRAS}	RAS Output Delay	2.4	5.7
t_{DCAS}	CAS Output Delay	2.5	5.7
t_{DS}	Data to Strobe Setup Time	0.8	
t_{DH}	Data to Strobe Hold Time	0.6	

Note: All delays are measured with 1 ns slew time measured from 10-90% of input voltage.
All measurements made with Test Load of 50 ohms and 30 pf.

2.1.4.1 D3, D2, D1, and D0 Interface Pins

These pins interface with the DDR SDRAM used to implement the D3, D2, D1, and D0 control stores.

Table 2-9. D3, D2, and D1 Interface Pins (Page 1 of 2)

Signal	Description	Type
Shared Signals		
DB_Clk	The positive pin of an output differential pair. 133 MHz. Common to the D3, D2, and D1 memory devices.	Output SSTL2 2.5 V
$\overline{\text{DB\_Clk}}$	The negative pin of an output differential pair. 133 MHz. Common to the D3, D2, and D1 memory devices.	Output SSTL2 2.5 V
DB_RAS	Common row address strobe (common to D3, D2, and D1).	Output SSTL2 2.5 V
DB_CAS	Common column address strobe (common to D3, D2, and D1).	Output SSTL2 2.5 V
DB_BA(1:0)	Common bank address (common to D3, D2, and D1).	Output SSTL2 2.5 V
D3 Signals		
D3_Addr(12:0)	D3 address	Output CMOS 2.5 V

Table 2-9. D3, D2, and D1 Interface Pins (Page 2 of 2)

Signal	Description	Type
D3_DQS(1:0)	D3 data strobes	Input/Output SSTL2 2.5 V
D3_Data(15:0)	D3 data bus	Input/Output SSTL2 2.5 V
D3_WE	D3 write enable	Output CMOS 2.5 V
D3_CS	D3 chip select	Output CMOS 2.5 V
D2 Signals		
D2_Addr(12:0)	D2 address	Output CMOS 2.5 V
D2_DQS(1:0)	D2 data strobes	Input/Output SSTL2 2.5 V
D2_Data(15:0)	D2 data bus	Input/Output SSTL2 2.5 V
D2_WE	D2 write enable	Output CMOS 2.5 V
D2_CS	D2 chip select	Output CMOS 2.5 V
D1 Signals		
D1_Addr(12:0)	D1 address	Output CMOS 2.5 V
D1_DQS(1:0)	D1 data strobes	Input/Output SSTL2 2.5 V
D1_Data(15:0)	D1 data bus	Input/Output SSTL2 2.5 V
D1_WE	D1 write enable	Output CMOS 2.5 V
D1_CS	D1 chip select	Output CMOS 2.5 V

Table 2-10. D0 Memory Pins

Signal	Description	Type
D0_0 and D0_1 Shared Signals		
DE_Clk	The positive pin of an output differential pair. 133 MHz. Common to the D0_0/1 memory devices.	Output SSTL2 2.5 V
DE_$\overline{Clk}$	The negative pin of an output differential pair. 133 MHz. Common to the D0_0/1 devices.	Output SSTL2 2.5 V
DE_RAS	Common row address strobe	Output CMOS 2.5 V
DE_CAS	Common column address strobe	Output CMOS 2.5 V
DE_BA(1:0)	Common bank address	Output CMOS 2.5 V
D0_Addr(12:0)	D0 address	Output CMOS 2.5 V
D0_DQS(3:0)	D0 data strobes	Input/Output SSTL2 2.5 V
D0_Data(31:0)	D0 data bus	Input/Output SSTL2 2.5 V
D0_WE	D0 write enable	Output CMOS 2.5 V
D0_CS	D0 chip select	Output CMOS 2.5 V

2.1.4.2 D4_0 and D4_1 Interface Pins

These pins interface with the DDR DRAM used to implement the D4 control store.

Table 2-11. D4_0 and D4_1 Interface Pins (Page 1 of 2)

Signal	Description	Type
DD_Clk	The positive pin of an output differential pair. 133 MHz. Common to the D4_0/1 memory devices.	Output SSTL2 2.5 V
DD_$\overline{Clk}$	The negative pin of an output differential pair. 133 MHz. Common to the D4_0/1 memory devices.	Output SSTL2 2.5 V
DD_RAS	Common row address strobe	Output CMOS 2.5 V

Table 2-11. D4_0 and D4_1 Interface Pins (Page 2 of 2)

Signal	Description	Type
DD_CAS	Common column address strobe	Output CMOS 2.5 V
DD_BA(1:0)	Common bank address	Output CMOS 2.5 V
D4_Addr(12:0)	D4 address	Output CMOS 2.5 V
D4_DQS(3:0)	D4 data strobes. When Strobe_cntl is set to '01' only D4_DQS(0) is in use. (NP4GS3B (R2.0) or later).	Input/Output SSTL2 2.5 V
D4_Data(31:0)	D4 data bus	Input/Output SSTL2 2.5 V
D4_WE	D4 write enable	Output CMOS 2.5 V
D4_CS	D4 chip select	Output CMOS 2.5 V

2.1.4.3 D6_*x* Interface Pins

These pins interface with the DDR SDRAM used to implement the PowerPC store.

Table 2-12. D6_5, D6_4, D6_3, D6_2, D6_1, and D6_0 Memory Pins (Page 1 of 2)

Signal	Description	Type
DA_Clk	The positive pin of an output differential pair. 133 MHz. Common to the D6 memory devices.	Output SSTL2 2.5 V
DA_$\overline{\text{Clk}}$	The negative pin of an output differential pair. 133 MHz. Common to the D6 memory devices.	Output SSTL2 2.5 V
DA_RAS	Common row address strobe (common to D6).	Output SSTL2 2.5 V
DA_CAS	Common column address strobe (common to D6).	Output SSTL2 2.5 V
DA_BA(1:0)	Common bank address (common to D6).	Output SSTL2 2.5 V
D6_WE	Common write enable (common to D6).	Output SSTL2 2.5 V
D6_Addr(12:0)	D6 address	Output SSTL2 2.5 V

Table 2-12. D6_5, D6_4, D6_3, D6_2, D6_1, and D6_0 Memory Pins (Page 2 of 2)

Signal	Description	Type
D6_CS	D6 chip select	Output SSTL2 2.5 V
D6_DQS(3:0)	D6 data strobes. When D6 is configured for 16-bit interface mode (D6_DRAM_Size = '0xx'), then only bits 0 and 2 are used (NP4GS3B (R2.0)).	Input/Output SSTL2 2.5 V
D6_Data(15:0)	D6 data bus	Input/Output SSTL2 2.5 V
D6_ByteEn(1:0)	D6 byte enables byte masking write to D6.	Input/Output SSTL2 2.5 V
D6_Parity(1:0)	D6 parity signals, one per byte. Must go to separate chips to allow for byte write capability.	Input/Output SSTL2 2.5 V
D6_DQS_Par(1:0)	D6 data strobe for the parity signals	Input/Output SSTL2 2.5 V

2.1.4.4 DS1 and DS0 Interface Pins

These pins interface with the DDR DRAM used to implement the DS1 and DSO data stores.

Table 2-13. DS1 and DS0 Interface Pins

Signal	Description	Type
Shared Signals		
DC_Clk	The positive pin of an output differential pair. 133 MHz. Common to the DS1 and DS0 memory devices.	Output SSTL2 2.5 V
DC_$\overline{\text{Clk}}$	The negative pin of an output differential pair. 133 MHz. Common to the DS1 and DS0 memory devices.	Output SSTL2 2.5 V
DC_RAS	Common Row address strobe (common to DS1 and DS0).	Output SSTL2 2.5 V
DC_CAS	Common Column address strobe (common to DS1 and DS0).	Output SSTL2 2.5 V
DC_BA(1:0)	Common bank address (common to DS1 and DS0).	Output SSTL2 2.5 V
DS1 Signals		
DS1_Addr(12:0)	DS1 address	Output CMOS 2.5 V
DS1_DQS(3:0)	DS1 data strobes. When Strobe_cntl is set to '01' only DS1_DQS(0) is in use. (NP4GS3B (R2.0) or later).	Input/Output SSTL2 2.5 V

Table 2-13. DS1 and DS0 Interface Pins

Signal	Description	Type
DS1_Data(31:0)	DS1 data bus	Input/Output SSTL2 2.5 V
DS1_WE	DS1 write enable	Output CMOS 2.5 V
DS1_CS	DS1 chip select	Output CMOS 2.5 V
DS0 Signals		
DS0_Addr(12:0)	DS0 address	Output CMOS 2.5 V
DS0_DQS(3:0)	DS0 data strobes. When Strobe_cntl is set to '01' only DS0_DQS(0) is in use. (NP4GS3B (R2.0) or later).	Input/Output SSTL2 2.5 V
DS0_Data(31:0)	DS0 data bus	Input/Output SSTL2 2.5 V
DS0_WE	DS0 write enable	Output CMOS 2.5 V
DS0_CS	DS0 chip select	Output CMOS 2.5 V

2.1.5 PMM Interface Pins

These pins allow the Physical MAC Multiplexer (PMM) to interface with the physical layer devices. The NP4GS3 has different sets of pins for the Ten-Bit (TBI), Gigabit Media-Independent (GMII), Serial Media-Independent (SMII), and Packet over SONET (POS) interfaces.

Table 2-14. PMM Interface Pins

Signal	Description	Type
DMU_A(30:0)	Define the first of the four PMM interfaces and can be configured for TBI, SMII, GMII, or POS. See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for pin directions and definitions.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
DMU_B(30:0)	Define the second of the four PMM interfaces and can be configured for TBI, SMII, GMII, or POS. See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for pin directions and definitions.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
DMU_C(30:0)	Define the third of the four PMM interfaces and can be configured for TBI, SMII, GMII, or POS. See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for pin directions and definitions.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
DMU_D(30:0)	Define the fourth of the four PMM interfaces and can be configured for TBI, SMII, GMII, Debug, or POS. See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for pin directions and definitions.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_LByte(1:0)	Receive last byte position (valid for 32-bit POS only) provides the position of the last byte within the final word of the packet transfer. This signal is valid only when Rx_EOF is high.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V

Table 2-15. PMM Interface Pin Multiplexing

Pin(s)	Pin Mode		Interface Type				
	DMU_A, DMU_B, DMU_C	DMU_D	GMII	TBI	SMII	Debug (DMU_D only)	8-Bit POS
30	O	O					RxAddr(1) O
29	O	O					RxAddr(0) O
28	O	O					TxAddr(1) O
27	O	O					TxAddr(0) O
26	O	O					TxSOF O
25	O	O	Tx_Valid_Byte O				TxEOF O

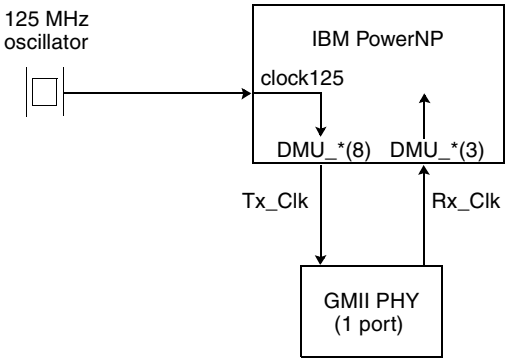
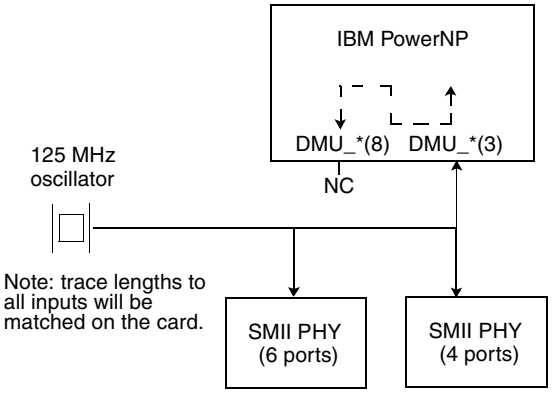
(16:9)	I	I/O	Rx_Data(7:0) I	Rx_Data(0:7) I	Rx_Data(9:2) I	Debug(15:8) I/O	RxData(7:0) I
8	O	O	Tx_Clk 8 ns	Tx_Clk 8 ns	—	—	—
7	O	I/O	Tx_En O	Tx_Data(8) O	Tx_Data(1) O	Debug(7) I/O	$\overline{\text{TxEn}}$ O
6	I/O	I/O	Tx_Er O	Tx_Data(9) O	Tx_Data(0) O	Debug(6) I/O	TxPFA I
5	I	I/O	Rx_Valid_Byte I	Rx_Data(8) I	Rx_Data(1) I	Debug(5) I/O	RxPFA I
4	I	I/O	Tx_Byte_Credit I	Rx_Data(9) I	Rx_Data(0) I	Debug(4) I/O	RxVal I
3	I	I/O	Rx_Clk I 8 ns	Rx_Clk1 I 16 ns	Clk I 8 ns	Debug(3) O	Clk I 10 ns
2	I/O	I/O	Rx_DV I	Rx_Clk0 I 16 ns	Sync O	Debug(2) I/O	RxEOF I
1	I/O	I/O	Rx_Er I	Sig_Det I	Sync2 O	Debug(1) I/O	RxErr I
0	I/O	I/O	$\overline{\text{CPDetect}}$ (0 = CPF) - Input	$\overline{\text{CPDetect}}$ (0 = CPF) - Input Activity - Output	$\overline{\text{CPDetect}}$ (0 = CPF) - Input	Debug(0) I/O	RxEnb O

Figure 2-6. NP4GS3 DMU Bus Clock Connections

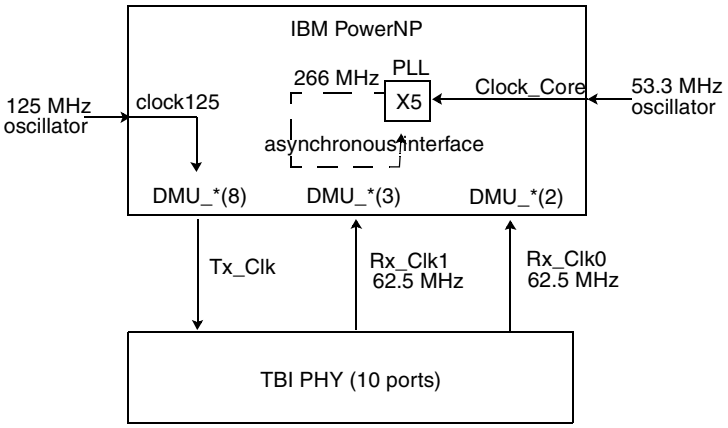
GMII Interface



SMII Interface

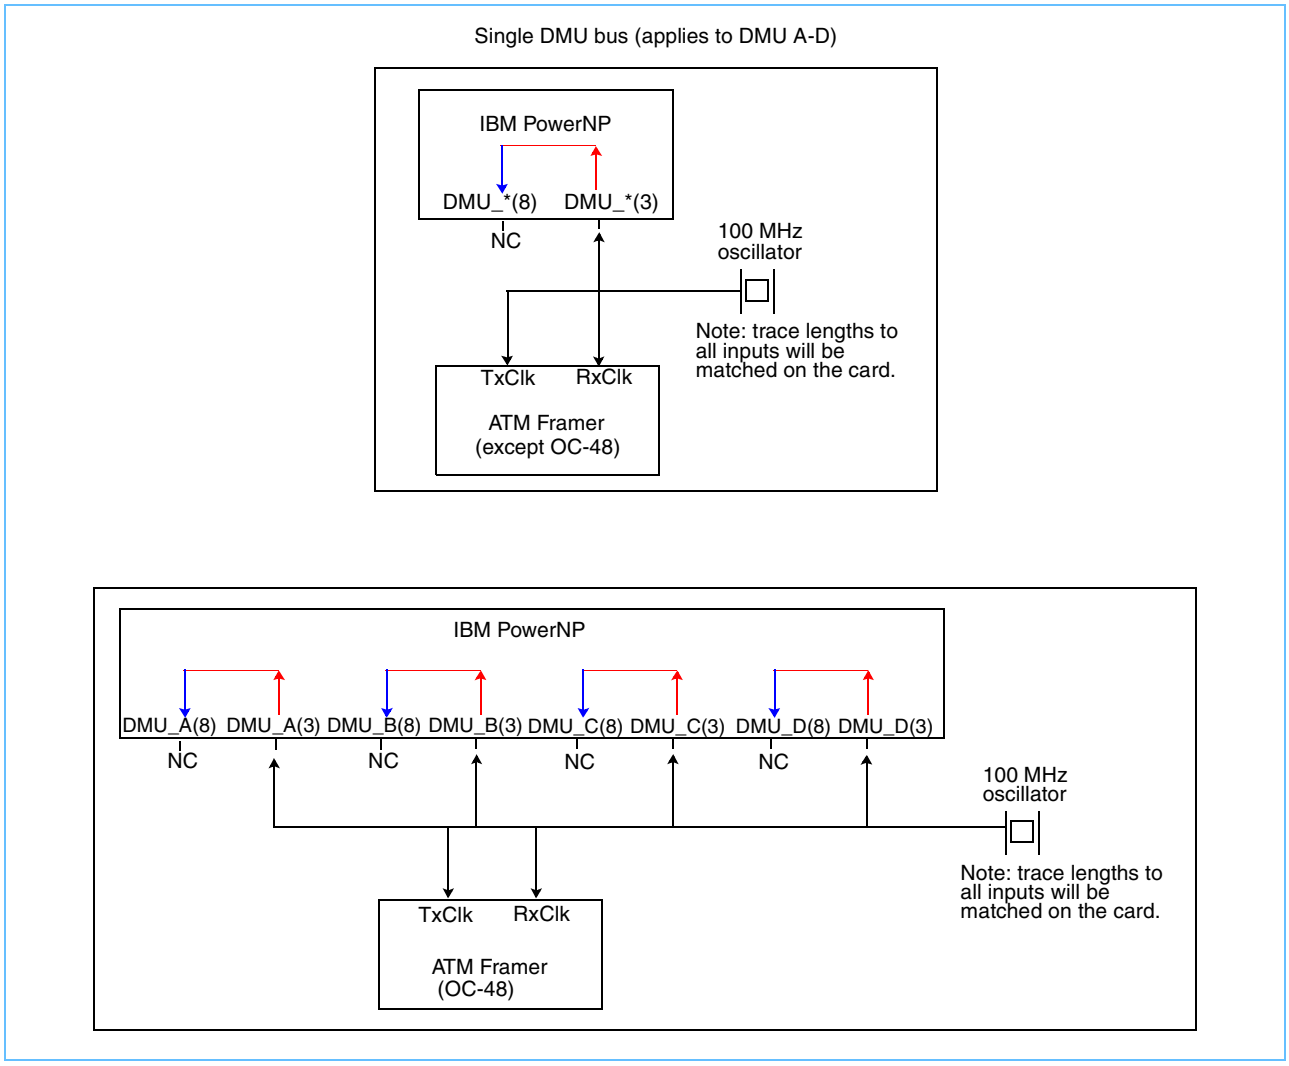


TBI Interface



Notes: Each figure above illustrates a single DMU bus and applies to any of the four DMU busses.
The “DMU_*” labels represent any of the four DMU busses (DMU_A, DMU_B, DMU_C, or DMU_D).

Figure 2-7. NP4GS3 DMU Bus Clock Connections (POS Overview)



2.1.5.1 TBI Bus Pins

Table 2-16. Parallel Data Bit to 8B/10B Position Mapping (TBI Interface)

Parallel Data Bit	0	1	2	3	4	5	6	7	8	9
8B/10B Bit Position	a	b	c	d	e	f	g	h	i	j

Table 2-17. PMM Interface Pins: TBI Mode

Signal	Description	Type
Tx_Data(9:0)	Transmit data. Data bus to the PHY, synchronous to Tx_Clk.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Data(9:0)	Receive data. Data bus from the PHY, synchronous to Rx_Clk1 and Rx_Clk0. (Data switches at double the frequency of Rx_Clk1 or Rx_Clk0.)	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Clk1	Receive Clock, 62.5 MHz. Rx_Data is valid on the rising edge of this clock.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Clk0	Receive Clock, 62.5 MHz. This signal is 180 degrees out of phase with Rx_Clk1. Rx_Data is valid on the rising edge of this clock.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Sig_Det	Signal Detect. Signal asserted by the PHY to indicate that the physical media are valid.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{CPDetect}}$	The Control Point card drives this signal active low to indicate its presence. When a non-Control Point card is plugged in, or this device pin is not connected, this signal should be pulled to a '1' on the card. During operation, this signal is driven by the network processor to indicate the status of the interface. 0 TBI interface is not in the data pass state (link down) 1 TBI interface is in the data pass state (occurs when auto-negotiation is complete, or when idles are detected (if AN is disabled)) pulse TBI interface is in a data pass state and is either receiving or transmitting. The line pulses once per frame transmitted or received at a maximum rate of 8Hz.	Input/Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Tx_Clk	125 MHz clock Transmit clock to the PHY. During operation, the network processor drives this signal to indicate that a transmit or receive is in progress for this interface.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V

Note: See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for pin directions (I/O) and definitions.

Figure 2-8. TBI Timing Diagram

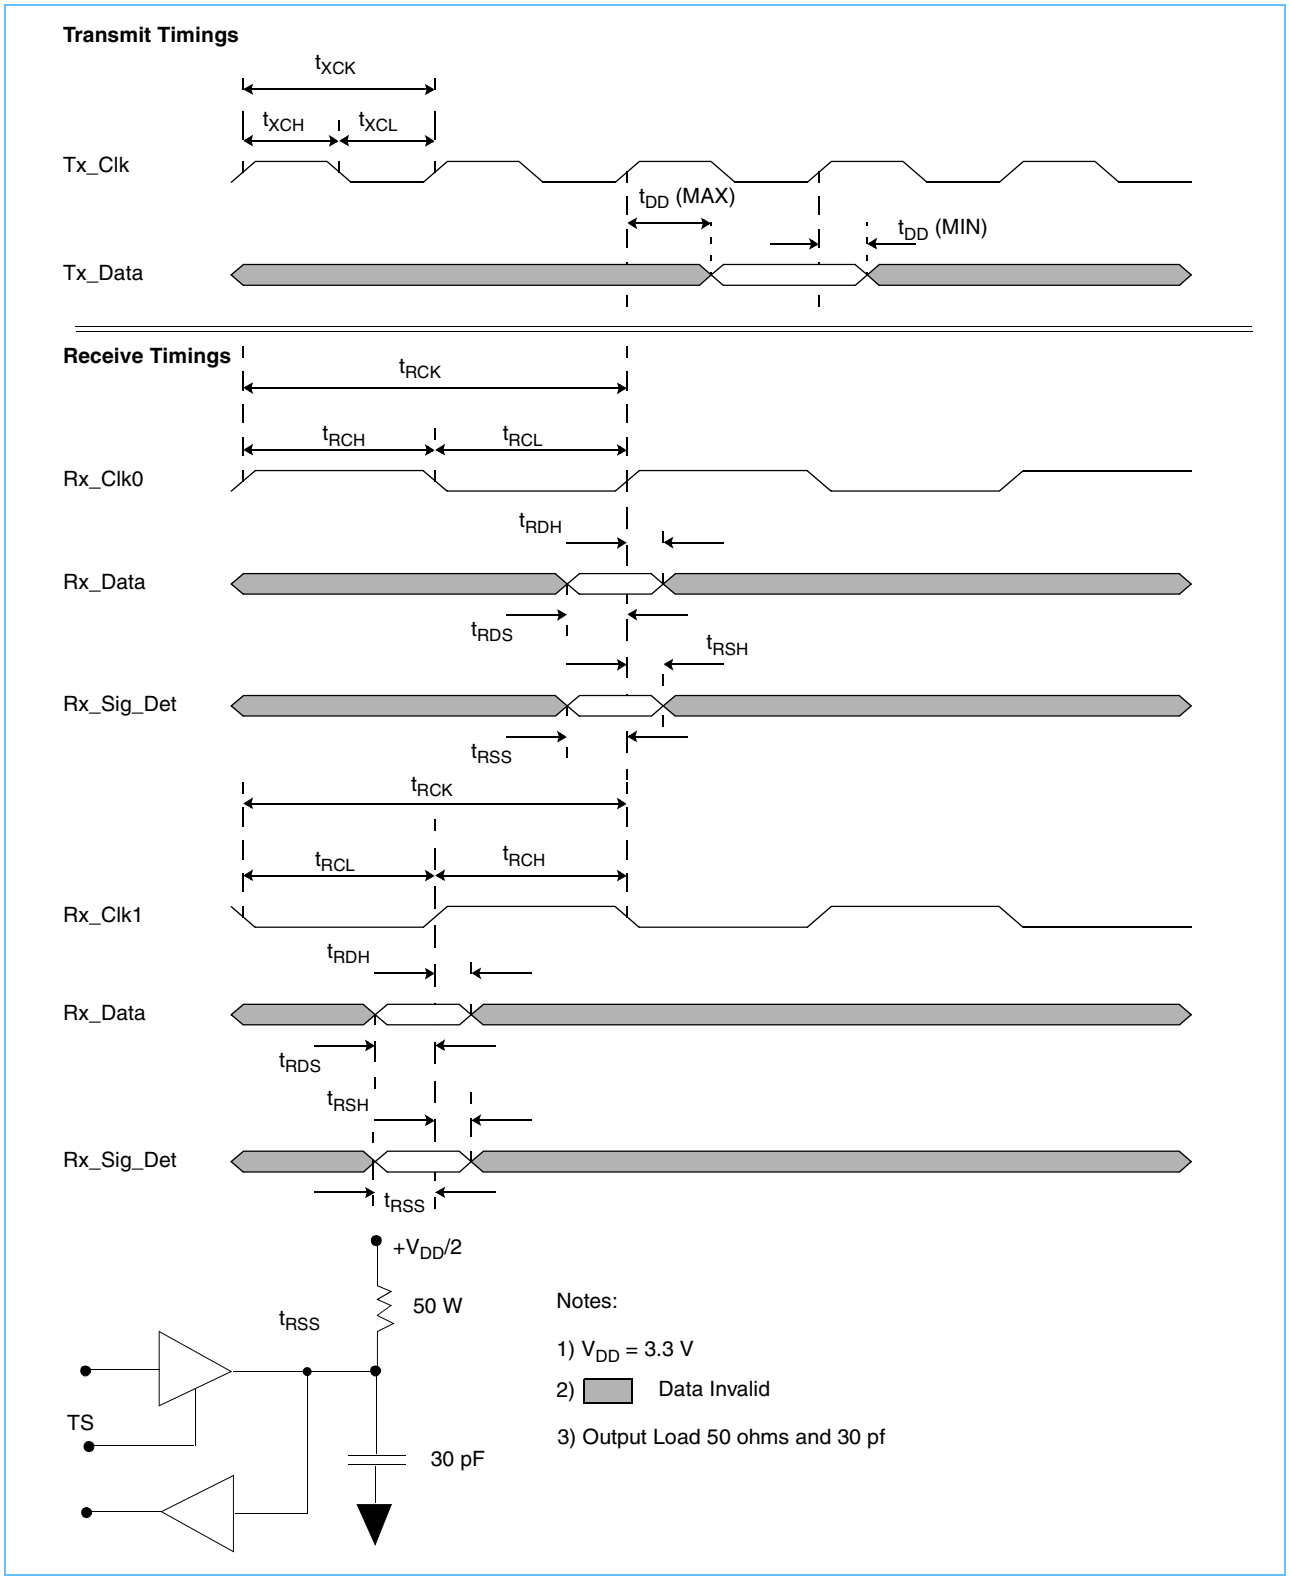


Table 2-18. TBI Timing Diagram Legend (for Figure 2-8)

Symbol	Symbol Description	Minimum (ns)	Maximum (ns)
t_{XCK}	Tx_Clk Transmit Cycle Time	8	
t_{XCH}	Tx_Clk Pulse Width High	3.5	4.0
t_{XCL}	Tx_Clk Pulse Width Low	4.0	4.5
t_{DD}	Tx_Data_(7:0) Output Delay	3.2	4.7
t_{RCK}	Rx_Clk0/Rx_Clk1 Receive Cycle Time	16	
t_{RCH}	Rx_Clk0/Rx_Clk1 Pulse Width High	7	
t_{RCL}	Rx_Clk0/Rx_Clk1 Pulse Width Low	7	
t_{RDS}	Rx_Data_(9:0) Setup Time Clk0	0.2	
t_{RDH}	Rx_Data_(9:0) Hold Time Clk0	0	
t_{RSS}	Sig_Det Setup Time Clk0	0.8	
t_{RSH}	Sig_Det Hold Time Clk0	0.9	
t_{RDS}	Rx_Data_(9:0) Setup Time Clk1	0.2	
t_{RDH}	Rx_Data_(9:0) Hold Time Clk1	0	
t_{RSS}	Sig_Det Setup Time Clk1	1.0	
t_{RSH}	Sig_Det Hold Time Clk1	0.3	

Note: All delays are measured with 1 ns slew time measured from 10-90% of input voltage.

2.1.5.2 GMII Bus Pins

Table 2-19. PMM Interface Pins: GMII Mode

Signal	Description	Type
Tx_Data(7:0)	Transmit Data. Data bus to the PHY, synchronous to Tx_Clk.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Data(7:0)	Received Data. Data bus from the PHY, synchronous to Rx_Clk.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Tx_En	Transmit data Enabled to the PHY, synchronous to Tx_Clk. 0 End of frame transmission 1 Active frame transmission	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Tx_Er	Transmit Error, synchronous to the Tx_Clk. 0 No error detected 1 Informs the PHY that MAC detected an error	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Valid_Byte	Receive valid data, synchronous to the Rx_Clk. 0 Data invalid 1 Byte of data (from the PHY) on Rx_Data is valid. For a standard GMII connection, this signal can be tied to '1' on the card.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Tx_Byte_Credit	Transmit next data value, asynchronous. 0 Do not send next data byte 1 Asserted. PHY indicates that the next Tx_Data value may be sent. For a standard GMII connection, this signal can be tied to '1' on the card.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Tx_Valid_Byte	Transmit valid data, synchronous to Tx_Clock 0 Data invalid 1 Byte of data (from the Network Processor) on Tx_Data is valid.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Clk	125 MHz Receive Medium clock generated by the PHY.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_DV	Receive Data Valid (from the PHY), synchronous to Rx_Clk. 0 End of frame transmission. 1 Active frame transmission.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Er	Receive Error, synchronous to Rx_Clk. 0 No error detected 1 Informs the MAC that PHY detected an error	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Tx_Clk	125 MHz transmit clock to the PHY. During operation, the network processor drives this signal to indicate that a transmit is in progress for this interface.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{CPDetect}}$	The Control Point card drives this signal active low to indicate its presence. When a non-Control Point card is plugged in, or this device pin is not connected, this signal should be pulled to a '1' on the card.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V

Note: The NP4GS3 supports GMII in Full-Duplex Mode only.
See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for pin directions (I/O) and definitions.

Figure 2-9. GMII Timing Diagram

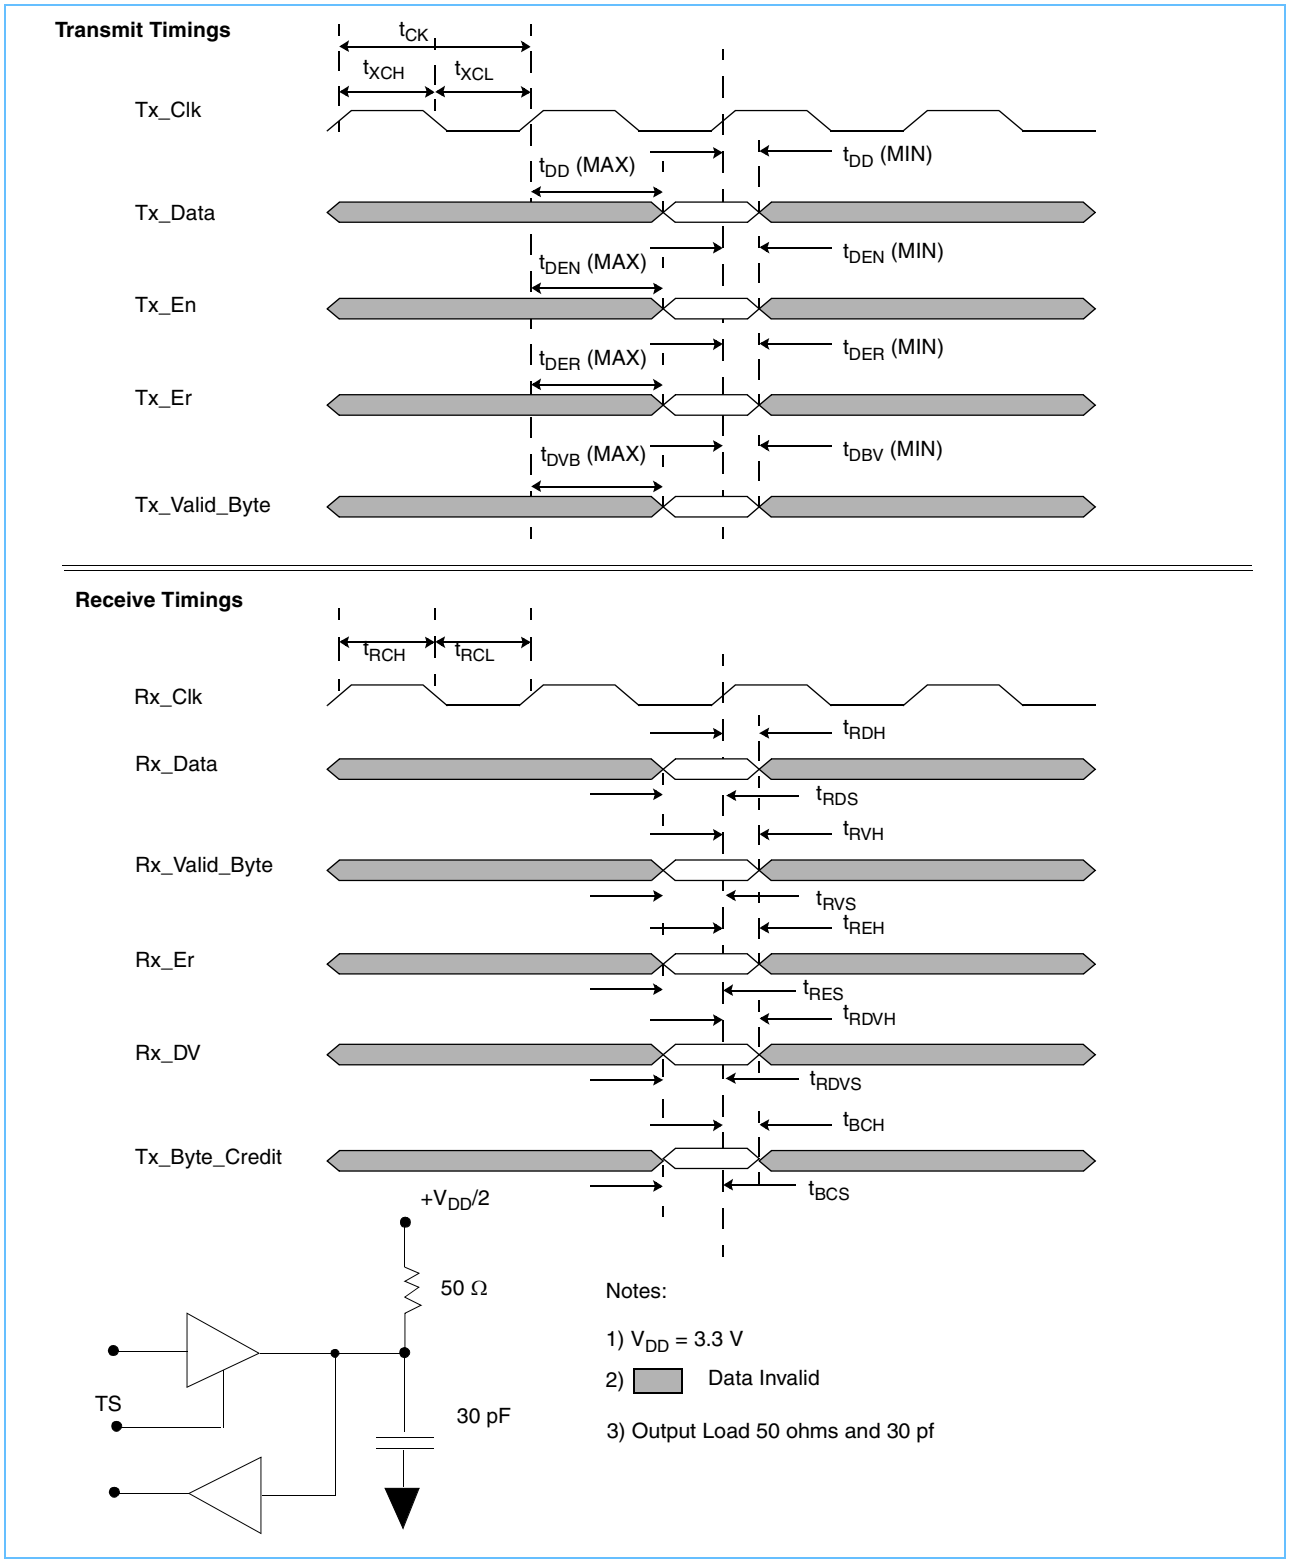

Table 2-20. GMII Timing Diagram Legend (for Figure 2-9)

Symbol	Symbol Description	Minimum (ns)	Maximum (ns)
t_{CK}	Tx_Clk Cycle Time	8	
t_{XCH}	Transmit Clock Pulse Width High	3.5	3.9
t_{XCL}	Transmit Clock Pulse Width Low	4.1	4.5
t_{RCH}	Receive Clock Pulse Width High	2.5	
t_{RCL}	Receive Clock Pulse Width Low	2.5	
t_{DD}	Tx_data Output Delay	3.7	4.6
t_{DER}	Tx_Er Output Delay	3.7	4.6
t_{DVB}	Tx_Valid_Byte Output Delay	3.7	4.4
t_{DEN}	Tx_En Output Delay	3.2	4.7
t_{RDS}	Rx_data Setup Time	1.9	
t_{RDH}	Rx_data Hold Time	0	
t_{RVS}	Rx_Valid_Byte Setup Time	1.9	
t_{RVH}	Rx_Valid_Byte Hold Time	0	
t_{RES}	Rx_Er Setup Time	1.8	
t_{REH}	Rx_Er Hold Time	0	
t_{RDVS}	Rx_DV Setup Time	1.9	
t_{RDVH}	Rx_DV Hold Time	0	
t_{BCS}	Tx_Byte_Credit Setup Time	1.9	
t_{BCH}	Tx_Byte_Credit Hold Time	0	

1. All delays are measured with 1 ns slew time measured from 10-90% of input voltage.

2.1.5.3 SMII Bus Pins

Table 2-21. PMM Interface Pins: SMII Mode

Signal	Description	Type
Tx_Data(9:0)	Transmit Data. Data bus to the PHY - contains ten streams of serial transmit data. Each serial stream is connected to a unique port. Synchronous to the common clock (Clk).	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_Data(9:0)	Received Data. Data bus from the PHY - contains ten streams of serial receive data. Each serial stream is connected to a unique port. Synchronous to the common clock (Clk).	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V

Table 2-21. PMM Interface Pins: SMII Mode

Signal	Description	Type
Sync	Asserted for one Tx_Clk cycle once every ten Tx_Clk cycles. Assertion indicates the beginning of a 10-bit segment on both Tx_Data and Rx_Data.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Sync2	Logically identical to Sync and provided for fanout purposes.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{CPDetect}}$	The Control Point card drives this signal active low to indicate its presence. When a non-Control Point card is plugged in, or this device pin is not connected, this signal should be pulled to a '1' on the card.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V

Figure 2-10. SMII Timing Diagram

Table 2-24. POS Signals (Page 1 of 2)

Signal	Description	Type
RxAddr(1:0)	Receive address bus selects a particular port in the framer for a data transfer. Valid on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
RxData (7:0) 8-bit mode (31:0) 32-bit mode	Receive POS data bus carries the frame word that is read from the Framer's FIFO. RxData transports the frame data in an 8-bit format. RxData[7:0] and [31:0] are updated on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
Clk	POS clock provides timing for the POS Framer interface. Clk must cycle at a 100 MHz or lower instantaneous rate.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{RxEnb}}$	Receive read enable controls read access from the Framer's receive interface. The framer's addressed FIFO is selected on the falling edge of RxEnb. Generated on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
RxEOF	Receive end-of-frame marks the last word of a frame in RxData. Updated on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
RxErr	Receive packet error indicates that the received packet contains an error and must be discarded. Only asserted on the last word of a packet (when RxEOF is also asserted). Updated on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
RxVal	Receive valid data output indicates the receive signals RxData, RxEOF, RxErr, and Rx_LByte are valid from the framer. Updated on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
Rx_LByte(1:0)	Receive padding length indicates the number of padding bytes included in the last word of the packet transferred in RxData. Only used when the network processor is configured in 32-bit POS mode. Updated on the rising edge of Clk. Rx_LByte(1:0) (32-bit mode) 00 packet ends on RxData(7:0) (RxData = DDDD) 01 packet ends on RxData(15:8) (RxData = DDDP) 10 packet ends on RxData(23:16) (RxData = DDPP) 11 packet ends on RxData(31:24) (RxData = DPPP)	5.0 V-tolerant 3.3 V LVTTL 3.3 V
RxPFA	Receive polled frame-available input indicates that the framers polled receive FIFO contains data. Updated on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
TxData (7:0) 8-bit mode (31:0) 32-bit mode	Transmit UTOPIA data bus carries the frame word that is written to the framer's transmit FIFO. Considered valid and written to a framer's transmit FIFO only when the transmit interface is selected by using $\overline{\text{TxEnb}}$. Sampled on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{TxEn}}$	Transmit write enable controls write access to the transmit interface. A framer port is selected on the falling edge of $\overline{\text{TxEnb}}$. Sampled on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
TxAddr(1:0)	Transmit address bus uses $\overline{\text{TxEnb}}$ to select a particular FIFO within the framer for a data transfer. Sampled on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
TxSOF	Transmit start-of-frame marks the first word of a frame in TxData. Sampled on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V

Table 2-24. POS Signals (Page 2 of 2)

Signal	Description	Type
TxEOF	Transmit end-of-frame marks the last word of a frame in TxData. Sampled on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V
TxPADL (1:0)	Transmit padding length indicates the number of padding bytes included in the last word of the packet transferred in TxData. Sampled on the rising edge of Clk. When configured in 32-bit mode the last word may contain zero, one, two or three padding bytes and only TxPADL[1:0] is used. In 8-bit mode TxPADL[1:0] is not used. TxPADL[1:0] (32-bit mode) 00 packet ends on TxData[7:0] (TxData = DDDD) 01 packet ends on TxData[15:8] (TxData = DDDP) 10 packet ends on TxData[23:16] (TxData = DDPP) 11 packet ends on TxData[31:24] (TxData = DPPP)	5.0 V-tolerant 3.3 V LVTTL 3.3 V
TxPFA	Transmit polled frame-available output indicates that the polled framer's transmit FIFO has free available space and the NP4GS3 can write data into the framer's FIFO. Updated on the rising edge of Clk.	5.0 V-tolerant 3.3 V LVTTL 3.3 V

1. All delays are measured with 1 ns slew time measured from 10-90% of input voltage.

2.1.6 PCI Pins

These pins interface with the PCI bus.

Table 2-26. PCI Pins (Page 1 of 2)

Signal	Description	Type
PCI_Clk	PCI Clock Signal (See PCI_Speed field below)	Input PCI (in)/ 3.3 V
PCI_AD(31:0)	PCI Multiplexed Address and Data Signals	Input/Output PCI (t/s) 3.3 V
$\overline{\text{PCI\_CBE}}$(3:0)	PCI Command/Byte Enable Signals	Input/Output PCI (t/s) 3.3 V
$\overline{\text{PCI\_Frame}}$	PCI Frame Signal	Input/Output PCI (s/t/s) 3.3 V
$\overline{\text{PCI\_IRdy}}$	PCI Initiator (Master) Ready Signal	Input/Output PCI (s/t/s) 3.3 V
$\overline{\text{PCI\_TRdy}}$	PCI Target (Slave) Ready Signal	Input/Output PCI (s/t/s) 3.3 V
$\overline{\text{PCI\_DevSel}}$	PCI Device Select Signal	Input/Output PCI (s/t/s) 3.3 V
$\overline{\text{PCI\_Stop}}$	PCI Stop Signal	Input/Output PCI (s/t/s) 3.3 V
$\overline{\text{PCI\_Request}}$	PCI Bus Request Signal	Output PCI (t/s) 3.3 V
$\overline{\text{PCI\_Grant}}$	PCI Bus Grant Signal	Input PCI (t/s) 3.3 V
PCI_IDSel	PCI Initialization Device Select Signal	Input PCI (in) 3.3 V
$\overline{\text{PCI\_PErr}}$	PCI Parity Error Signal	Input/Output PCI (s/t/s) 3.3 V
$\overline{\text{PCI\_SErr}}$	PCI System Error Signal	Input/Output PCI (o/d) 3.3 V
$\overline{\text{PCI\_IntA}}$	PCI Level Sensitive Interrupt	Output PCI (o/d) 3.3 V
PCI_Par	PCI Parity Signal. Covers all the data/address and the four command/BE signals.	Input/Output PCI (t/s) 3.3 V

Note: PCI I/Os are all configured for multi-point operation.

Table 2-26. PCI Pins (Page 2 of 2)

Signal	Description	Type
PCI_Speed	PCI Speed. Controls Acceptable PCI Frequency Asynchronous Range by setting the PLB/PCI clock ratio. 0 PLB:PCI Mode 2:1. Acceptable PCI Frequency Asynchronous Range is 34.5 MHz to 66.6 MHz 1 PLB:PCI Mode 3:1. Acceptable PCI Frequency Asynchronous Range is 23.5 MHz to 44.5 MHz	Input 3.3 V-tolerant 2.5 V 2.5 V
PCI_Bus_NM_Int	External Non-maskable Interrupt - the active polarity of the interrupt is programmable by the PowerPC.	Input PCI 3.3 V
PCI_Bus_M_Int	External Maskable Interrupt - the active polarity of the interrupt is programmable by the PowerPC.	Input PCI 3.3 V
Note: PCI I/Os are all configured for multi-point operation.		

Figure 2-13. PCI Timing Diagram

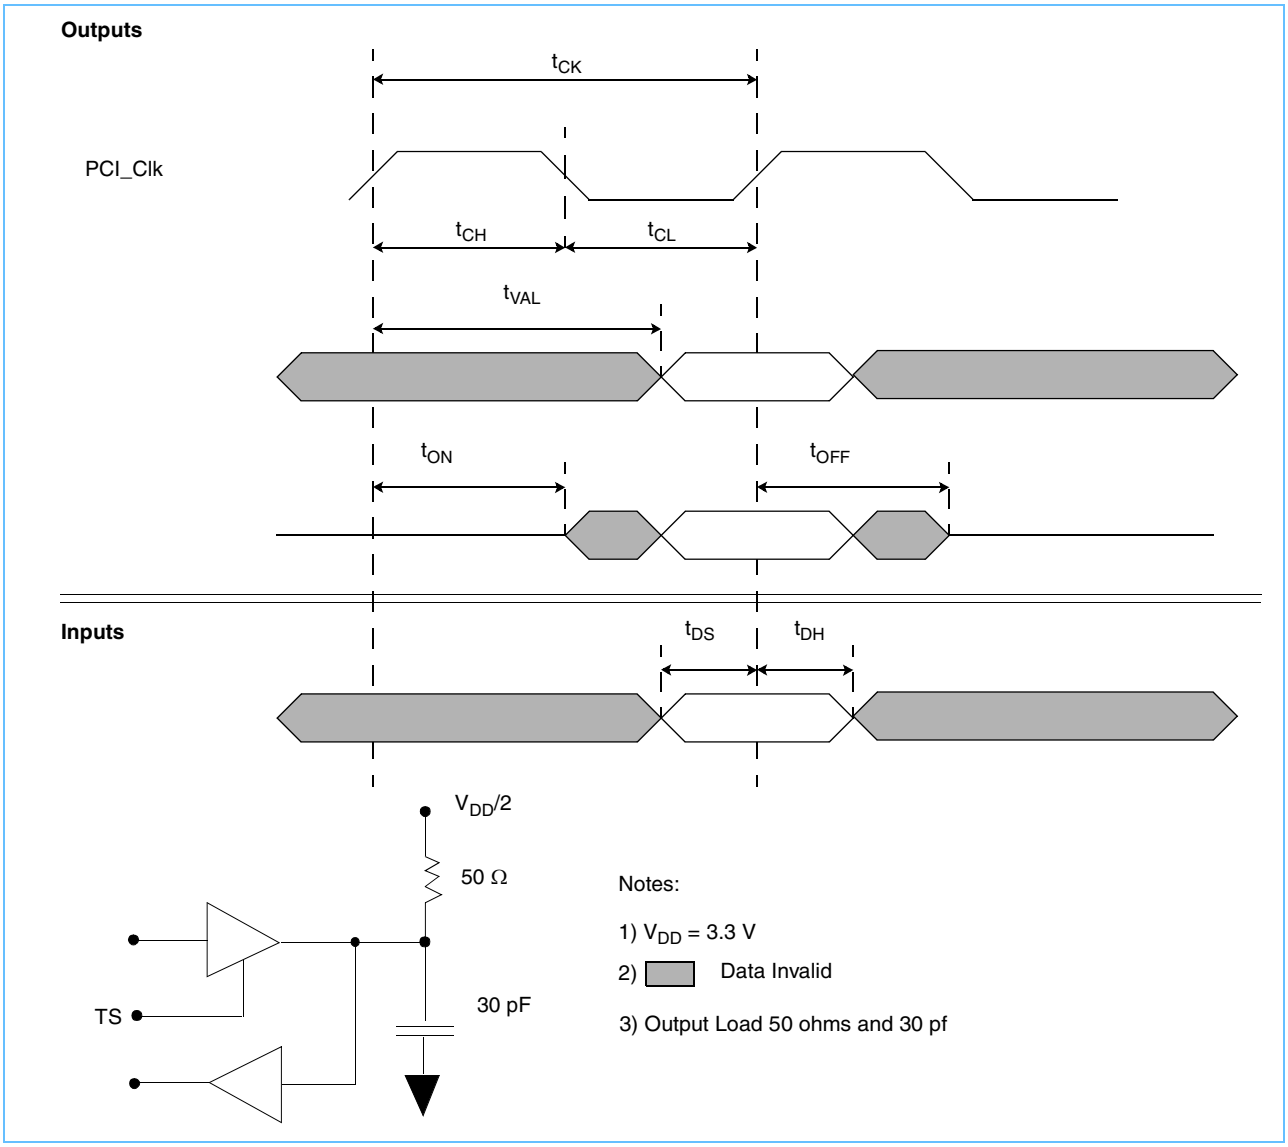

Table 2-27. PCI Timing Diagram Legend (for Figure 2-13)

Symbol	Symbol Description	Minimum (ns)	Maximum (ns)
t_{CK}	PCI Cycle Time	15	
t_{CH}	Clk Clock Width High	7.5	
t_{CL}	Clk Clock Width Low	7.5	
t_{VAL}	Worst Case Output Delay	2.0	4.8
t_{ON}	PCI Bus Turn on Output Delay	2	
t_{OFF}	PCI Bus Turn off Output Delay		14
t_{DS}	Input Setup Time	2.4	
t_{DH}	Input Hold Time	0	

Note: All delays are measured with 1 ns slew time measured from 10-90% of input voltage.

2.1.7 Management Bus Interface Pins

The signals from these pins are translated into various “host” buses by an external field-programmable gate array (FPGA) Serial/Parallel Manager (SPM).

Table 2-28. Management Bus Pins

Signal	Description	Type
MG_Data	Serial Data. Supports Address/Control/Data protocol.	Input/Output 3.3 V-tolerant 2.5 V 2.5 V
MG_Clk	33.33 MHz clock	Output 3.3 V-tolerant 2.5 V 2.5 V
MG_nIntr	Rising-edge sensitive interrupt input	Input 3.3 V-tolerant 2.5 V 2.5 V

Figure 2-14. SPM Bus Timing Diagram

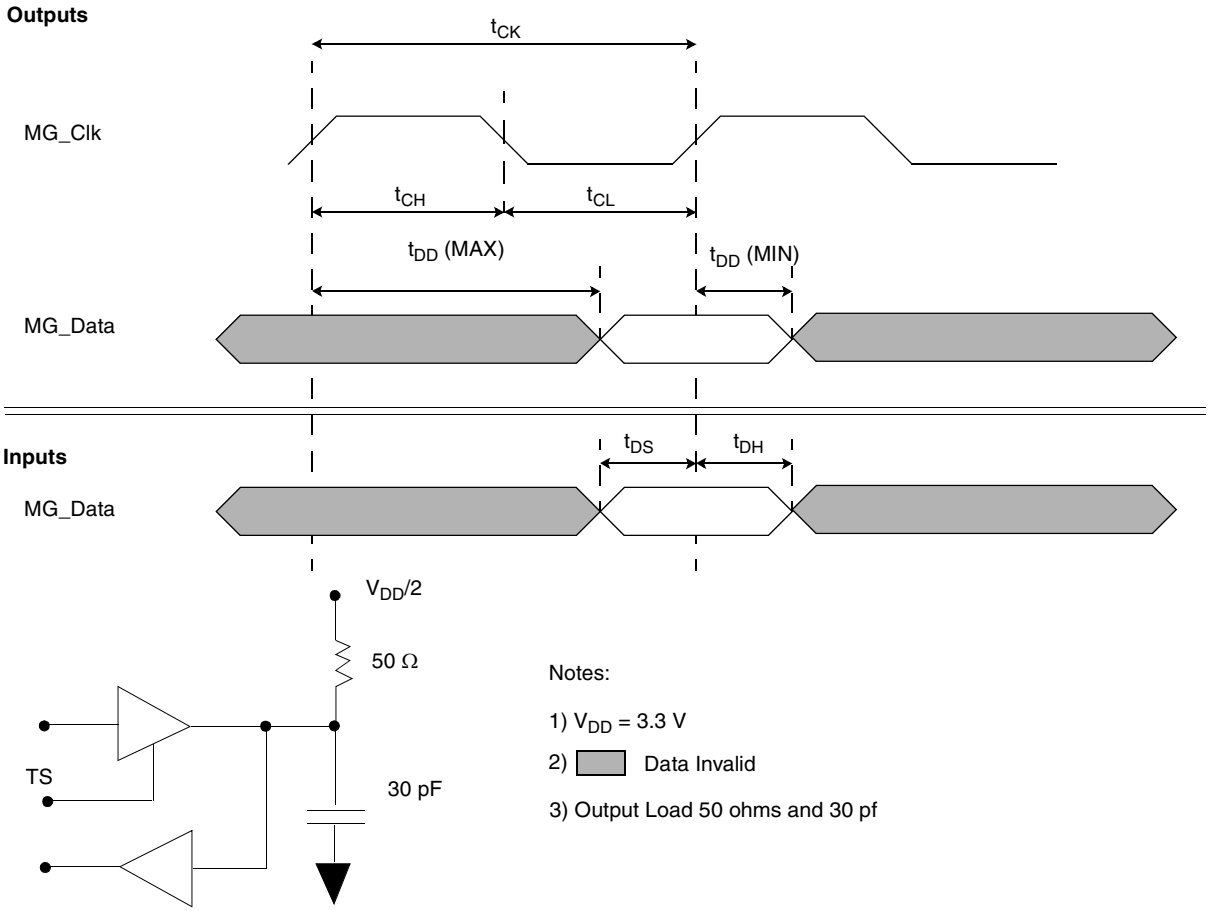

Table 2-29. SPM Bus Timing Diagram Legend (for Figure 2-14)

Symbol	Symbol Description	Minimum (ns)	Maximum (ns)
t_{CK}	SPM Cycle Time	30	
t_{CH}	Clock Pulse Width High	14.4	15.6
t_{CL}	Clock Pulse Width Low	14.4	15.6
t_{DD}	Data Output Delay	6.9	7.9
t_{DS}	Data Setup Time	5.1	
t_{DH}	Data Hold Time	0	

Note: mg_nintr is an asynchronous input and is not timed.
All delays are measured with 1 ns slew time measured from 10-90% of input voltage.

2.1.8 Miscellaneous Pins

Table 2-30. Miscellaneous Pins (Page 1 of 2)

Signal	Description	Type
Switch_Clock_A	The positive pin of an input differential pair. 50.6875 to 62.5 MHz. Generates Packet Routing Switch clock domains. Required to have cycle-to-cycle jitter ≤ ±150 ps. Duty Cycle tolerance must be ≤ ±10%. An on-chip differential terminator of 100 ohms is present between this pin and its complement pin.	Input LVDS 1.5 V
$\overline{\text{Switch\_Clock\_A}}$	The negative pin of an input differential pair. 50.6875 to 62.5 MHz.	Input LVDS 1.5 V
Switch_Clock_B	The positive pin of an input differential pair. 50.6875 to 62.5 MHz. Generates Packet Routing Switch clock domains. Required to have cycle-to-cycle jitter ≤ ±150 ps. Duty Cycle tolerance must be ≤ ±10%. An on-chip differential terminator of 100 ohms is present between this pin and its complement pin.	Input LVDS 1.5 V
$\overline{\text{Switch\_Clock\_B}}$	The negative pin of an input differential pair. 50.6875 to 62.5 MHz.	Input LVDS 1.5 V
Switch_BNA	Selects which of the two DASL ports (A or B) carries network traffic. 0 Port A carries the network traffic 1 Port B carries the network traffic	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Core_Clock	53.33 MHz oscillator - generates 266 /133 clock domains. Required to have cycle-to-cycle jitter ≤ ±150 ps. Duty Cycle tolerance must be ≤ ±5%.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Clock125	125 MHz oscillator. Required to have cycle-to-cycle jitter ≤ ±60 ps. Duty Cycle tolerance must be ≤ ± 5%. This clock is required only when supporting TBI and GMII DMU bus modes.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{Blade\_Reset}}$	Reset NP4GS3 - signal must be driven active low for a minimum of 1µs to ensure a proper reset of the NP4GS3. All input clocks (Switch_Clock_A, $\overline{\text{Switch\_Clock\_A}}$, Switch_Clock_B, $\overline{\text{Switch\_Clock\_B}}$, Core_Clock, Clock125 if in use, and PCI_Clk) must be running prior to the activation of this signal.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{Operational}}$	NP4GS3 operational - pin is driven active low when both the NP4GS3 Ingress and Egress Macros have completed their initialization. It remains active until a subsequent $\overline{\text{Blade\_Reset}}$ is issued.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V
Testmode(1:0)	00 Functional Mode, including concurrent use of the JTAG interface for RISCWatch or CABWatch operations. 01 Debug Mode - Debug mode must be indicated by the Testmode I/O for debug bus (DMU_D) output to be gated from the probe. 10 JTAG Test Mode 11 LSSD Test Mode	Input CMOS 1.8 V
$\overline{\text{JTAG\_TRst}}$	JTAG test reset. For normal functional operation, this pin must be connected to the same card source that is connected to the $\overline{\text{Blade\_Reset}}$ input. When the JTAG interface is used for JTAG test functions, this pin is controlled by the JTAG interface logic on the card.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
JTAG_TMS	JTAG test mode select. For normal functional operation, this pin should be tied either low or high.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
JTAG_TDO	JTAG test data out. For normal functional operation, this pin should be tied either low or high.	Output 5.0 V-tolerant 3.3 V LVTTL 3.3 V

Table 2-30. Miscellaneous Pins (Page 2 of 2)

Signal	Description	Type
JTAG_TDI	JTAG test data in. For normal functional operation, this pin should be tied either low or high.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
JTAG_TCk	JTAG test clock. For normal functional operation, this pin should be tied either low or high.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
PLLA_V_{DD} PLLB_V_{DD} PLLC_V_{DD}	These pins serve as the +1.8 Volt supply for a critical noise-sensitive portion of the phase-locked loop (PLL) circuits. One pin serves as the analog V_{DD} for each PLL circuit. To prevent noise on these pins from introducing phase jitter in the PLL outputs, place filters at the board level to isolate these pins from the noisy digital V_{DD} pins. Place separate filters on each analog V_{DD} pin to prevent noise from one PLL being introduced into another. See section *2.1.9 PLL Filter Circuit on page 80* for filter circuit details.	Input PLL_V_{DD} 1.8 V
PLLA_GND PLLB_GND PLLC_GND	These pins serve as the ground connection for the critical noise portion of the phase lock loop (PLL). One pin serves as the analog GND for each PLL circuit. Each should be connected to the digital ground plane at the V_{DDA} node of the PLL filter capacitor shown in *Figure 2-15: PLL Filter Circuit Diagram* on page 80.	Input PLL_GND 0.0 V
Thermal_In	Input pad of the thermal monitor (resistor). See *2.1.10 Thermal I/O Usage* on page 80 for details on thermal monitor usage	Thermal
Thermal_Out	Output pad of the thermal monitor (resistor)	Thermal
VRef1(2), VRef2(8,7,6)	Voltage reference for SSTL2 I/Os for D1, D2, and D3 (approximately four pins per side of the device that contains SSTL2 I/O)	Input VRef 1.25 V
VRef1(1), VRef2(5,4,3)	Voltage reference for SSTL2 I/Os for D4 and D6 (approximately four pins per side of the device that contains SSTL2 I/O)	Input VRef 1.25 V
VRef1(0), VRef2(2,1,0)	Voltage reference for SSTL2 I/Os for DS0 and DS1 (approximately four pins per side of the device that contains SSTL2 I/O)	Input VRef 1.25 V
Boot_Picocode	Determines location of network processor picocode load location. 0 Load from SPM 1 Load from external source (typically Power PC or PCI bus)	Input 3.3 V-tolerant 2.5 V 2.5 V
Boot_PPC	Determines location of Power PC code start location. 0 Start from D6 1 Start from PCI	Input 3.3 V-tolerant 2.5 V 2.5 V
Spare_Tst_Rcvr(9:0)	Unused signals needed for Manufacturing Test. Spare_Tst_Rcvr (9:5,1) should be tied to 0 on the card. Spare_Tst_Rcvr (4:2,0) should be tied to 1 on the card.	Input CMOS 1.8 V
$\overline{\text{C405\_Debug\_Halt}}$	This signal, when asserted low, forces the embedded PowerPC 405 processor to stop processing all instructions. For normal functional operation, this signal should be tied inactive high.	Input 5.0 V-tolerant 3.3 V LVTTL 3.3 V
$\overline{\text{PIO(2:0)}}$	Programmable I/O [NP4GS3B (R2.0))]	Input/Output CMOS 2.5V

Table 2-31. Signals Requiring Pull-Up or Pull-Down

Signal Name	Function	Value
Signals requiring a DC connection that is the same value for all applications		
Testmode(1:0)		Pull-down
JTAG_TDI		Pull-up
JTAG_TMS		Pull-up
JTAG_TCk		Pull-up
$\overline{\text{C405\_Debug\_Halt}}$		Pull-up
Spare_Tst_Rcvr (9:5, 1)		Pull-down
Spare_Tst_Rcvr (4:2, 0)		Pull-up
Signals requiring a DC connection that varies across different applications		
Multicast_Grant_A, Multicast_Grant_B		Pull-up if no system device drives this signal
RES_Data		Pull-down if no other system device drives this signal
PCI_Speed		Choose up or down based on system PCI bus speed
MG_nIntr		Pull-down if no system device drives this signal
MG_Data		Pull-down when external SPM module is attached
Boot_Picocode		Choose up or down based on picocode load location
Boot_PPC		Choose up or down based on PPC code load location
Switch_BNA		Pull-up if no system device drives this signal
Signals which have an AC connection, but also require pull-up or pull-down		
$\overline{\text{Operational}}$		Pull-up
DMU_A(0), DMU_B(0), DMU_C(0), DMU_D(0)	$\overline{\text{CPDetect}}$	If control point blade then pull-down, otherwise pull-up
DMU_A(30:29), DMU_B(30:29), DMU_C(30:29), DMU_D(30:29)	DMU in 8-bit POS mode. RxAddr (1:0)	Pull-down
DMU_A(4), DMU_B(4), DMU_C(4), DMU_D(4)	DMU in any POS mode. RxVal	Pull-down
D3_DQS(1:0), D2_DQS(1:0), D1_DQS(1:0)		Pull-down
D0_DQS(3:0), D4_DQS(3:0), D6_DQS(3:0)		Pull-down
DS0_DQS(3:0), DS1_DQS(3:0)		Pull-down

2.1.9 PLL Filter Circuit

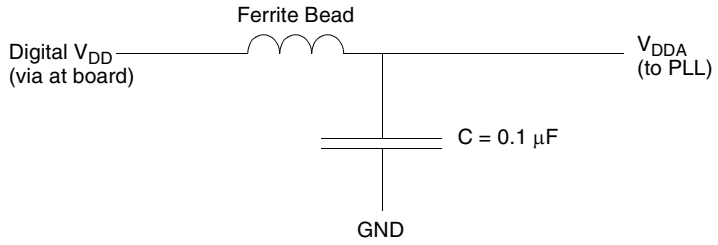
V_{DDA} is the voltage supply pin to the analog circuits in the PLL. Noise on V_{DDA} causes phase jitter at the output of the PLL. V_{DDA} is brought to a package pin to isolate it from the noisy internal digital V_{DD} signal. If little noise is expected at the board level, then V_{DDA} can be connected directly to the digital V_{DD} plane. In most circumstances, however, it is prudent to place a filter circuit on the V_{DDA} as shown below.

Note: All wire lengths should be kept as short as possible to minimize coupling from other signals.

The impedance of the ferrite bead should be much greater than that of the capacitor at frequencies where noise is expected. Many applications have found that a resistor does a better job of reducing jitter than a ferrite bead does. The resistor should be kept to a value lower than 2Ω. Experimentation is the best way to determine the optimal filter design for a specific application.

Note: One filter circuit may be used for PLLA and PLLB, and a second filter circuit should be used for PLLC.

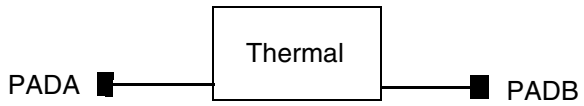
Figure 2-15. PLL Filter Circuit Diagram



2.1.10 Thermal I/O Usage

The thermal monitor consists of a resistor connected between pins PADA and PADB. At 25°C this resistance is estimated at 1290 + 350 ohms. The published temperature coefficient of the resistance for this technology is 0.33% per °C. To determine the actual temperature coefficient, see *Measurement Calibration* on page 81.

Figure 2-16. Thermal Monitor



Note: There is an electrostatic discharge (ESD) diode at PADA and PADB.

2.1.10.1 Temperature Calculation

The chip temperature can be calculated from

$$T_{chip} = \frac{1}{t_c (R_{measured} - R_{calibrated})} + T_{calibrated}\ °C$$

where:

$R_{measured}$ = resistance measured between PADA and PADB at test temperature.

$R_{calibrated}$ = resistance measured between PADA and PADB (V r /I dc) at known temperature.

$T_{calibrated}$ = known temperature used to measure R calibrated.

2.1.10.2 Measurement Calibration

To use this thermal monitor accurately, it must first be calibrated. To calibrate, measure the voltage drop at two different known temperatures at the package while the device is dissipating little (less than 100 mW) or no power. Apply I_{dc} and wait for a fixed time t_m, where t_m = approximately 1 ms. Keep t_m short to minimize heating effects on the thermal monitor resistance. Then measure V_r. Next, turn off I_{dc} and change the package temperature. Reapply I_{dc}, wait t_m again and measure V_r.

The temperature coefficient is,

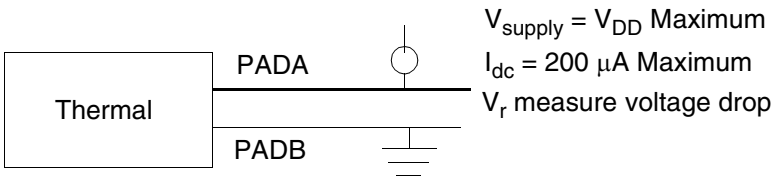
$$Tc = \left[\frac{\Delta Vr}{Idc \times \Delta T}\right]\frac{\Omega}{°C} \quad ,$$

where:

ΔT = temperature change, °C

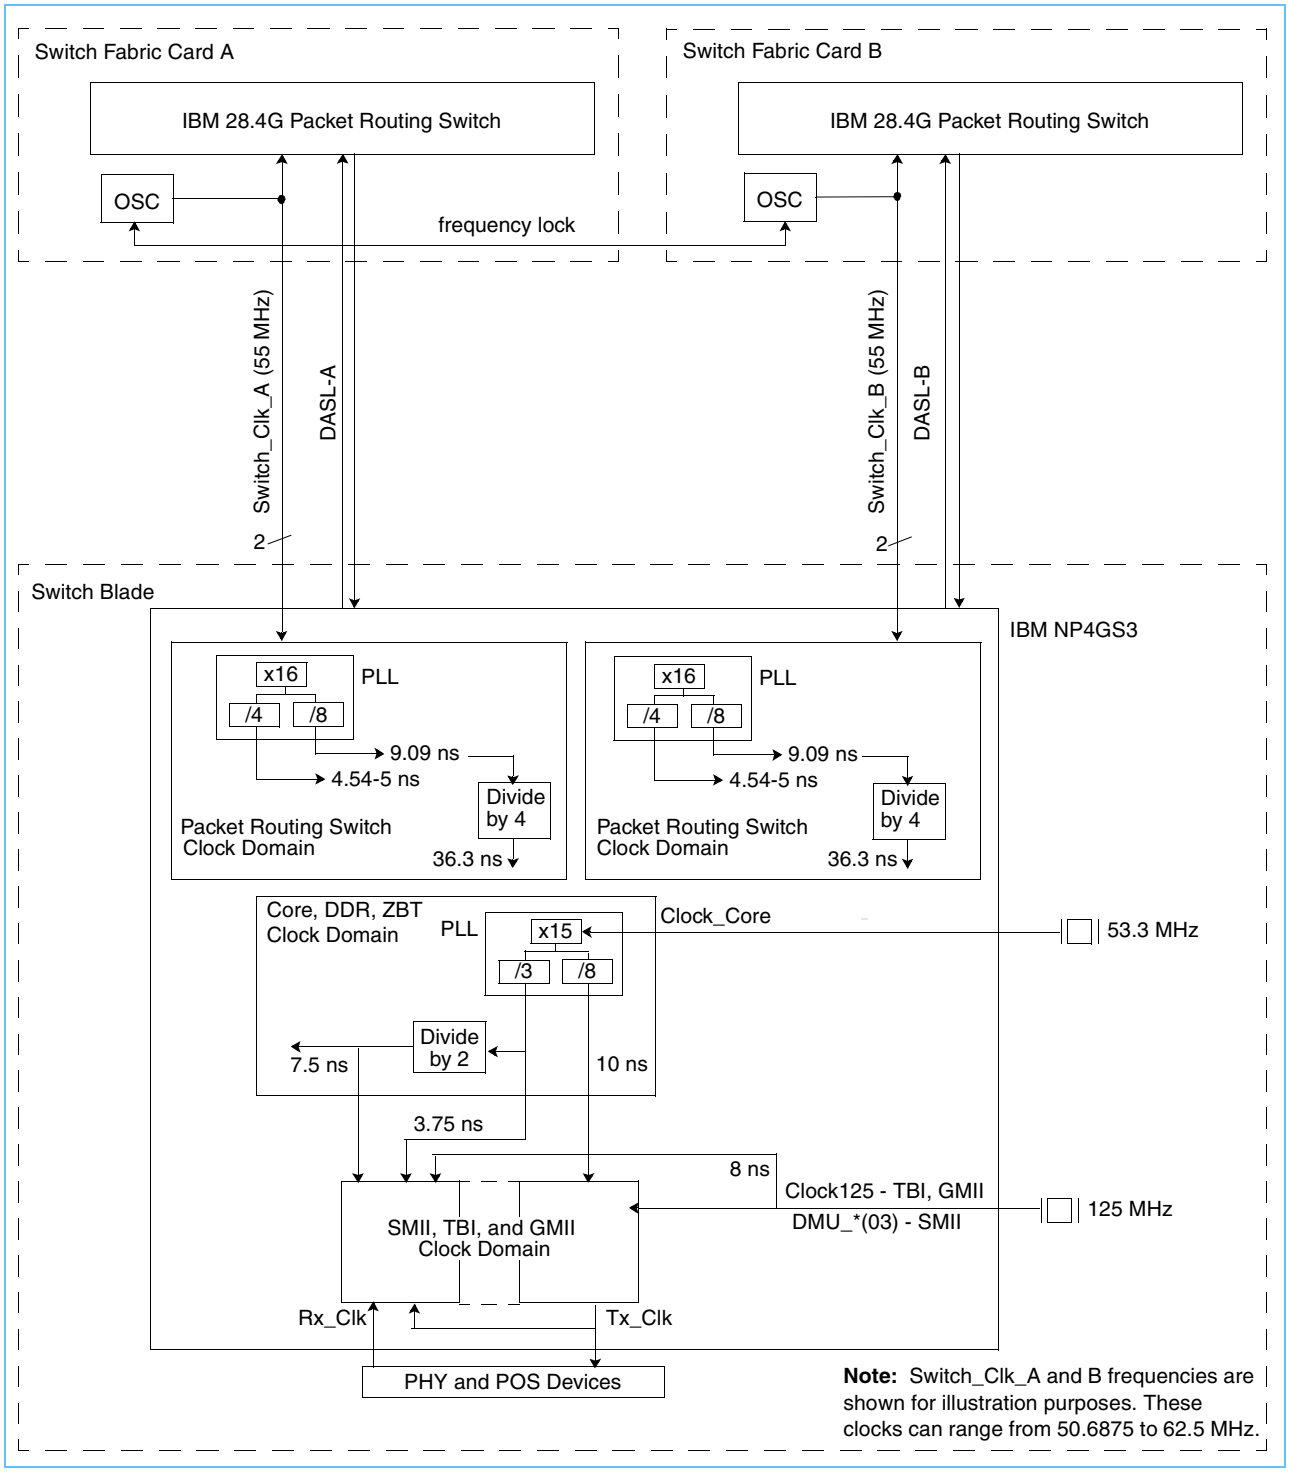
ΔV_r = voltage drop, V

I_{dc} = applied current, A



2.2 Clocking Domains

Figure 2-17. Clock Generation and Distribution



See *NP4GS3 DMU Bus Clock Connections* on page 56 and *NP4GS3 DMU Bus Clock Connections (POS Overview)* on page 57 for related clock information.

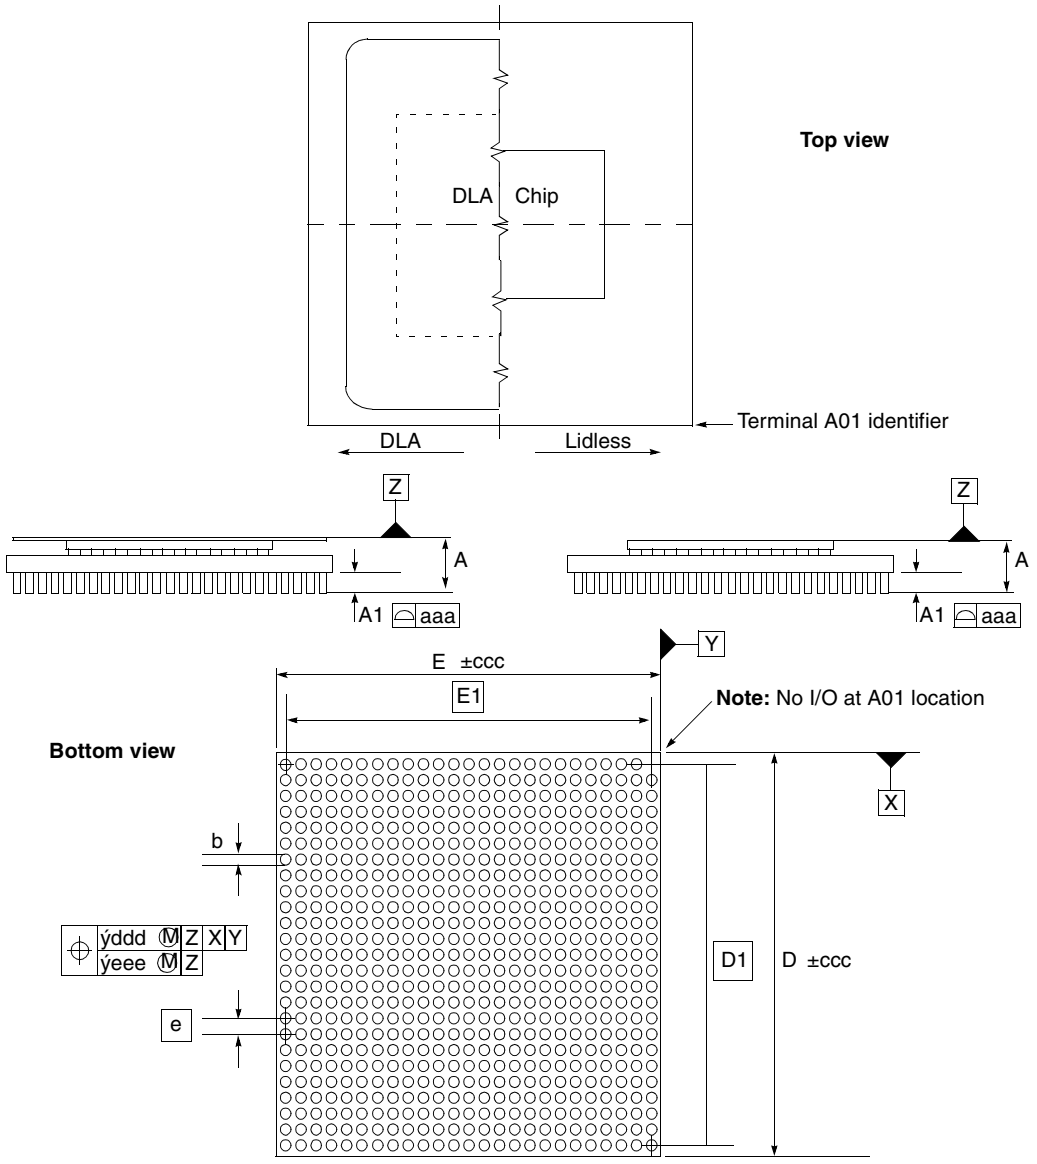
2.3 Mechanical Specifications

Figure 2-19. Mechanical Diagram



Notes:

1. Refer to *Table 2-32* on page 85 for mechanical dimensions.
2. Mechanical drawing is not to scale. See your IBM representative for more information.
3. IBM square outline conforms to JEDEC MO-158.

Table 2-32. Mechanical Specifications

Mechanical Dimensions		Value[1]
A (DLA)	Min[2]	6.23
	Max[3]	6.83
A (Lidless)	Min[2]	4.23
	Max[3]	4.83
A1	Nom	2.21
b	Min	0.48
	Max	0.52
e	Basic	1.27
aaa		0.15
ccc		0.20
ddd		0.30
eee		0.10
D		42.50
D1		40.64
E		42.50
E1		40.64
M[4]		33 x 33
N[5]		1088[5]
Weight (g)		TBD

1. All dimensions are in millimeters, except where noted.
2. Minimum package thickness is calculated using the nominal thickness of all parts. The nominal thickness of an 8-layer package was used for the package thickness.
3. Maximum package thickness is calculated using the nominal thickness of all parts. The nominal thickness of a 12-layer package was used for the package thickness.
4. M = the I/O matrix size.
5. N = the maximum number of I/Os. The number of I/Os shown in the table is the amount after depopulation. Product with 1.27 mm pitch is depopulated by one I/O at the A01 corner of the array.
6. IBM square outline conforms to JEDEC MO-158.

2.4 Signal Pin Lists

Note: All unused pins should be left unconnected on the card.

Table 2-33. Complete Signal Pin Listing by Signal Name (Page 1 of 10)

Signal Name	Grid Position	Signal Name	Grid Position	Signal Name	Grid Position

2.5 IEEE 1149 (JTAG) Compliance

2.5.1 Statement of JTAG Compliance

The NP4GS3 is compliant with IEEE Standard 1149.1a.

2.5.2 JTAG Compliance Mode

Compliance with IEEE 1149.1a is enabled by applying a compliance-enable pattern to the compliance-enable inputs as shown in *Table 2-35*.

Table 2-35. JTAG Compliance-Enable Inputs

Compliance-Enable Inputs	Compliance-Enable Pattern
Testmode(1:0)	'10'
Spare_Tst_Rcvr(9)	1
Spare_Tst_Rcvr(4)	1
Spare_Tst_Rcvr(3)	1
Spare_Tst_Rcvr(2)	1

Note: To achieve reset of the JTAG test logic, the JTAG_TRst input must be driven low when the compliance-enable pattern is applied.

2.5.3 JTAG Implementation Specifics

All mandatory JTAG public instructions are implemented in the NP4GS3's design. *Table 2-36* documents all implemented public instructions.

Table 2-36. Implemented JTAG Public Instructions

Instruction Name	Binary Code	[1] Serial Data Reg connected to TDI/TDO	I/O Control Source (driver data and driver enable)
BYPASS	111 1111	Bypass	System, functional values
CLAMP	111 1101	Bypass	JTAG
EXTEST	111 1000	BoundaryScan	JTAG
HIGHZ	111 1010	Bypass	JTAG, all drivers disabled
SAMPLE/PRELOAD	111 1001	BoundaryScan	System, functional values

1. Device TDO output driver is only enabled during TAP Controller states Shift_IR and Shift_DR.

2.5.4 Brief Overview of JTAG Instructions

Instruction	Description
BYPASS	Connects the bypass data register between the TDI and TDO pins. The bypass data register is a single shift-register stage that provides a minimum-length serial path between the TDI and TDO pins when no test operation of the device is required. Bypass does not disturb the normal functional connection and control of the I/O pins.

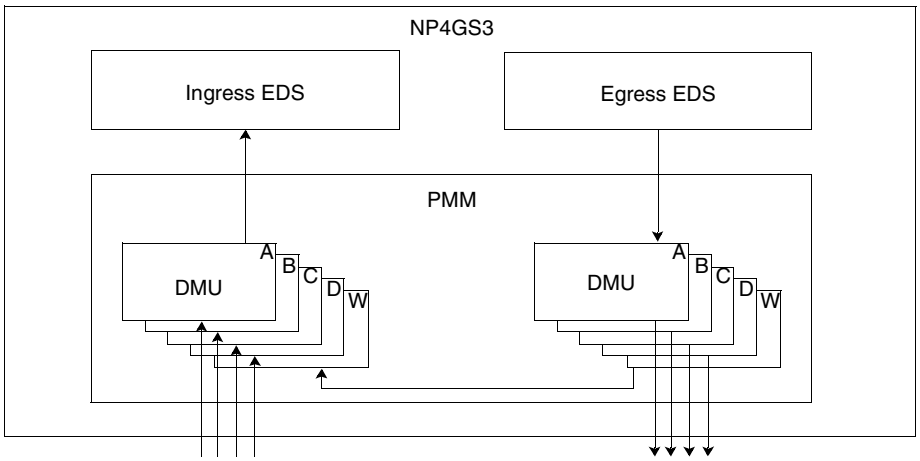
Instruction	Description
CLAMP	Causes all output pins to be driven from the corresponding JTAG parallel boundary scan register. The SAMPLE/PRELOAD instruction is typically used to load the desired values into the parallel boundary scan register. Since the clamp instruction causes the serial TDI/TDO path to be connected to the bypass data registers, scanning through the device is very fast when the clamp instruction is loaded.
EXTEST	Allows the JTAG logic to control output pin values by connecting each output data and enable signal to its corresponding parallel boundary scan register. The desired controlling values for the output data and enable signals are shifted into the scan boundary scan register during the shiftDR state. The parallel boundary scan register is loaded from the scan boundary scan register during the updateDR state. The EXTEST instruction also allows the JTAG logic to sample input receiver and output enable values. The values are loaded into the scan boundary scan register during captureDR state.
HIGHZ	Causes the JTAG logic to tri-state all output drivers while connecting the bypass register in the serial TDI/TDO path.
SAMPLE/PRELOAD	Allows the JTAG logic to sample input pin values and load the parallel boundary scan register without disturbing the normal functional connection and control of the I/O pins. The sample phase of the instruction occurs in captureDR state, at which time the scan boundary scan register is loaded with the corresponding input receiver and output enable values. (Note that for input pins that are connected to a common I/O, the scan boundary scan register only updates with a input receiver sample if the corresponding output driver of the common I/O is disabled; otherwise the scan register is updated with the output data signal.) The desired controlling values for the output pins are shifted into the scan boundary scan register during the shiftDR state and loaded from the scan boundary scan register to the parallel boundary scan register during the updateDR state.

3. Physical MAC Multiplexer

The Physical MAC Multiplexer (PMM) moves data between physical layer devices and the network processor. The PMM interfaces with the network processor's external ports in the ingress (I-PMM) and egress (E-PMM) directions.

The PMM includes five Data Mover Units (DMUs), as illustrated in *Figure 3-1*. Four DMUs (A, B, C, and D) can each be independently configured as an Ethernet Medium Access Control (MAC) or a packet over SONET (POS) MAC. The device keeps a complete set of performance statistics on a per-port basis in either mode. Each DMU moves data at 1 Gigabit per second (Gbps) in both the ingress and the egress directions. The Wrap DMU enables traffic generated by the NP4GS3's egress side to move to the ingress side of the device and up to the switch fabric.

Figure 3-1. PMM Overview

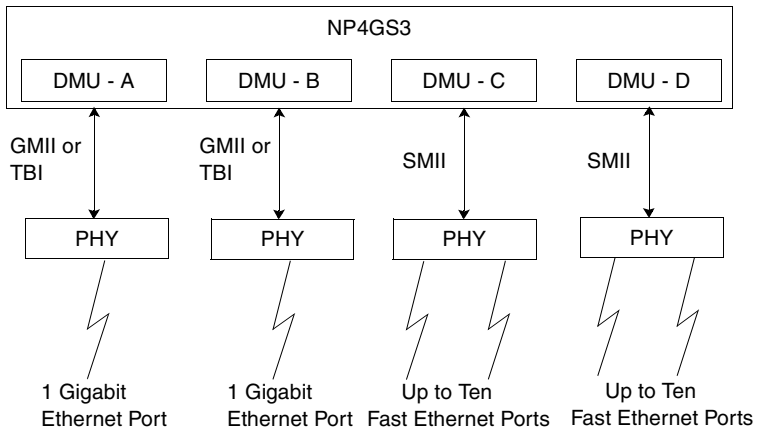


3.1 Ethernet Overview

A DMU configured in Ethernet mode can support either one port of Gigabit Ethernet or ten ports of Fast (10/100) Ethernet. When in Gigabit Ethernet mode, each DMU can be configured with either a Gigabit Media-Independent Interface (GMII) or a Ten-Bit Interface (TBI). When in Fast Ethernet mode, each DMU can be configured with a Serial Media-Independent Interface (SMII). In this mode, the single DMU MAC can be configured as ten ports. Each of these four DMUs can be configured in any of the Ethernet operation modes.

Figure 3-2: Ethernet Mode on page 110 shows a sample NP4GS3 with the PMM configured for Ethernet interfaces. DMUs A and B are configured as Gigabit Ethernet MACs. DMUs C and D are configured as Fast Ethernet MACs.

Figure 3-2. Ethernet Mode



3.1.1 Ethernet Interface Timing Diagrams

The following figures show timing diagrams for the Ethernet interfaces:

- *Figure 3-3: SMII Timing Diagram* on page 111
- *Figure 3-4: GMII Timing Diagram* on page 111
- *Figure 3-5: TBI Timing Diagram* on page 112
- *Figure 3-6: GMII POS Mode Timing Diagram* on page 113.

Figure 3-3. SMII Timing Diagram

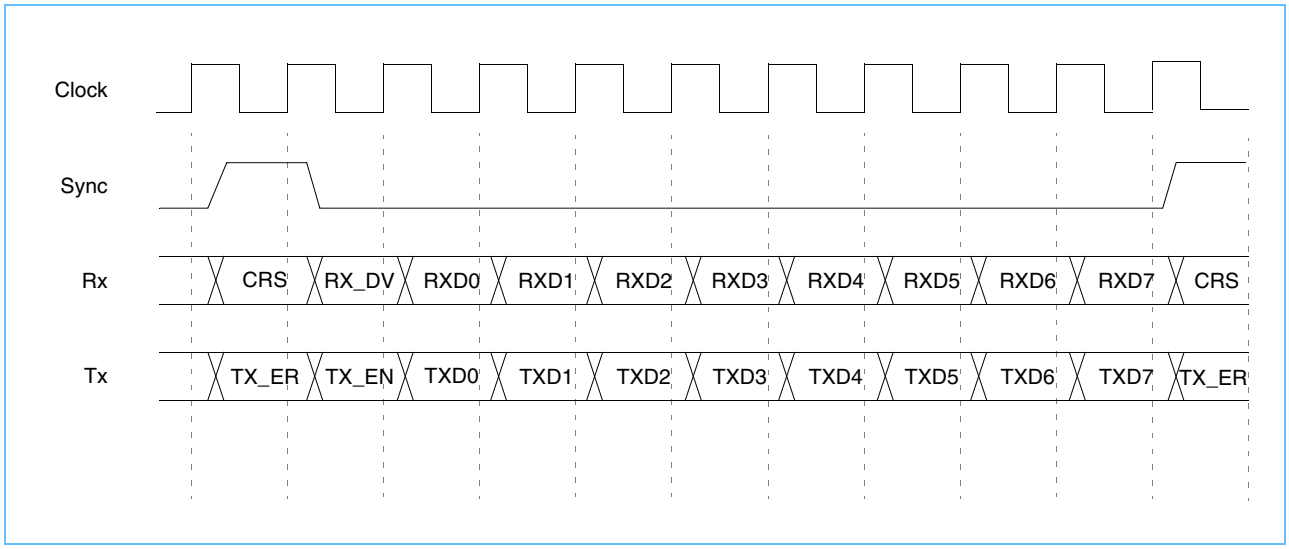


Figure 3-4. GMII Timing Diagram

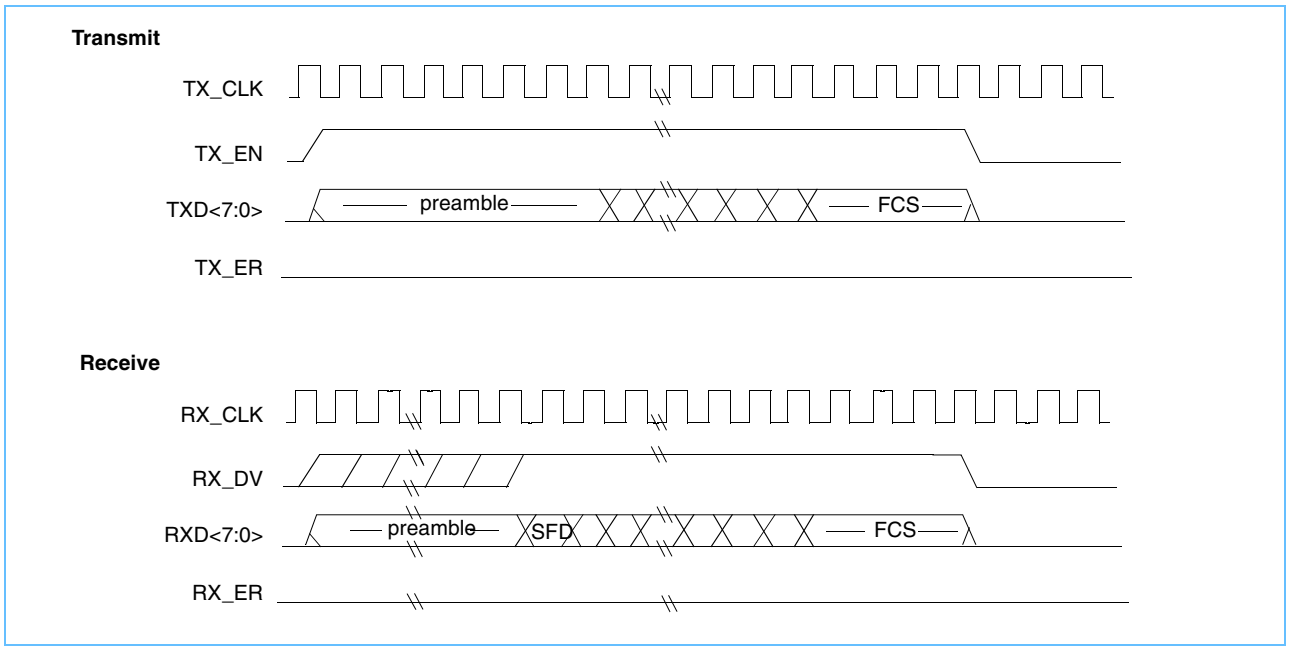

Figure 3-5. TBI Timing Diagram

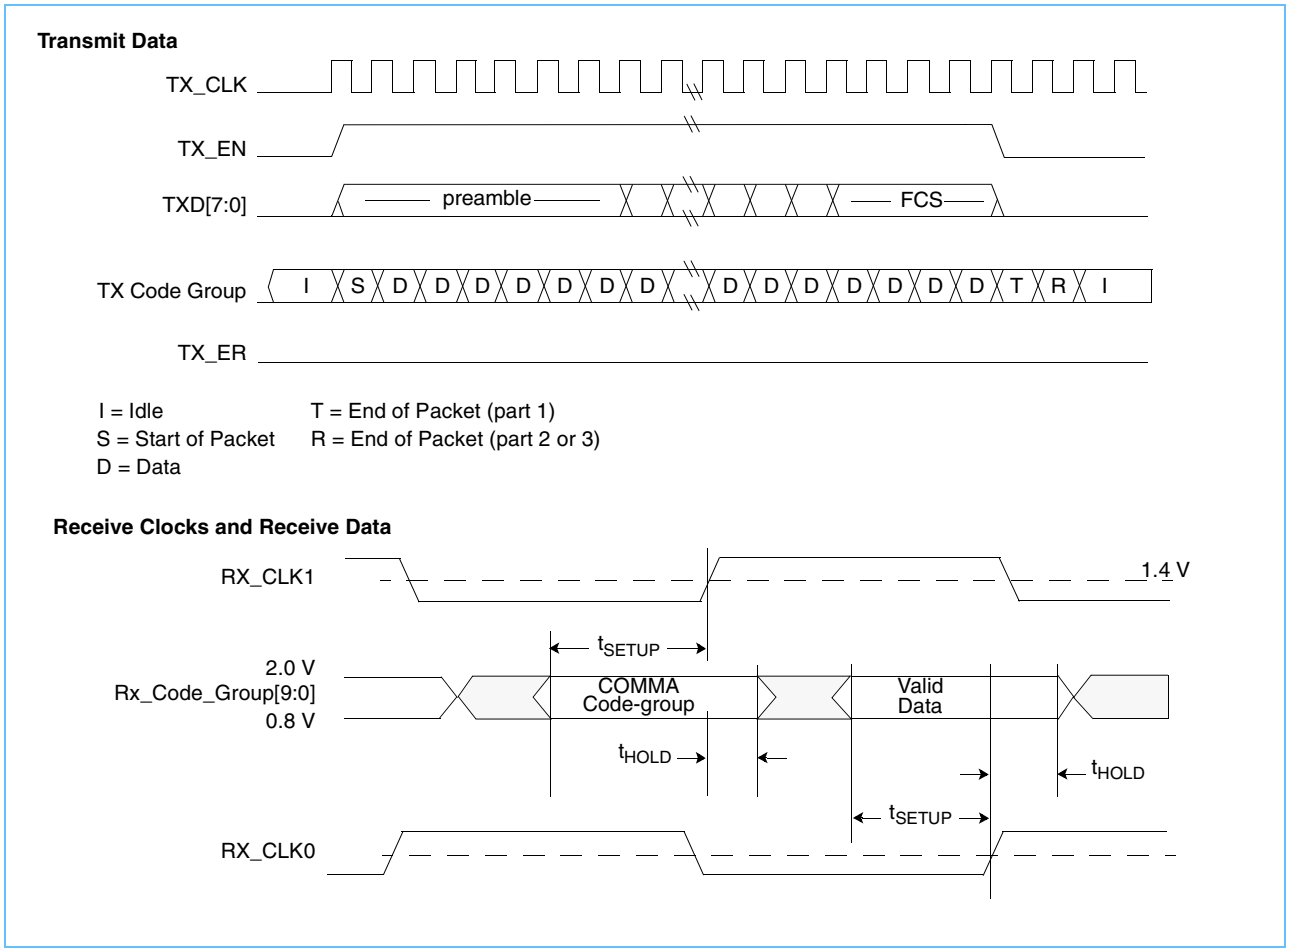

Figure 3-6. GMII POS Mode Timing Diagram

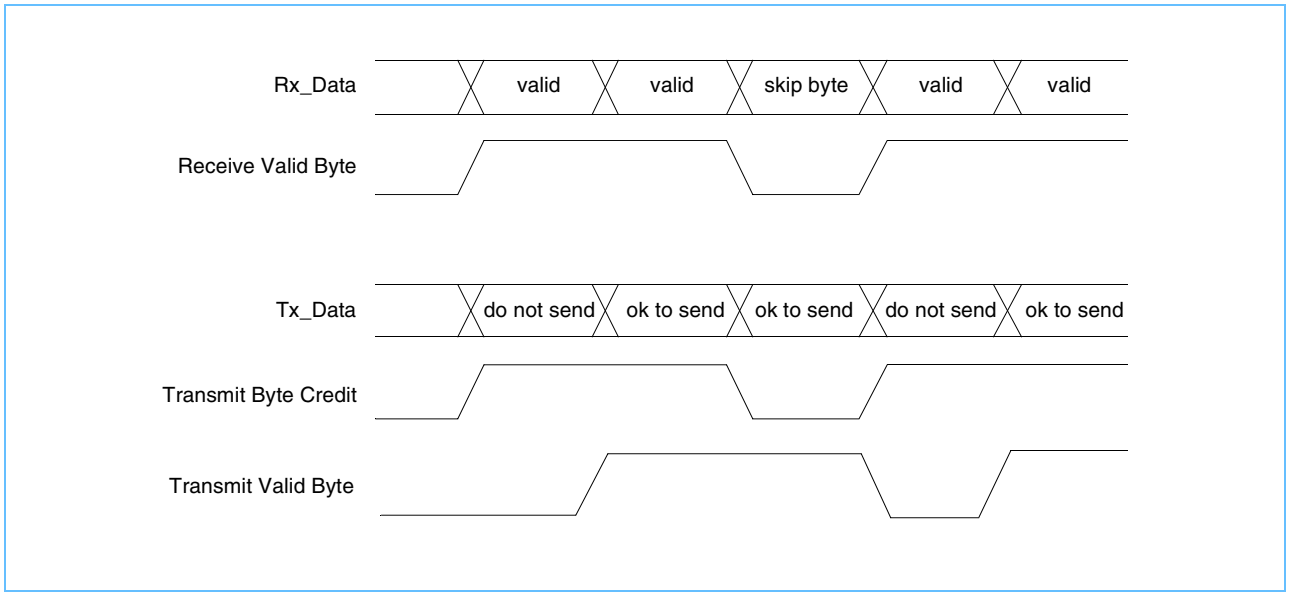

3.1.2 Ethernet Counters

The NP4GS3 provides 36 Ethernet statistics counters per MAC (up to one million software-defined, hardware-assisted counters), enabling support of many standard Management Information Bases (MIBs) at wire speed.

Table 3-1: Ingress Ethernet Counters on page 114 and *Table 3-2: Egress Ethernet Counters* on page 116 show the statistics counters kept in each DMU when it operates in Ethernet mode. These counters are accessible through the Control Access Bus (CAB) interface.

Table 3-1. Ingress Ethernet Counters (Page 1 of 2)

Name / Group	Counter No.	Group	Description	Notes
Short Frames	x'00'	4	Total number of frames received that were less than 64 octets long and were otherwise well-formed (had a good CRC)	1, 2
Fragments	x'01'		Total number of frames received that were less than 64 octets long and had a bad CRC	1, 2
Frames Received (64 octets)	x'02'		Total number of frames (including bad frames) received that were 64 octets in length	1, 2
Frames Received (65 to 127 octets)	x'03'		Total number of frames (including bad frames) received that were between 65 and 127 octets in length inclusive	1, 2
Frames Received (128 to 255 octets)	x'04'		Total number of frames (including bad frames) received that were between 128 and 255 octets in length inclusive	1, 2
Frames Received (256 to 511 octets)	x'05'		Total number of frames (including bad frames) received that were between 256 and 511 octets in length inclusive	1, 2
Frames Received (512 to 1023 octets)	x'06'		Total number of frames (including bad frames) received that were between 512 and 1023 octets in length inclusive	1, 2
Frames Received (1024 to 1518 octets)	x'07'		Total number of frames (including bad frames) received that were between 1024 and 1518 octets in length inclusive	1, 2
Jumbo Frames	x'14'		Total number of frames (including bad frames) received with a length between 1519 and 9018 octets, or between 1519 and 9022 octets if VLAN is asserted. If Jumbo is not asserted the frame is a long frame.	
Long Frames Received	x'08'		Total number of long frames received with a good CRC that were either: 1) Longer than 1518 octets (excluding framing bits, but including CRC octets), and were otherwise well-formed (good CRC), VLAN and Jumbo deasserted 2) VLAN frames that were longer than 1522 octets, with Jumbo deasserted 3) Jumbo frames that were longer than 9018 octets, with VLAN deasserted 4) Jumbo VLAN frames that were longer than 9022 octets	3
Jabber	x'09'		Total number of long frames received with bad CRC that were either: 1) Longer than 1518 octets (excluding framing bits, but including CRC octets), and were not well-formed (Bad CRC), VLAN and Jumbo not asserted 2) VLAN frames that were longer than 1522 octets, with Jumbo deasserted 3) Jumbo frames that were longer than 9018 octets, with VLAN deasserted 4) Jumbo VLAN frames that were longer than 9022 octets	3

1. The states of VLAN or Jumbo have no effect on this count.
2. Excluding framing bits but including CRC octets
3. Reception of frames meeting the criteria for this counter are aborted by the hardware. Abort is indicated in the Ingress Port Control Block and in the Ingress Frame Control Block. If the frame has not been forwarded by the picocode, the picocode must enqueue the frame to the ingress discard queue. If the frame has been forwarded, then the egress hardware will discard the frame. Further reception at the MAC is inhibited until the next frame starts.

Table 3-1. Ingress Ethernet Counters (Page 2 of 2)

Name / Group	Counter No.	Group	Description	Notes
Frames with Bad CRC	x'0A'	3	Total number of frames received that were not long frames, but had bad CRC	2
Unicast Frames Received	x'0B'		Total number of good frames received that were directed to the unicast address (excluding multicast frames, broadcast frames, or long frames)	
Broadcast Frames Received	x'0C'		Total number of good frames received that were directed to the broadcast address (excluding multicast frames or long frames)	
Multicast Frames Received	x'0D'		Total number of good frames received that were directed to the multicast address (excluding broadcast frames, or long frames)	
Total Frames Received	x'0E'	2	Total number of frames (including bad frames, broadcast frames, multicast frames, unicast frames, and long frames) received	
Receive Errors	x'0F'		Total number of frames received in which the PHY detected an error and asserted the Rx_Err signal	
Overruns	x'13'		Total number of frames received when the PMM internal buffer was full and the frame couldn't be stored. Includes frames in the process of being received when the PMM internal buffer becomes full.	
Pause Frames	x'10'		Total number of MAC pause frames received that were well-formed and had a good CRC	
Total Pause Time	x'11'	1	Total amount of time spent in a pause condition as a result of receiving a good pause MAC frame	
Total Octets Received	x'12'	0	Total number of octets of data (including those in bad frames) received on the network	2

1. The states of VLAN or Jumbo have no effect on this count.
2. Excluding framing bits but including CRC octets
3. Reception of frames meeting the criteria for this counter are aborted by the hardware. Abort is indicated in the Ingress Port Control Block and in the Ingress Frame Control Block. If the frame has not been forwarded by the picocode, the picocode must enqueue the frame to the ingress discard queue. If the frame has been forwarded, then the egress hardware will discard the frame. Further reception at the MAC is inhibited until the next frame starts.

Table 3-2. Egress Ethernet Counters (Page 1 of 2)

Name	Counter No.	Group	Description	Cnt
Short Frames	x'00'	4	Total number of frames transmitted with less than 64 octets that had good CRC.	1, 2
Runt Frames (Bad CRC)	x'01'		Total number of frames transmitted with less than 64 octets that had bad CRC.	1, 2
Frames Transmitted (64 octets)	x'02'		Total number of frames (including bad frames) transmitted that were 64 octets in length.	1
Frames Transmitted (65 to 127 octets)	x'03'		Total number of frames (including bad frames) transmitted that were between 65 and 127 octets in length inclusive.	1, 3
Frames Transmitted (128 to 255 octets)	x'04'		Total number of frames (including bad frames) transmitted that were between 128 and 255 octets in length inclusive	1, 3
Frames Transmitted (256 to 511 octets)	x'05'		Total number of frames (including bad frames) transmitted that were between 256 and 511 octets in length inclusive.	1, 3
Frames Transmitted (512 to 1023 octets)	x'06'		Total number of frames (including bad frames) transmitted that were between 512 and 1023 octets in length inclusive.	1, 3
Frames Transmitted (1024 to 1518 octets)	x'07'		Total number of frames (including bad frames) transmitted that were between 1024 and 1518 octets in length inclusive.	1, 3
Jumbo Frames	x'16'		Total number of frames (including bad frames) transmitted with a length between 1519 and 9018 octets, or between 1523 and 9022 if VLAN is asserted. If Jumbo is not asserted, the frame is a long frame.	
Long Frames Transmitted	x'08'		Total number of frames with good CRC transmitted that were either: 1) Longer than 1518 octets (excluding framing bits, but including CRC octets), and were otherwise well-formed (good CRC), VLAN and Jumbo are deasserted 2) VLAN frames that were longer than 1522 octets with Jumbo deasserted 3) Jumbo frames that were longer than 9018 octets with Jumbo deasserted 4) Jumbo VLAN frames that were longer than 9022 octets	
Jabber	x'09'		Total number of frames with bad CRC transmitted that were either: 1) Longer than 1518 octets (excluding framing bits, but including CRC octets), and were otherwise well-formed (good CRC), VLAN and Jumbo are deasserted 2) VLAN frames that were longer than 1522 octets with Jumbo deasserted 3) Jumbo frames that were longer than 9018 octets with Jumbo deasserted 4) Jumbo VLAN frames that were longer than 9022 octets	
Late Collisions	x'0A'		Total number of frames transmitted that experienced a network collision after 64 bytes of the frame had been transmitted.	1

1. The states of VLAN or Jumbo have no effect on this count.
2. Including the frame type byte.
3. Excluding framing bits but including CRC octets.

Table 3-2. Egress Ethernet Counters (Page 2 of 2)

Name	Counter No.	Group	Description	Cnt
Total Collisions	x‘0B’	3	Best estimate of the total number of collisions on this Ethernet segment	1
Single Collisions	x‘0C’		Total number of frames transmitted that experienced one collision before 64 bytes of the frame were transmitted on the network	1
Multiple Collisions	x‘0D’		Total number of frames transmitted that experienced more than one collision before 64 bytes of the frame were transmitted on the network	1
Excessive Deferrals	x‘0E’		Total number of frames whose transmission could not be started before the deferral time out expired. The deferral time out value is 24,416 media bit times.	1
Underruns	x‘0F’		Total number of frames that were not completely transmitted because the data could not be obtained from the Egress EDS fast enough to maintain the media data rate	
Aborted Frames	x‘17’		Total number of frames that had either link status pointer parity errors, or had a header QSB field point beyond EOF, and were aborted by the Egress PMM	
CRC Error	x‘10’	2	Total number of frames transmitted that had a legal length (excluding framing bit, but including CRC octets) of between 64 and 9018 octets, (64 and 9022 for VLAN frames) inclusive, but had a bad CRC	
Excessive Collisions	x‘11’		Total number of frames that experienced more than 16 collisions during transmit attempts. These frames are dropped and not transmitted	
Unicast Frames Transmitted	x‘12’		Total number of good frames transmitted that were directed to the unicast address (not including multicast frames or broadcast frames)	
Broadcast Frames Transmitted	x‘13’		Total number of good frames transmitted that were directed to the broadcast address (not including multicast frames)	
Multicast Frames Transmitted	x‘14’		Total number of good frames transmitted that were directed to the multicast address (not including broadcast frames)	
Total Octets Transmitted	x‘15’	0	Total number of octets of data (including those in bad frames) transmitted on the network	3

1. The states of VLAN or Jumbo have no effect on this count.
2. Including the frame type byte.
3. Excluding framing bits but including CRC octets.

3.1.3 Ethernet Support

Table 3-3 lists the features and standards supported by a DMU in the different Ethernet modes.

Table 3-3. Ethernet Support (Page 1 of 2)

Feature		Ethernet Mode		
		Fast (SMII)	Gigabit (GMII)	Gigabit (TBI)
Fully compatible with IEEE standard	802.3: 1993 (E)	X		
	802.3u / D5.3	X		
	802.3z / D4 standards		X	
	802.3 Clause 36 (TBI) standards			X
Compliant with RFC 1757 Management Registers and Counters (Tx/Rx Counters) Additional receive counters for total number of pause frames and total aggregate pause time Additional transmit counters for number of single collisions and number of multiple collisions		X	X	
Supports the IEEE standards on flow control by honoring received pause frames and inhibiting frame transmission while maintaining pause counter statistics		X	X	
Supports SMII to the PHY Interfaces with up to ten PHYs that support the SMII interface. Each of the ten interfaces can have a bit rate of either 10 Mbps or 100 Mbps.		X		
Capable of handling ten ports of 10 Mbps or 100 Mbps media speeds, any speed mix		X		
Supports half-duplex operations at media speed on all ports		X		
Supports Binary Exponential Back-off (BEB) compliant with the IEEE Std. 802.3: 1993 (E)		X		
Supports full duplex point-to-point operations at media speed		X	X	
Detects VLAN (8100 frame type) Ethernet frames and accounts for them when calculating long frames		X	X	
Supports two Ethernet frame types (programmable) and, based on these, detects received frames with a type field that matches one of those types. A match instructs the Multi-port 10/100 MAC to strip the DA, SA, and Type fields from the received frame and to instruct the higher device functions to queue the frame in a different queue. An example of a special function is to identify Ethernet encapsulated guided frames. A mismatch results in normal frame queueing and normal higher device processing.		X	X	
Programmable cyclic redundancy check (CRC) Insertion on a frame basis With CRC Insertion disabled, MAC transmits frames as is (suitable for switch environments) With CRC Insertion enabled, the MAC calculates and inserts the CRC		X	X	
Includes jumbo frame support. When configured, can transmit and receive up to 9018-byte non-VLAN frames or up to 9022-byte VLAN frames.				
Transfers received data to the upper device layers using a proprietary 16-byte wide interface. In the transmit direction, data from the data mover is sent to the MAC on a single 8-bit bus.		X	X	
Supports the Gigabit Medium Independent Interface (GMII) to the physical TBI layer			X	
Supports the IBM TBI “Valid Byte” signal			X	
Can be combined with the TBI to form a complete TBI solution			X	
Interfaces with any PMA/PMI physical layer using the PMA service interface defined in the IEEE 802.3 standard				X
Synchronizes the data received from the PMA (two phase) clock with the MAC (single phase) clock. Provides a signal to the MAC indicating those clock cycles that contain new data.				X
Checks the received code groups (10 bits) for commas and establishes word synchronization				X

Table 3-3. Ethernet Support (Page 2 of 2)

Feature	Ethernet Mode		
	Fast (SMII)	Gigabit (GMII)	Gigabit (TBI)
Calculates and checks the TBI running disparity			X
Supports auto-negotiation including two next pages			X
Interfaces with the 1000 Mbps Ethernet MAC through the GMII to form a complete TBI solution			X

3.2 POS Overview

A DMU configured in packet over Sonet (POS) mode can support both clear-channel and channelized Optical Carrier (OCs) interfaces. A DMU can support the following types and speeds of POS framers: OC-3c, OC-12, OC-12c, OC-48, and OC-48c.

Each DMU allows connection to OC-3c, OC-12, or OC-12c framers. To provide an OC-48 link, all four DMUs must be attached to a single framer with each DMU providing four OC-3c channels or one OC-12c channel to the framer. To provide an OC-48 clear channel (OC-48c) link, DMU A must be configured to attach to a 32-bit framer and the other three DMUs, although configured for OC-48 mode, are disabled except for their interface pins.

Table 3-4 shows the three DMU configuration modes: OC-3c, OC-12c, and OC-48c. When configured for OC-3c, the DMU assumes that it must poll the four possible attached ports before transferring data. If the DMU is configured for either OC-12c or OC-48c, the DMU does not poll the framer.

Table 3-4. DMU and Framer Configurations

DMU Configuration Mode	Networks Supported via POS Framer
OC-3c (8-bit mode)	4 x OC-3c per DMU or 1 x OC-12c per DMU 1 x OC-48c (all 4 DMUs required)
OC-12c (8-bit mode)	1 x OC-12c per DMU or 1 x OC-48c (all 4 DMUs required)
OC-48c (32-bit mode)	1 x OC-48c (DMU A in 32-bit mode)

Figure 3-7 shows a configuration in which the PMM has OC-3c, OC-12, and OC-12c connections operating simultaneously. Each of the four DMUs has been configured to operate as single port or as four ports. Each of the four DMUs supports an 8-bit data interface in both the ingress and egress directions.

Figure 3-7. OC-3c / OC-12 / OC-12c Configuration

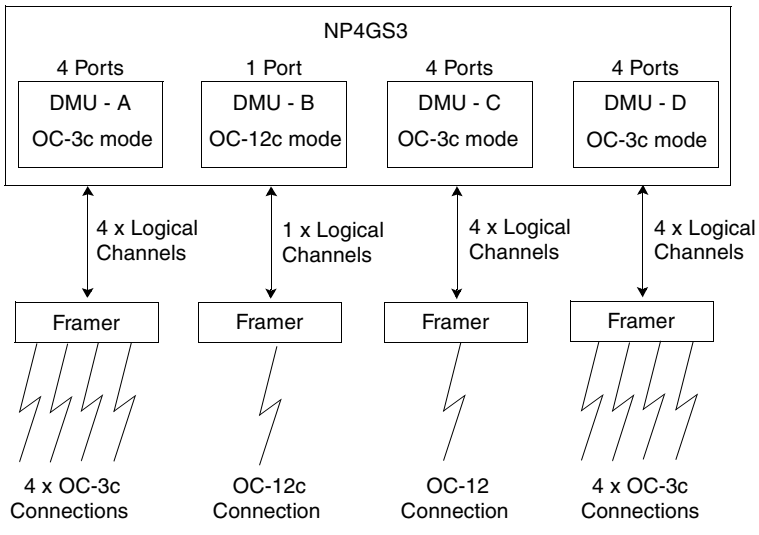

Figure 3-8 shows an OC-48 configuration. Each DMU is configured to operate in a single port mode and to produce either a single OC-12c channel or four OC-3c channels. Each DMU supports an 8-bit data interface in both the ingress and egress directions.

Figure 3-8. OC-48 Configuration

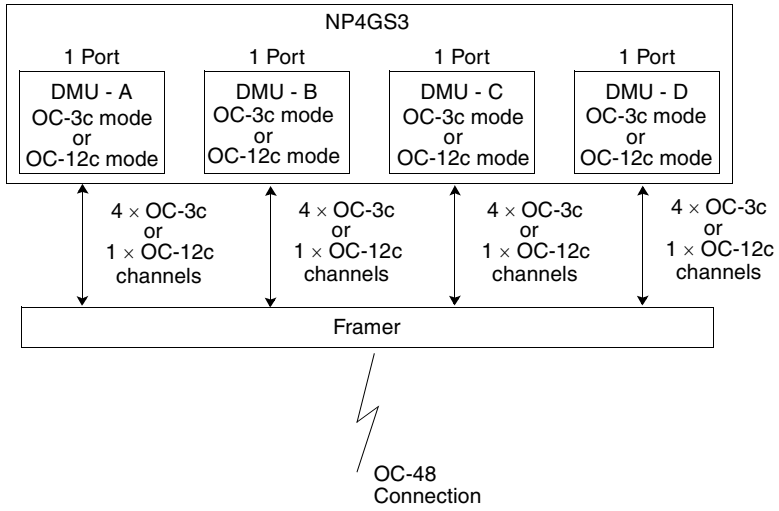

Figure 3-9 shows an OC-48c configuration. DMU A is configured to operate in a single-port 32-bit mode to support OC-48c. DMUs B, C, and D must be configured for OC-48 mode and their data ports routed to DMU A. Except for the I/Os, DMUs B, C, and D are not used in this configuration. The attached framer must also be configured for a 32-bit data interface.

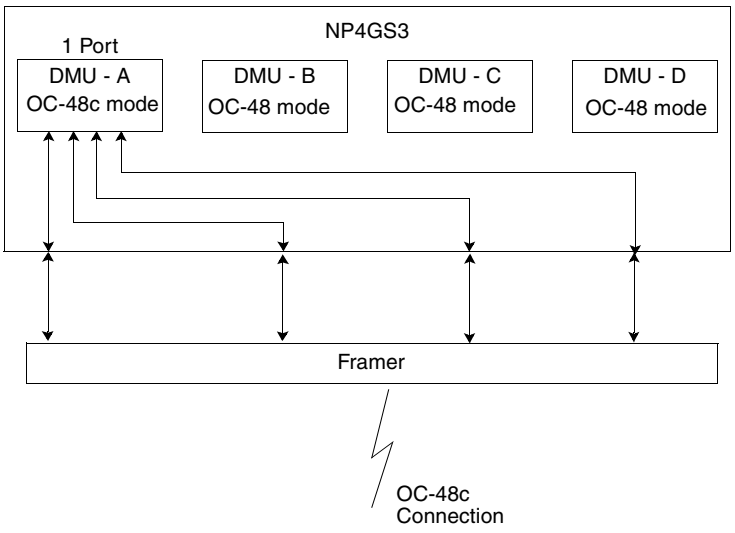
Figure 3-9. OC-48c Configuration

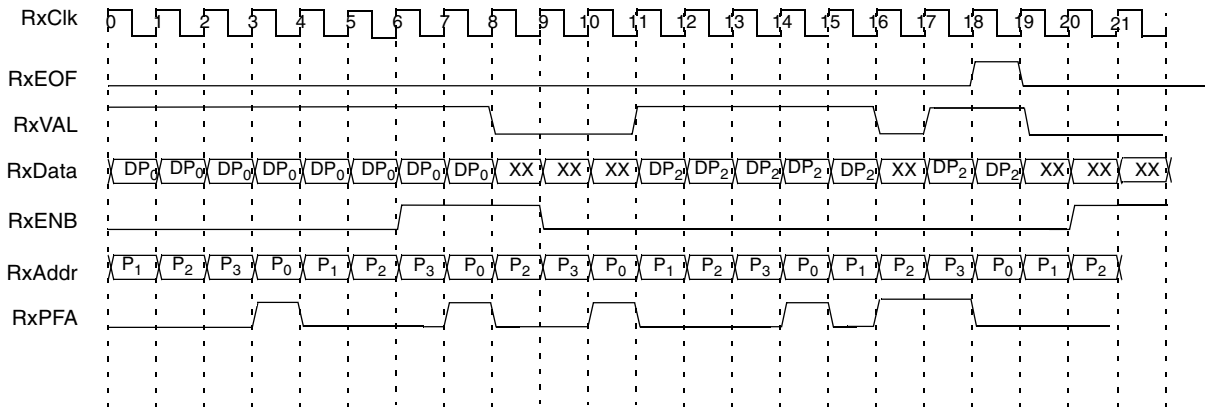


3.2.1 POS Timing Diagrams

The following figures show timing diagrams for the different POS modes:

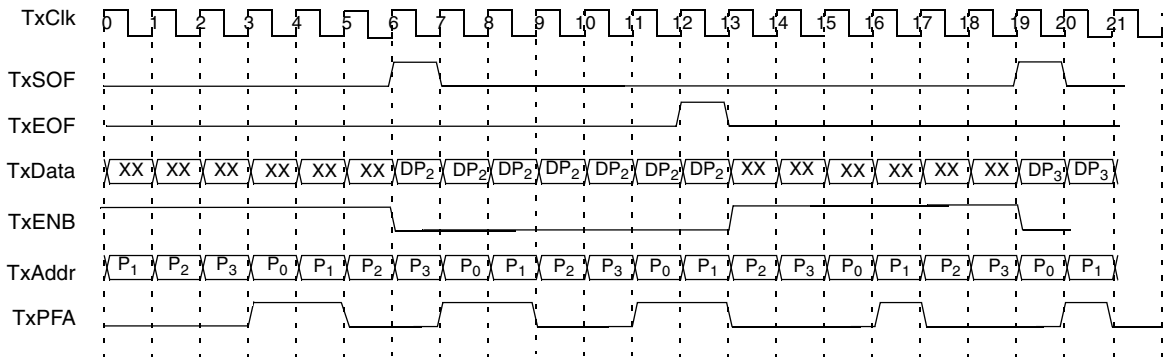
- OC-3c
  - *Figure 3-10: Receive POS8 Interface Timing for 8-bit Data Bus (OC-3c)* on page 122
  - *Figure 3-11: Transmit POS8 Interface Timing for 8-bit Data Bus (OC-3c)* on page 123
- OC-12c
  - *Figure 3-12: Receive POS8 Interface Timing for 8-bit Data Bus (OC-12c)* on page 124
  - *Figure 3-13: Transmit POS8 Interface Timing for 8-bit Data Bus (OC-12c)* on page 125
- OC-48c
  - *Figure 3-14: Receive POS32 Interface Timing for 32-bit Data Bus (OC-48c)* on page 126
  - *Figure 3-15: Transmit POS32 Interface Timing for 32-bit Data Bus (OC-48c)* on page 127

Figure 3-10. Receive POS8 Interface Timing for 8-bit Data Bus (OC-3c)



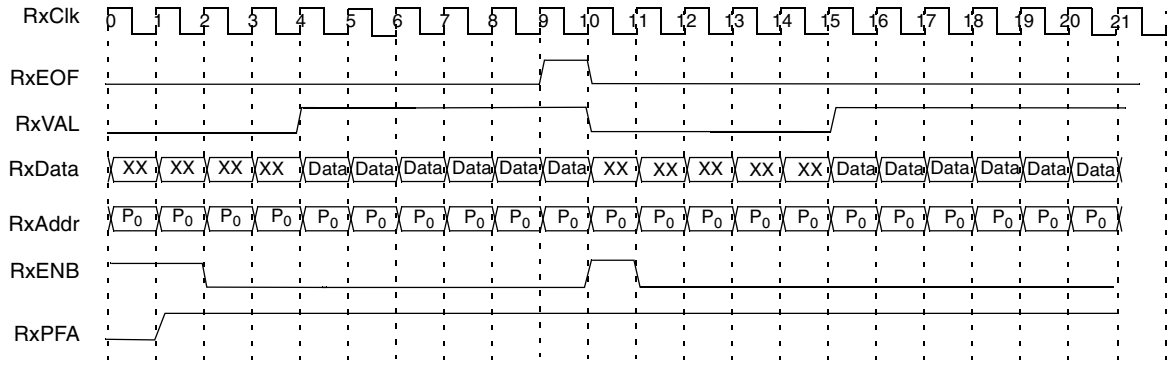
1. Data is being received from port #0 while the DMU is polling.
2. In clock cycle #3 the framer asserts RxPFA indicating data is available. In this example the DMU is configured for two cycles of framer latency (bus_delay = 1), therefore it is port #2 responding with RxPFA(clock cycle #1).
3. In clock cycle #6 the DMU deasserts RxENB (negative active) to indicate it is starting the port selection process.
4. In clock cycle #8 the DMU puts P_2 on RxAddr.
5. In clock cycle #9 the DMU selects port P_2 by asserting RxENB. The port selected is the port whose address is on RxAddr the cycle before RxENB is asserted.
6. In clock cycle #16 the framer deasserts RxVAL (assumed that the framer was not ready to continue data transfer) and restarts data transfer to the DMU during clock cycle #17.
7. In clock cycle #18 the framer asserts RxEOF marking the last transfer for the frame.
8. In clock cycle #19 the framer deasserts both RxEOF and RxVAL completing the frame transfer.
9. In clock cycle #16 and #17 RxPFA is asserted indicating data is available on ports 0 and 1.
10. In clock cycle #20 the DMU starts the selection of the next port.

Figure 3-11. Transmit POS8 Interface Timing for 8-bit Data Bus (OC-3c)



1. In this figure it is assumed that the framer has a 2-cycle delay before responding to the DMU and that the DMU has bus_delay = 1.
2. In clock cycle #3 the framer responds to the Poll by asserting TxPFA, this indicates that the FIFO for ports 2 and 3 have room for data (2 clock cycle delay).
3. In clock cycle #6 the DMU starts transferring a new frame to port 2 by asserting TxSOF, asserting TxENB (negative active), and putting data on TxData.
4. In clock cycle #12 the DMU asserts TxEOF indicating the last transfer of the frame.
5. In clock cycle #13 the DMU deasserts TxENB to indicate that the DMU is in the port selection process.
6. In clock cycle #16 the framer asserts TxPFA indicating it has data for port 3.
7. In clock cycle #19 the DMU asserts TxENB and selects port 3.
8. In clock cycle #19 the DMU asserts TxSOF indicating the start of a new frame for port 3 and places data on TxData.

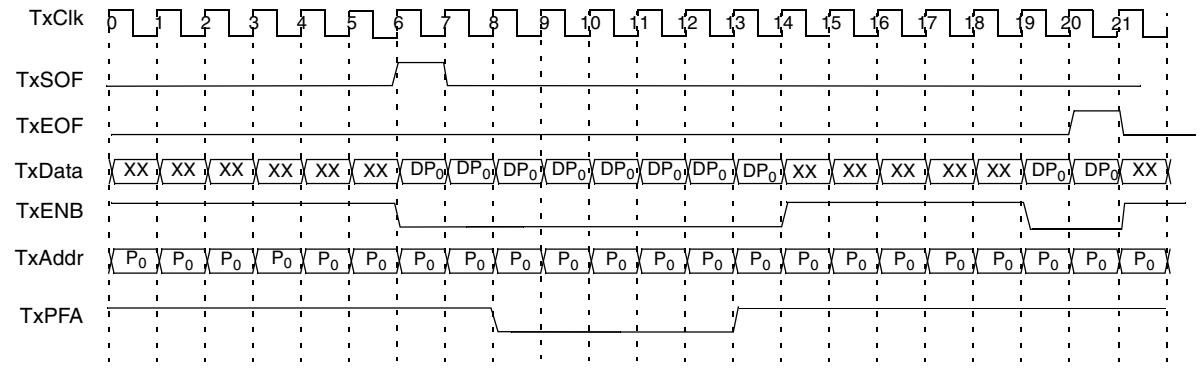
Figure 3-12. Receive POS8 Interface Timing for 8-bit Data Bus (OC-12c)



Note: For OC-12c, RxAddr is not provided by the DMU. RxAddr must be provided by board logic. There is a two cycle delay between the assertion of RxENB and RxVAL, the DMU can accept a one cycle delay.

1. In clock cycle #1 the framer asserts RxPFA indicating it has data to transfer to the DMU (for OC-12c operation the framer can tie RxPFA to a logical 1 and control data transfers with RxVAL).
2. In clock cycle #2 the DMU asserts RxENB (negative active) selecting the port whose address was on RxAddr during clock cycle #1 (for OC-12c operation the DMU must provide RxAddr from the card).
3. In clock cycle #4 the framer asserts RxVAL and starts the data transfer to the DMU. Data transfer continues as long as RxVAL is asserted. The framer must deassert RxVAL at the end of the frame, clock cycle #10, but can deassert and then reassert anytime within the frame.
4. In clock cycle #10 the DMU deasserts RxENB because RxEOF was asserted at clock cycle #9.
5. In clock cycle #11 the DMU asserts RxENB because the framer has RxPFA asserted.
6. In clock cycle #15 the framer starts the transfer of the next frame by asserting RxVAL. The DMU accepts data as early as clock cycle #12 and will wait (no limit) until the framer asserts RxVAL before accepting data.
7. The framer can control data transfer using RxVAL and the DMU can control data transfer using RxENB. As noted above, RxPFA can remain asserted.

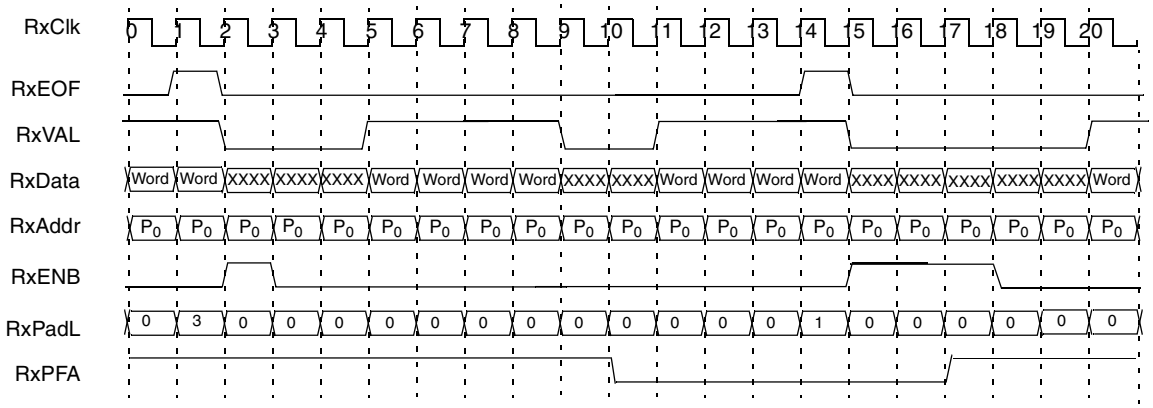
Figure 3-13. Transmit POS8 Interface Timing for 8-bit Data Bus (OC-12c)



Note: For OC-12c, TxAddr is not provided by the DMU. TxAddr must be provided by board logic.

1. In clock cycle #0 the framer has TxPFA asserted indicating it can accept data from the DMU.
2. In clock cycle #6 the DMU selects port 0 by asserting TxENB (negative active). The DMU also asserts TxSOF indicating the beginning of the frame and places data on TxData.
3. In clock cycle #8 the framer indicates it can not accept more data by deasserting TxPFA. The DMU requires 6 clock cycles to stop data transfer, hence data transfer stops after clock cycle #13 by deasserting TxEnb.
4. In clock cycle # 15 the framer asserts TxPFA indicating that it can accept more data.
5. In clock cycle #19 the DMU asserts TxENB indicating data is valid on TxData.
6. In clock cycle #20 the DMU asserts TxEOF indicating the last transfer of the frame.
7. In clock cycle #21 the DMU deasserts TxEOF and TxENB.

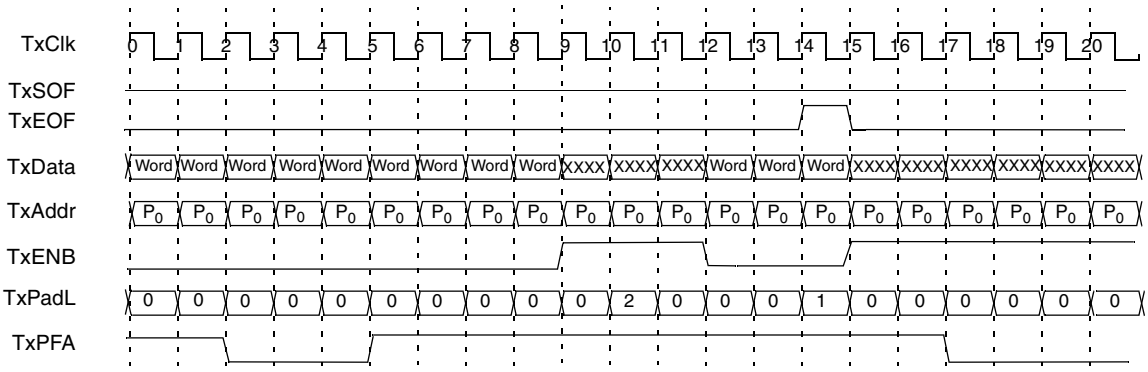
Figure 3-14. Receive POS32 Interface Timing for 32-bit Data Bus (OC-48c)



Note: For OC-48c, RxAddr is not provided by the DMU. RxAddr must be provided by board logic. This figure shows a two clock cycle delay between deassertion of RxEnb and the assertion of RxVal. The DMU can accept a one cycle delay.

1. In clock cycle #0 the DMU is receiving data from the framer.
2. In clock cycle #1 the framer asserts RxEOF indicating the last data transfer of the current frame.
3. In clock cycle #2 the framer deasserts RxEOF and RxVal marking the end of the frame,
4. In clock cycle #2 the DMU deasserts RxENB starting the port selection process.
5. In clock cycle #3 the DMU checks RxPFA (asserted) and asserts RxENB indicating it can accept more data.
6. In clock cycle #5 the data transfer from the framer to the DMU is started. The data transfer continues until clock cycle #15. The framer halts the transfer during cycles 9 and 10 by deaserting RxVal.
7. In clock cycle #14 the framer asserts RxEOF marking the end of the frame.
8. In clock cycle #15 the DMU deasserts RxENB. The DMU asserts RxENB in clock cycle #18 after detecting RxPFA asserted, indicating that the framer has data to transfer. Deassertion of RxENB in clock cycle #18 selects port 0 again and data transfer begins in clock cycle #20.

Figure 3-15. Transmit POS32 Interface Timing for 32-bit Data Bus (OC-48c)



Note: For OC-12c, TxAddr is not provided by the DMU. TxAddr must be provided by board logic.

1. In clock cycle #2 the framer deasserts RxPFA, indicating it can not accept more data from the DMU.
2. In clock cycle #9 the DMU stops the data transfer in response to the deassertion of TxPFA in clock cycle #2.
3. In clock cycle #9 the DMU deasserts TxENB and begins its selection sequence.
4. In clock cycle #5 the framer asserts TxPFA indicating it can again accept data. Seven clock cycles later the DMU will assert TxENB (clock cycle #12) and place the next data word on TxData.
5. In clock cycle #14 the DMU asserts TxEOF to indicate the end of the frame. The DMU also indicates the number of pad bytes in the last data transfer (in this example 3 data bytes were set in the last data transfer).
6. In clock cycle #15 the DMU deasserts TxEOF and deasserts TxENB indicating the end of the frame.
7. In clock cycle #17 the framer deasserts TxPFA indicating that it can not accept more data.

3.2.2 POS Counters

Table 3-5 on page 128 and *Table 3-6* on page 129 provide information about the counters maintained to support POS interfaces.

Many of the counters defined in these tables deal with long frames. A long frame is a packet whose byte count exceeds the value held in the packet over SONET Maximum Frame Size (POS_Max_FS) register (see *Configuration* on page 437). The byte count includes the cyclic redundancy check (CRC) octets.

Reception of packets meeting the criteria for long frames is aborted by the hardware. Abort is indicated in the Ingress Port Control Block and in the Ingress Frame Control Block. If the packet has not been forwarded by the picocode, the picocode must enqueue the packet to the ingress discard queue. If the packet has been forwarded, then the egress hardware will discard the frame. Further reception at the MAC is inhibited until the next packet starts.

Table 3-5. Receive Counter RAM Addresses for Ingress POS MAC (Page 1 of 2)

Port	Name	Counter Number	Description
Port 0	Long Frames Received	x‘00’	Total number of frames received that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘01’	Total number of frames received that had a length of the value contained in the POS Maximum Frame Size Register (POS_Max_FS) or less, but had a bad CRC
	Total Good Frames Received	x‘02’	Total number of frames (excluding frames with bad CRC, and long frames) received
	Receive Errors	x‘03’	Total number of frames received in which the Framer detected an error and asserted the Rx_Err signal
	Total Octets Received (including frames with errors)	x‘10’	Total number of octets of data (including those in bad frames) received on the network
Port 1	Long Frames Received	x‘04’	Total number of frames received that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘05’	Total number of frames received that had a length of the value contained in the POS Maximum frame Size Register (POS_Max_FS) or less, but had a bad CRC
	Total Good Frames Received	x‘06’	Total number of frames (excluding frames with a bad CRC, and long frames) received
	Receive Errors	x‘07’	Total number of frames received in which the Framer detected an error and asserted the Rx_Err signal
	Total Octets Received (including frames with errors)	x‘11’	Total number of octets of data (including those in bad frames) received on the network

Table 3-5. Receive Counter RAM Addresses for Ingress POS MAC (Page 2 of 2)

Port	Name	Counter Number	Description
Port 2	Long Frames Received	x‘08’	Total number of frames received that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘09’	Total number of frames received that had a length of the value contained in the POS Maximum Frame Size Register (POS_Max_FS) or less, but had a bad CRC
	Total Good Frames Received	x‘0A’	Total number of frames (excluding frames with a bad CRC, and long frames) received
	Receive Errors	x‘0B’	Total number of frames received in which the Framer detected an error and asserted the Rxerr signal
	Total Octets Received (including frames with errors)	x‘12’	Total number of octets of data (including those in bad frames) received on the network
Port 3	Long Frames Received	x‘0C’	Total number of frames received that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘0D’	Total number of frames received that had a length of the value contained in the POS Maximum Frame Size Register (POS_Max_FS) or less, but had a bad CRC
	Total Good Frames Received	x‘0E’	Total number of frames (excluding frames with a bad CRC, and long frames) received
	Receive Errors	x‘0F’	Total number of frames received in which the Framer detected an error and asserted the Rx_Err signal
	Total Octets Received (including frames with errors)	x‘13’	Total number of octets of data (including those in bad frames) received on the network

Table 3-6. Transmit Counter RAM Addresses for Egress POS MAC (Page 1 of 2)

Port	Name	Counter Number	Description
Port 0	Long Frames Transmitted	x‘00’	Total number of frames transmitted that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘01’	Total number of frames transmitted that had a length of the value contained in the POS Maximum Frame Register (POS_Max_FS) or less, but had bad CRC
	Total Good Frames Transmitted	x‘02’	Total number of frames (excluding frames with a bad CRC, and long frames) transmitted
	Transmit Underruns	x‘03’	Total number of frames attempted to be transmitted but an under-run occurred in the NP4GS3
	Total Octets Transmitted (including frames with errors)	x‘10’	Total number of octets of data (including those in bad frames) transmitted on the network
	Aborted Frames	x‘14’	Total number of frames that had either link status pointer parity errors, or had a header QSB field point beyond EOF, and were aborted by the Egress PMM

Table 3-6. Transmit Counter RAM Addresses for Egress POS MAC (Page 2 of 2)

Port	Name	Counter Number	Description
Port 1	Long Frames Transmitted	x‘04’	Total number of frames transmitted that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘05’	Total number of frames transmitted that had a length of the value contained in the POS Maximum Frame Register (POS_Max_FS) or less, but had bad CRC
	Total Good Frames Transmitted	x‘06’	Total number of frames (excluding frames with a bad CRC, and long frames) transmitted
	Transmit Underruns	x‘07’	Total number of frames attempted to be transmitted, but an under-run occurred in the NP4GS3
	Total Octets Transmitted (including frames with errors)	x‘11’	Total number of octets of data (including those in bad frames) transmitted on the network
	Aborted Frames	x‘15’	Total number of frames that had either link status pointer parity errors, or had a header QSB field point beyond EOF, and were aborted by the Egress PMM
Port 2	Long Frames Transmitted	x‘08’	Total number of frames transmitted that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘09’	Total number of frames transmitted that had a length of the value contained in the POS Maximum Frame Register (POS_Max_FS) or less, but had bad CRC
	Total Good Frames Transmitted	x‘0A’	Total number of frames (excluding frames with a bad CRC, and long frames) transmitted
	Transmit Underruns	x‘0B’	Total number of frames attempted to be transmitted, but an under-run occurred in the NP4GS3
	Total Octets Transmitted (including frames with errors)	x‘12’	Total number of octets of data (including those in bad frames) transmitted on the network
	Aborted Frames	x‘16’	Total number of frames that had either link status pointer parity errors, or had a header QSB field point beyond EOF, and were aborted by the Egress PMM
Port 3	Long Frames Transmitted	x‘0C’	Total number of frames transmitted that were longer than the value contained in the POS Maximum Frame Size Register (POS_Max_FS) including CRC octets
	Frames with Bad CRC	x‘0D’	Total number of frames transmitted that had a length of the value contained in the POS Maximum Frame Register (POS_Max_FS) or less, but had bad CRC
	Total Good Frames Transmitted	x‘0E’	Total number of frames (excluding frames with a bad CRC, and long frames) transmitted
	Transmit Underruns	x‘0F’	Total number of frames attempted to be transmitted but an under-run occurred in the NP4GS3
	Total Octets Transmitted (including frames with errors)	x‘13’	Total number of octets of data (including those in bad frames) transmitted on the network
	Aborted Frames	x‘17’	Total number of frames that had either link status pointer parity errors, or had a header QSB field point beyond EOF, and were aborted by the Egress PMM

3.2.3 POS Support

Table 3-7 lists the features and standards supported by a DMU in the different POS modes.

Table 3-7. POS Support

Feature	POS Mode	
	OC-3c & OC-12c (8-Bit)	OC-48c (32-Bit)
Supports quad-port OC-3c connections, quad-port OC-12 connections, or single-port OC-12c connections	X	
Supports a single port OC-48c connection		X
Compatible with Flexbus™ 3 - Quad- 8 bit bus operational mode	X	
Compatible with Flexbus™ 3 - Single - 32 bit bus operational mode		X
Programmable CRC Insertion on a frame basis. With CRC Insertion disabled, the MAC transmits frames as is (suitable for switch environments). With CRC Insertion enabled, the MAC calculates and inserts the CRC.	X	X
The minimum frame length the NP4GS3 can handle at a sustainable rate is 18 bytes. Smaller frames can be handled, but will consume the bandwidth of an 18-byte frame. An indirect back-pressure between the processor and the framer prevents frames from being lost, unless many small frames are received back-to-back.	X	X
Provides the following nine Tx Counters for testing and debugging purposes: number of bytes transmitted / received number of frames transmitted / received number of long frames transmitted / received number of frames with bad CRC transmitted / received number of receive errors	X	X

4. Ingress Enqueuer / Dequeuer / Scheduler

4.1 Overview

The Ingress Enqueuer / Dequeuer / Scheduler (Ingress EDS) interfaces with the Physical MAC Multiplexer (PMM), the Embedded Processor Complex (EPC), and the Ingress Switch Interface (Ingress SWI). Frames that have been received on the Data Mover Unit (DMU) interface are passed through the PMM to the Ingress EDS. The Ingress EDS collects the frame data in its internal Data Store; when it has received sufficient data, the Ingress EDS enqueues the frame to the EPC for processing. The Ingress EDS does not need to receive the entire frame before it enqueues the data (that is, it can operate in cut-through mode).

Once the EPC processes the frame, it provides forwarding and quality of service (QoS) information to the Ingress EDS. The Ingress EDS then invokes hardware configured flow control mechanisms and then either discards the frame or places it into a queue to await transmission.

The Ingress EDS schedules all frames that cross the Ingress SWI. After it selects a frame, the Ingress EDS passes the frame data to the Ingress SWI, which segments the frame into data cells and sends them on to the data-aligned synchronous link (DASL) interface (which, in turn, passes the data to the switch fabric).

4.2 Operation

Figure 4-1. Logical Organization of Ingress EDS Data Flow Management

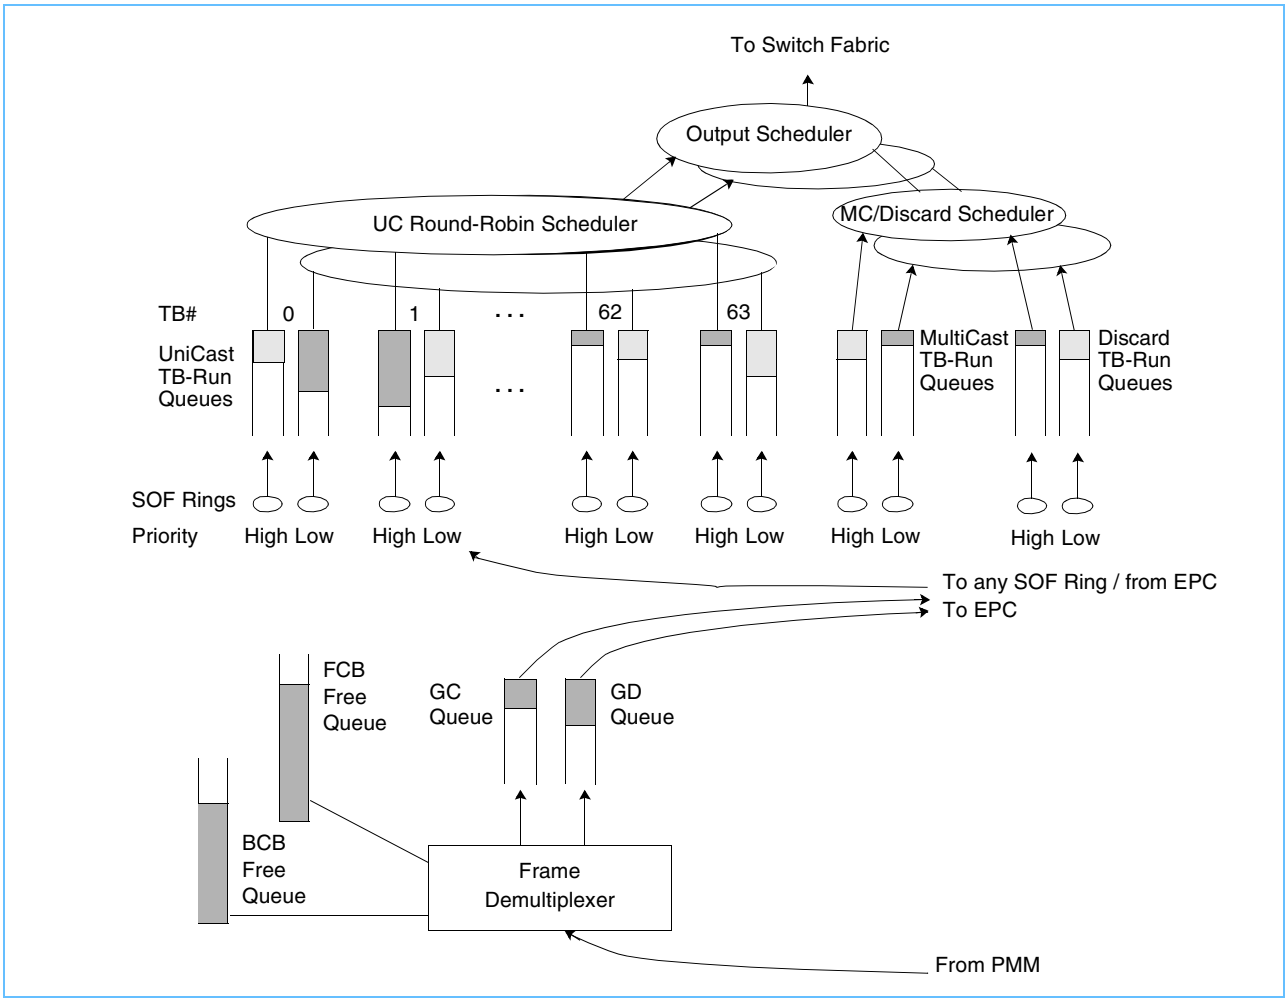


Figure 4-1 illustrates the operations of the Ingress EDS discussed in this section.

The Frame Demultiplexer (FD) receives incoming frames from the PMM. An FCB is allocated on-the-fly from the FCB Free queue as each new frame starts. The FD writes each frame as a list of chained data buffers into its internal ingress Data Store. The buffer addresses are dequeued on-the-fly from the BCB Free queue, which is the linked list of all currently available data buffer addresses.

The EPC can process the frames under one of the following conditions:

- Cut-through mode is disabled and the frame has been completely received.
- Cut-through mode is enabled and sufficient data has been received.
  The quantity of sufficient data in cut-through mode is programmable in increments of 64 bytes. The first 64 bytes of a frame, in most cases, contain the information to be used in Layer 2, Layer 3, and Layer 4 forwarding.

When a frame is ready for processing by the EPC, the Ingress EDS enqueues its FCB to an input queue: either the GC queue (for control frames) or the GD queue (for data frames).

The EPC is responsible for recognizing that a frame is ready to be processed, dequeueing and processing it, and giving it back to the Ingress EDS (by enqueueing to a TDMU queue) for forwarding to the Ingress SWI.

The EPC returns each frame in an ingress enqueue operation to a specific target Data Mover Unit (TDMU) queue (as determined by the routing table lookup). At this point in the flow, the Ingress EDS flow control logic determines if the frame should be enqueued into the Ingress Scheduler (that is, added to the TDMU queue) or if it should be discarded. See *Section 4.3 Ingress Flow Control* on page 138 for details.

TDMU queues are linked in start-of-frame (SOF) rings. An SOF ring can hold up to four TDMU queues. To maintain optimal ring structure, only non-empty TDMU queue are included in an SOF ring.

Each SOF ring is associated with a particular TB-Run queue, creating an SOF ring / TB-Run queue set that provides a fair initiation of frame transmission to all DMUs of a target Network Processor. Fairness is achieved by a round-robin mechanism that successively selects each TDMU queue in the SOF Ring. When a TDMU queue is selected, the frame currently at its head is dequeued from the TDMU queue and enqueued in a TB-Run queue (the actual entry-point of data movement to the Ingress SWI) once sufficient data for forwarding has been received.

For each target blade (TB) (the frame's destination across the switch), there are two SOF ring / TB-Run queue sets: one for Unicast High Priority Traffic and one for Unicast Low Priority Traffic. Four other sets are reserved for Multicast High and Low Priority Traffic, and for High and Low Priority Discard Traffic. All six sets are scheduled for service at each switch cell time.

For each priority plane, round-robin scheduling is performed between the 64 unicast TB-Run queues and the multicast and discard traffic. A second level of scheduling alternates between the selected unicast candidate and the candidate from the multicast and discard TB-Run queues.

These schedulers are controlled by the status (empty or non-empty) of each TB-Run queue, and by the flow control indication received from the Switch Interface (SWI). Congestion information from the SWI is comprised of three "grants":

Master Grant (Master_Grant_A/B)	Loss of Master Grant of a priority eliminates all queues of the indicated priority from the round-robin selection, with the exception of the discard queues.
Multicast Grant (MC_Grant_A/B)	Loss of Multicast Grant of a priority eliminates all multicast queues of the indicated priority from the round-robin selection.
Output Queue Grant (OQG)	Loss of OQG for a target blade and priority eliminates that target blade and priority queue from the round-robin selection (see *Section 5.4.2 Output Queue Grant Reporting* on page 153).

Absolute priority is enforced: the Low Priority candidate is used only if there is no High Priority candidate present at the time.

The cut-through function is supported by queueing partial frames that contain enough data to fill a switch cell. If, after scheduling to the switch, enough data remains in the frame to fill another switch cell, then the frame is kept in the TB-Run queue. If all the frame data has not been received from the PMM, but there is insufficient data in the data store to fill the next switch cell, the FCB is removed from the TB-Run queue and left "floating" (not part of any queue). When the Frame Demultiplexer detects that there is enough data to fill a switch cell, or the last byte of the frame is received, it re-enqueues the frame in its TB-Run queue. If all the frame data has been received, the FCB stays in the TB-Run queue until all the data has been moved to the SWI. At that point, the FCB is sent to the FCB free queue.

As can be seen from the above description, the I-EDS may have multiple frames "in flight". The number of frames that may be simultaniously in a state of transmission is controlled by the configuration of the TB Mode Register (TB_Mode) (see section *13.3 TB Mode Register (TB_Mode)* on page 446). This value controls the number of correlators available (see *Table 5-1: Cell Header Fields* on page 145). The I-EDS maintains correlator free pools for unicast and multicast frames and for each priority (total of four free pools).

Note: For packed frames, two correlators are required, one for the frame completing and one for the frame that is starting (see *Table 5-1: Cell Header Fields* on page 145 and *Table 5-2: Frame Header Fields* on page 148).

4.2.1 Operational Details

This section provides more details about some of the operations described in *Section 4.2*.

Figure 4-2 details the structure of the start-of-frame (SOF) rings acting as multiple-port entry points to the target Data Mover Unit (TDMU) queues. An SOF ring is a circular linked list of TDMU queues dynamically inserted into and removed from the ring. Note that the multicast and discard SOF rings contain only a single TDMU queue.

Figure 4-2. SOF Ring Structure

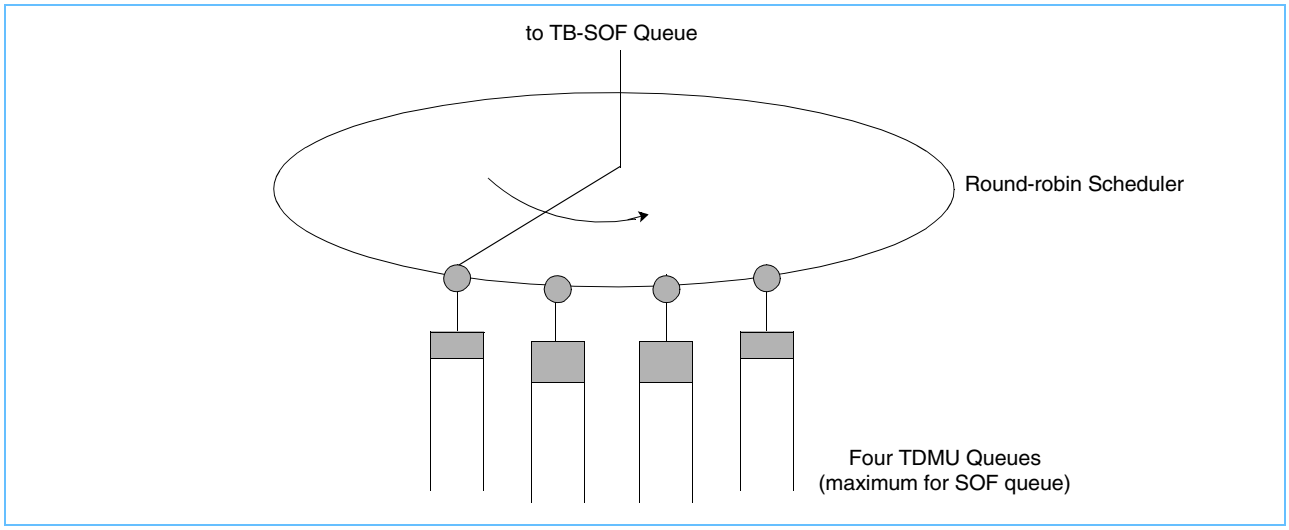

Figure 4-3: Ingress EDS Logical Structure on page 137 illustrates the various logical structures of the EDS that are discussed in the rest of this section.

A frame (or packet) is stored in the internal Ingress Data Store in the form of a linked list of data buffers. Each data buffer is a 64-byte area of the Ingress Data Store. The Ingress Data Store has 2048 data buffers available, each with a unique identifier value (0 through 2047).

Data buffers are chained by Next Buffer Control Block Address (NBA) pointers located in buffer control blocks (BCBs). One BCB is associated with each data buffer and shares the same identifier value (there are 2048 BCBs). BCBs are physically located in an independent imbedded memory.

Each frame is represented by a frame control block (FCB) that identifies the new frame by data location (the address of the first buffer in the Data Store) and control information (the Source Port from which this frame originated). 2048 FCBs are available in an independent embedded memory. Each FCB contains parameters associated with the frame, such as the two pointers shown in *Figure 4-3*:

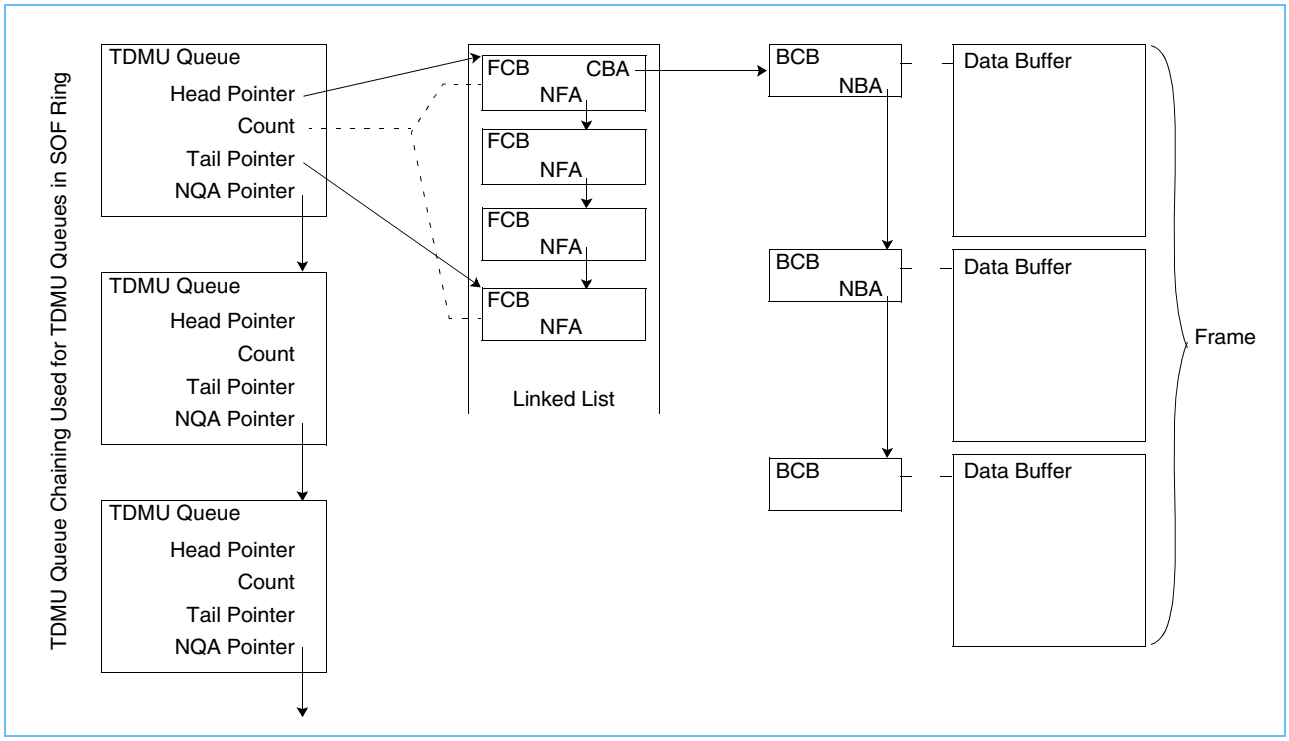
- The control block address (CBA) points to the first data buffer of a frame (for frames whose transmission to the switch has not started), or the data buffer ready to be transmitted (for frames whose transmission to the Ingress SWI has already started).
- The next FCB address (NFA) points to the FCB of the next frame in the queue.

The FCB also maintains information about the amount of one frame's data currently in the Ingress Data Store. As the data is moved out of the Data Store across the SWI, the FCB accounting information reflects the reduction in data present in the Data Store. At the same time, more of the frame's data may still be arriving from the PMM, and the accounting information in the FCB will reflect the increase of data in the data store.

Frames are chained in queues which consist of FIFO-linked lists of FCBs and the queue control blocks TDMU queues. A TDMU queue contains the information necessary to manage the linked list of FCBs, particularly:

- Head pointer: points to the first FCB in the queue
- Tail pointer: points to the last FCB in the queue
- Count: indicates how many FCBs are present in the queue
- Next QCB Address (NQA) pointer: points to the next TDMU queue. This pointer enables the chaining of TDMU queues and is the mechanism for creating the SOF ring and TDMU queues.

Figure 4-3. Ingress EDS Logical Structure



4.3 Ingress Flow Control

Flow control (whether to forward or discard frames) in the network processor is provided by hardware assist mechanisms and by picocode that implements a selected flow control algorithm. In general, flow control algorithms require information about the congestion state of the data flow, the rate at which packets arrive, the current status of the data store, the current status of target blades, and so on. A transmit probability for various flows is an output of these algorithms.

The network processor implements flow control in two ways:

- Flow control is invoked when the frame is enqueued to a start-of-frame (SOF) queue. The hardware assist mechanisms use the transmit probability along with tail drop congestion indicators to determine if a forwarding or discard action should be taken during frame enqueue operation. The flow control hardware uses the picocode's entries in the ingress transmit probability memory to determine what flow control actions are required.
- Flow control is invoked when frame data enters the network processor. When the Ingress DS is sufficiently congested, these flow control actions discard either all frames, all data frames, or new data frames. The thresholds that control the invocation of these actions are BCB_FQ Threshold for Guided Traffic, BCB_FQ_Threshold_0, and BCB_FQ_Threshold_1 (see *Table 4-1: Flow Control Hardware Facilities* on page 139 for more information).

4.3.1 Flow Control Hardware Facilities

The hardware facilities listed in *Table 4-1* are provided for the picocode's use when implementing a flow control algorithm. The picocode uses the information from these facilities to create entries in the ingress transmit probability memory. The flow control hardware uses these entries when determining what flow control actions are required.

Table 4-1. Flow Control Hardware Facilities

Name	Definition	Access
BCB Free Queue (BCB_FQ) Control Block Register	Provides an instantaneous count of the number of free buffers available in the Ingress Data Store.	CAB
BCB_FQ Threshold for Guided Traffic	Threshold for BCB_FQ. When BCB_FQ < BCB_FQ_GT_Th, no further buffers are allocated for incoming data.	CAB
BCB_FQ_Threshold_0	Threshold for BCB_FQ. When BCB_FQ < BCB_FQ_Threshold_0, no further buffers are allocated for incoming user traffic. Guided traffic can still allocate new buffers. When this threshold is violated, an interrupt (Class 0, bit 0) is signaled.	CAB
BCB_FQ_Threshold_1	Threshold for BCB_FQ. When BCB_FQ < BCB_FQ_Threshold_1, no further buffers are allocated for new incoming user traffic. Guided traffic and packets already started can still allocate new buffers. When this threshold is violated, an interrupt (Class 0, bit 1) is signaled.	CAB
BCB_FQ_Threshold_2	Threshold for BCB_FQ. When BCB_FQ < BCB_FQ_Threshold_2, an interrupt (Class 0, bit 2) is signaled.	CAB
Flow Control Ingress Free Queue Threshold (FQ_P0_Th)	Threshold for BCB_FQ used when determining flow control actions against Priority 0 traffic. When BCB_FQ < FQ_P0_Th, the flow control hardware discards the frame.	CAB
Flow Control Ingress Free Queue Threshold (FQ_P1_Th)	Threshold for BCB_FQ used when determining flow control actions against Priority 1 traffic. When BCB_FQ < FQ_P1_Th, the flow control hardware discards the frame.	CAB
BCB FQ Arrival Count	Arrival rate of data into the Ingress Data Store. This counter increments each time there is a dequeue from the BCB free queue. When read by picocode via the CAB, this counter is set to 0 (Read with Reset).	CAB
Ingress Free Queue Count Exponentially Weighted Moving Average	Calculated EWMA of the BCB FQ (BCB_FQ_EWMA).	CAB
Flow Control Ingress Free Queue Threshold (FQ_SBFQ_Th)	Threshold for BCB_FQ. When BCB_FQ < FQ_SBFQ_TH, the I_FreeQ_Th is set to 1. This may be used by external devices assisting in flow control.	CAB
LocalTB_MC_Status_0	Threshold status of the priority 0 TDMU queues and the multicast queue. The count and the threshold are compared four times per target blade (once per DMU). The results are combined into a single result on the target blade, and the corresponding bit is set in LocalTB_MC_Status_0. If TDMU_QCB.QCnt > TDMU_QCB.Th, the bit is set to 1; if not, it is set to 0.	Hardware only
TDMU Queue Control Block (DMU_QCB)	Threshold for number of frames enqueued to the TDMU. These values are used to compare against the queue count when setting LocalTB_MC_Status_0 bits.	CAB
Remote TB Status 0	This 64-bit register contains the congestion status of all remote target blades' Egress Data Stores. The congestion status of each remote target blade is the result of a comparison between the configured threshold and the EWMA of the offered rate of priority 0 traffic (See *Table 6-1: Flow Control Hardware Facilities* on page 168). This information is collected via the res_data I/O.	Hardware only
Remote TB Status 1	This 64-bit register contains the congestion status of all remote target blades' Egress Data Stores. The congestion status of each remote target blade is the result of a comparison between the configured threshold and the EWMA of the offered rate of priority 1 traffic (See *Table 6-1: Flow Control Hardware Facilities* on page 168). This information is collected via the res_data I/O.	Hardware only

4.3.2 Hardware Function

4.3.2.1 Exponentially Weighted Moving Average (EWMA)

The hardware generates EWMA values for the BCB_FQ count, thus removing the burden of this calculation from the picocode. In general, EWMA for a counter X is calculated as follows:

EWMA_X = (1 - K) * EWMA_X + K * X

This calculation occurs for a configured sample period and K $\in$ {1, 1/2, 1/4, 1/8}.

4.3.2.2 Flow Control Hardware Actions

When the picocode enqueues a packet to be transmitted to a target blade, the flow control hardware examines the state of the FQ_P0_Th and FQ_P1_Th threshold statuses and the priority of the enqueued packet to determine what flow control action is required.

- If the FCInfo field of the FCBPage of the enqueued packet is set to x'F', flow control is disabled and the packet is forwarded.
- For priority 0 packets, if FQ_P0_TH or LocalTB_MC_Status_0 or Remote TB Status 0 is exceeded, the packet is discarded (tail drop discard). The picocode must set up a counter block to count these discards.
- For priority 1 packets, if FQ_P1_TH is exceeded, the packet is discarded (tail drop discard). Otherwise, the transmit probability table is accessed and the value obtained is compared against a random number ($\in$ {0 ...1}) generated by the hardware. When the transmit probability is less than the random number, the packet is discarded.

  The index into the transmit probability table is QQQTCC, where:

QQQ	Quality of Service (QoS) Class taken from the DSCP (Ingress FCBpage TOS field bits 7:5)
T	Remote target blade (TB) Status; one bit corresponding to the target blade (zero when the frame is multicast.)
CC	Diffserv code point (DSCP) assigned color (Ingress FCBpage FCInfo field bits 1:0)

5. Switch Interface

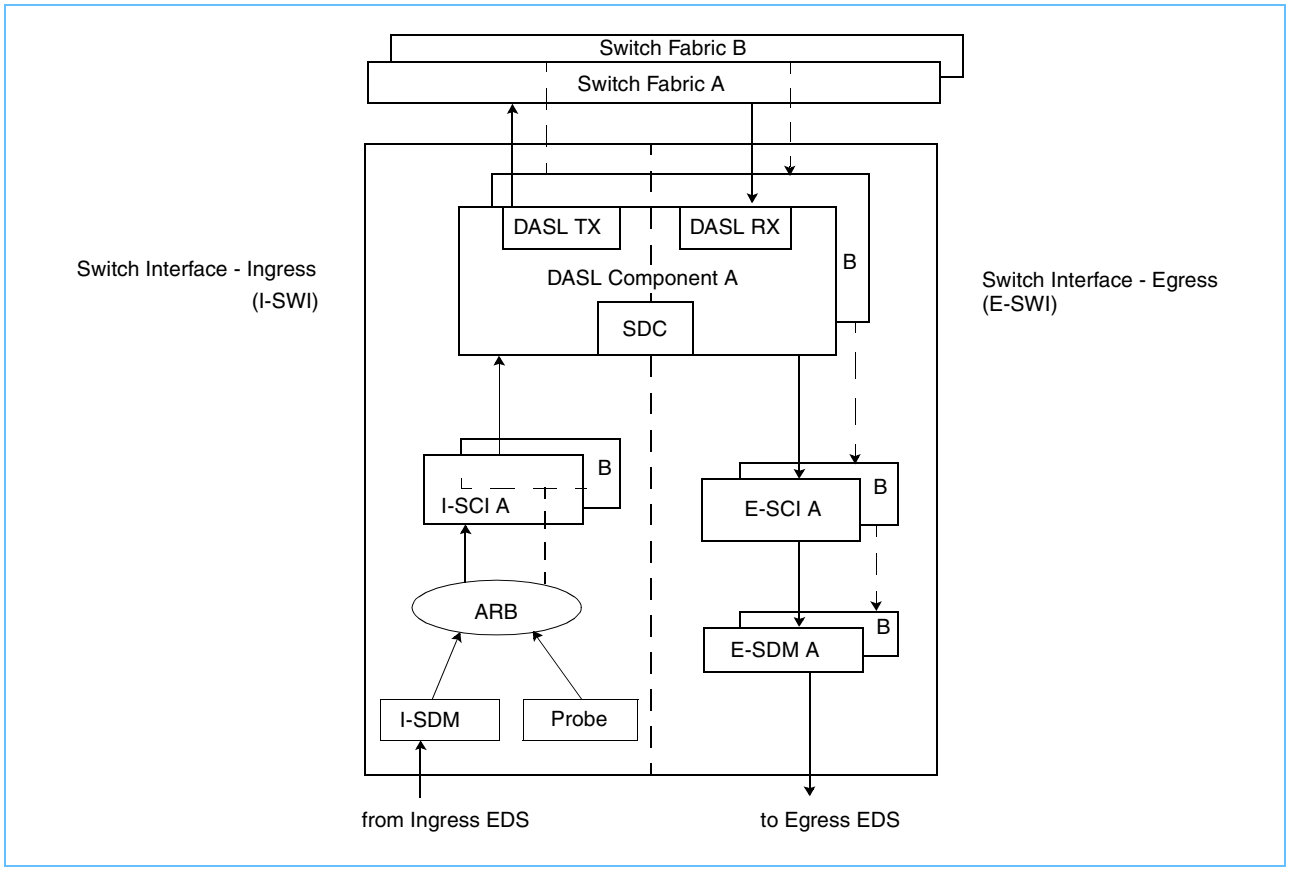
The Switch Interface (SWI) supports two high-speed data-aligned synchronous link (DASL) interfaces to attach the NP4GS3 to itself, to other network processors, or to an external switch fabric. (For purposes of discussion, this text assumes that the connection is to a switch fabric.) Each DASL link supports up to 3.25 to 4 Gbps throughput. The DASL links can be used in parallel (for example, to interconnect two network processors as dual network processors) or with one as the primary switch interface and the other as an alternate switch interface (for increased system availability). The DASL interfaces enable up to 64 network processors to be interconnected using an external switch fabric.

The SWI supports the following:

- Two DASL switch interfaces
- Simultaneous transfer of cells on the SWI in both ingress and egress directions
- Building a Cell Header and Frame Header for each frame
- Segmenting a frame into 64-byte switch cells
- Cell packing

The SWI's ingress side sends data to the switch fabric and its egress side receives data from the switch fabric. The DASL bus consists of four paralleled links: one master and three slaves. The NP4GS3 supports two DASL channels (A and B). An arbiter sits between the Ingress Switch Data Mover (I-SDM) and Ingress Switch Cell Interfaces SCI_A-1 and SCI_B-1. The arbiter directs the data traffic from the I-SDM and Probe to the appropriate I-SCI, based on switch_BnA device input and the settings in the DASL Configuration register (see *13.29.1 DASL Configuration Register (DASL_Config)* on page 502). *Figure 5-1* on page 142 shows the main functional blocks of the SWI.

Figure 5-1. Switch Interface Functional Blocks



The main units, described in following sections, are:

- I-SDM: Ingress Switch Data Mover
- I-SCI: Ingress Switch Cell Interface
- DASL: Data-Aligned Synchronous Links
- E-SCI: Egress Switch Cell Interface
- E-SDM: Egress Switch Data Mover

5.1 Ingress Switch Data Mover

The Ingress Switch Data Mover (I-SDM) is the logical interface between the Ingress Enqueuer / Dequeuer / Scheduler's (EDS) frame data flow and the switch fabric's cell data flow. The I-SDM segments the frames into cells and passes the cells to the I-SCI. The I-SDM also provides the following frame alteration functions:

- VLAN insert or overlay. The four bytes comprising the VLAN type field (x'8100') and the Tag control field are placed after the 12th byte of the frame.
- n-byte delete. Bytes may be deleted from the incoming frame prior to being sent to the SWI.

The Ingress EDS controls the I-SDM data input by requesting the I-SDM to transmit data to the switch. To do this, the Ingress EDS gives the I-SDM the control information necessary to transmit one segment (either 48 or 58 bytes) of data from the selected frame. The control information consists of a buffer control block (BCB) address, frame control block (FCB) record contents, and the BCB address of the next frame going to the same switch destination (used for packing). With this information, the I-SDM builds a switch cell under a quadword-aligned format compatible with the data structure in the Egress Data Store. The logical switch cell structure contains three fields: Cell Header, Frame Header, and Data.

The first cell of a frame contains a cell header, a frame header, and 48 bytes of frame data. Following cells of a frame contain a cell header followed by 58 bytes of frame data. The final cell of a frame contains the cell header, remaining bytes of frame data, and any necessary bytes to pad out the remainder of the cell.

To increase the effective bandwidth to the switch, the network processor implements frame packing where the remaining bytes of a final cell contain the frame header and beginning bytes of the next frame. Packing is used with unicast frames when the target blade and priority of the next frame are the same as the target blade and priority of the preceding frame. In this case, the packed cell contains a 6-byte cell header, the remaining data bytes of the first frame, a 10-byte frame header of the second frame, and some data bytes of the second frame. Packing of frames occurs on 16-byte boundaries within a cell.

To complete the logical cell, the I-SDM assembles control information from the FCB that was sent from the Ingress EDS, and utilizes data bytes read from the ingress data store buffers. Logical cells are passed to the I-SCI using a grant handshake.

5.1.1 Cell Header

A cell header is a 6-byte field holding control information for the cell. The first three bytes are used by the switch fabric for routing and flow control. The last three bytes are used by the target network processor.

A cell header is sent with each cell across the attached switch fabric. *Figure 5-2* illustrates the format of a cell header; *Table 5-1* provides the field definitions.

Figure 5-2. Cell Header Format

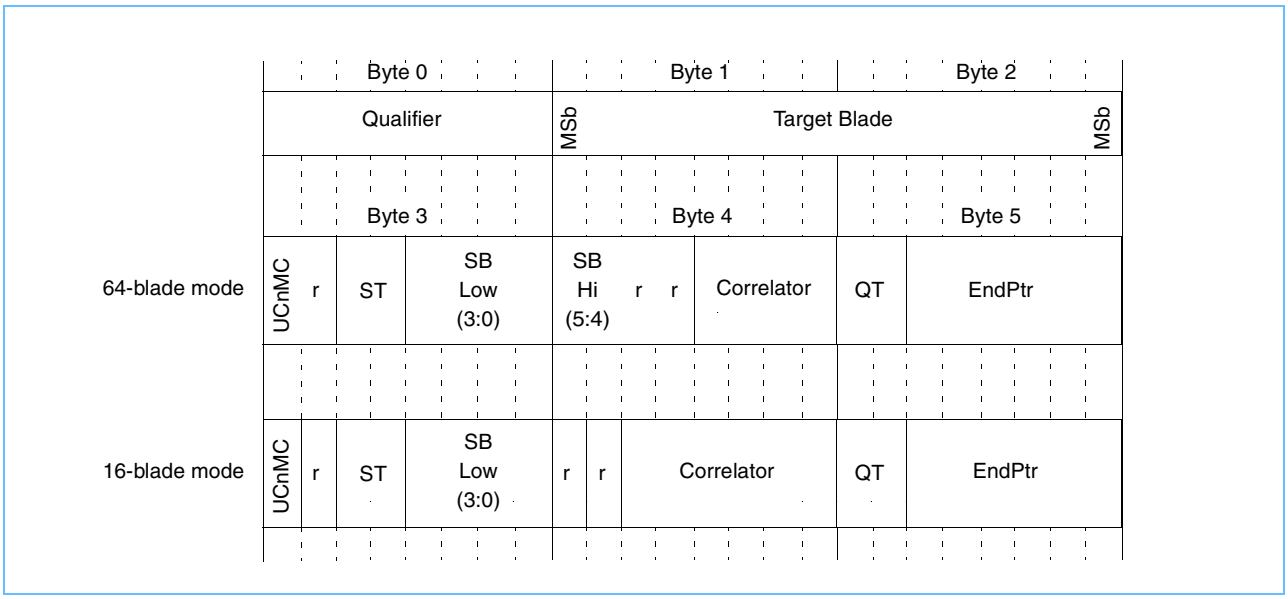


Table 5-1. Cell Header Fields (Page 1 of 2)

Field Name	Definition	Notes
Qualifier	This 8-bit field indicates the type of cell that is being transmitted. 7,2 Cell format value. The type of cell format used for this cell. '10' Frame format. Cell data is from a single frame (i.e., not packed, see below). '11' Packed frame format. The ST field must be set to '01', indicating the end of the current frame. The Endptr field indicates the location of the last byte of the current frame. The next frame starts on the next QW boundary. A frame may be packed only if it is unicast format, has the same priority and TB destination as the current frame, and is 49 bytes or larger. The correlator in the cell header cannot be the same value as the correlator in the frame header of the next frame found in the packed cell. All other values are reserved. 6 Switch cell header parity. This even parity bit covers the Qualifier and the TB fields. When a parity error is detected, the cell is discarded and the event is counted. Even parity is achieved when the number of bits in the cell header that contain a '1' is even. 5:4 Data cell indicator. '00' Idle cell '11' Data cell All other values are reserved. 3 Reserved. Set to '0'. 1:0 Cell Priority '00' Highest priority - used only for port mirroring traffic. '01' High priority traffic '10' Low priority traffic '11' Reserved	1 (cell format value) 3 (cell priority)
Target Blade	Target blade address (16-bit field). Encoding of this field depends on the target blade mode. 16-blade The Target Blade field is a bit map of the destination target blades. Target Blade 0 corresponds to the MSb of the Target Blade field. 64-blade Valid unicast target blade field encodes are 0 through 63. Multicast encodes are in the range of 512 through 65535.	2
UCnMC	Unicast - Multicast indicator. This 1-bit field indicates the format of the frame carried in this cell. '0' Multicast format. Guided traffic must be sent in multicast format. '1' Unicast format.	3
ST(1:0)	Frame State Indicator (2-bit field). Provides information about the status of the frame currently being carried in the cell. 00 Continuation of current frame (the cell contains a middle portion of a frame, but no start or end of a frame) 01 End of current frame. This code point must be used when the Cell format value is '11' (packed frame format). (The cell contains the end of frame if "frame format" is indicated by the cell format value, or the end of one frame and the beginning of another frame if "packed frame format" is indicated.) 10 Start of new frame (the cell contains the start of a frame, but no end of a frame) 11 Start and end of new frame. Used for frames 48 bytes or smaller. This code point is also used to indicate a reassembly abort command. Abort is indicated when the End Pointer field value is '0'. An aborted frame is discarded by the E-EDS. At the point of reassembly, cells for a frame are expected to follow a start, continuation (may not be present for short frames) and end sequence. Hardware in the E-EDS detects when this sequence is not followed and reports these errors in the Reassembly Sequence Error Count Register. Frames with reassembly sequence errors are discarded.	
SB	Source blade address. The size of this field depends on the blade operational mode and indicates the value of the source blade.	4

1. Qualifier bits 1 and 2 are used by the NP4GS3's reassembly logic.
2. On egress, this field contains the output grant status information used by the ingress scheduler.
3. This field is used by the egress reassembly logic in selection of the reassembly control block.
4. On egress, this field is copied into the correlator field in the frame header when stored in the egress data store. It is also used by the egress reassembly logic in selection of the reassembly control block.

Table 5-1. Cell Header Fields (Page 2 of 2)

Field Name	Definition	Notes
Correlator	The size of this field depends on the blade operational mode. See Hardware Reference Manual section 13.3 TB Mode Register (TB_Mode). 16-blade: Correlator values 0 - 63 are used for unicast traffic. Correlator values 0-31 are used for multicast traffic. 64-blade: Correlator values 0 - 15 are used for unicast traffic. Correlator values 0-7 are used for multicast traffic.	3
QT(1:0)	Queue Type (2-bit field). Used to determine the required handling of the cell and the frame. Bits 1:0 Description 0x User traffic that is enqueued into a data queue (GRx or GBx). 1x Guided traffic that is enqueued into the guided frame queue. x0 Cell may be dropped due to switch congestion. This may be used by the attached switch. NP4GS3 hardware does not take any action based on this value. x1 Cell may not be dropped due to switch congestion. This may be used by the attached switch. NP4GS3 hardware does not take any action based on this value. QT(0) is set to 1 by the I-SWI hardware when FC Info field of the frame header is set to x'F'.	
EndPtr	End Pointer (6-bit field). The EndPtr field is a byte offset within the cell which indicates the location of the last data byte of the current frame in the cell when the ST field indicates end of current frame (ST = '01' or '11'). Valid values of the EndPtr field are in the range of 6 through 63. An EndPtr value of 0 is used only with an ST value of '11' to indicate an abort command. Values of 1 through 5 are reserved. In all other cases (ST = '00' or '10'), this field contains sequence checking information used by the frame reassembly logic in the network processor. The sequence checking information consists of a sequence number placed into this field. The first cell of a frame is assigned a sequence number of 0. In a packed cell, the sequence number is not placed into the EndPtr field since the field must contain the end pointer for the preceding frame; the next cell for this frame will contain a sequence number of 1. Sequence numbers increment from 0 to 63 and will wrap if necessary.	
r	Reserved field, transmitted as '0' . Should not be modified or checked by the switch fabric.	

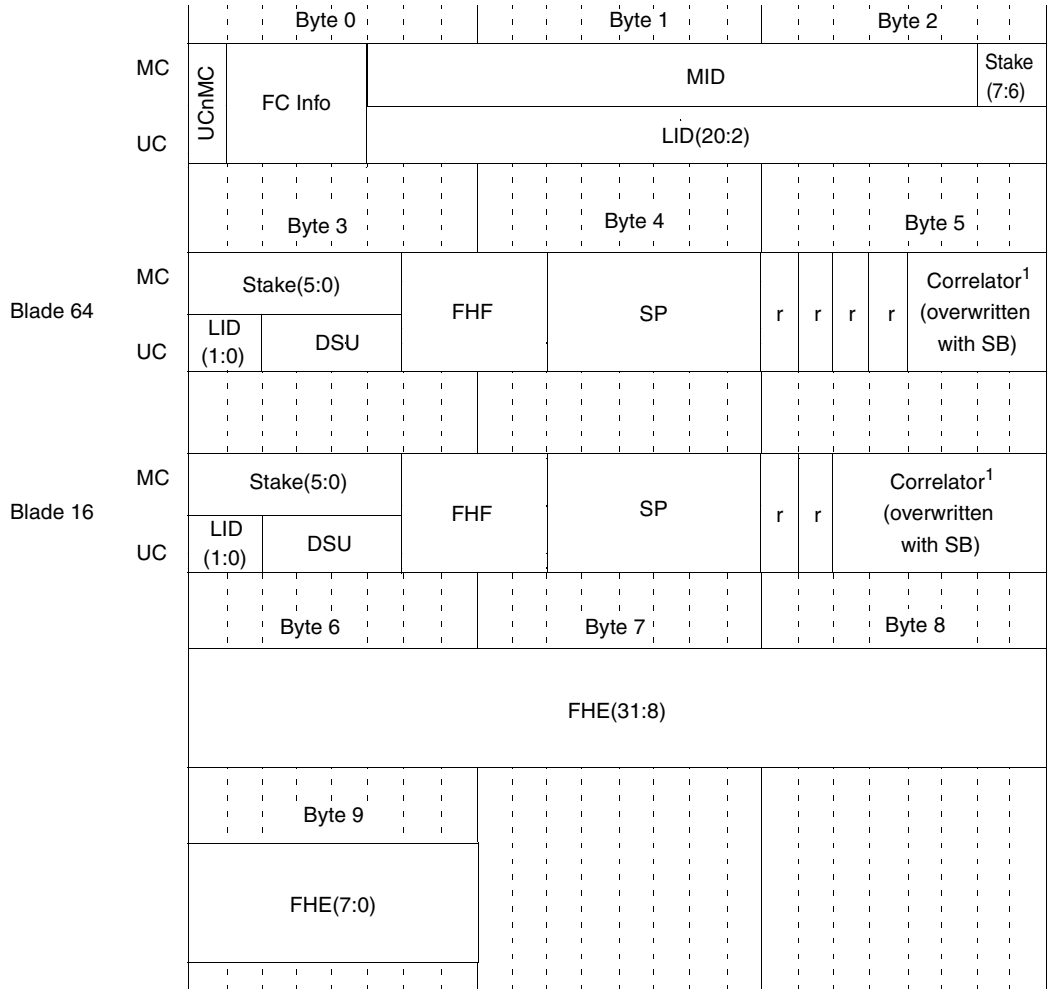
1. Qualifier bits 1 and 2 are used by the NP4GS3's reassembly logic.
2. On egress, this field contains the output grant status information used by the ingress scheduler.
3. This field is used by the egress reassembly logic in selection of the reassembly control block.
4. On egress, this field is copied into the correlator field in the frame header when stored in the egress data store. It is also used by the egress reassembly logic in selection of the reassembly control block.

5.1.2 Frame Header

A frame header is a 10-byte field containing control information used by the target network processor and is sent once per frame. A frame header can immediately follow the cell header, or with packing enabled, it can also be placed at the start of the 2nd (D10), 3rd (D26), or 4th (D42) QW of the cell.

Figure 5-3 illustrates the format of a frame header; *Table 5-2* provides the field definitions.

Figure 5-3. Frame Header Format



1. See description of the correlator field in *Frame Header Fields* on page 148.

Table 5-2. Frame Header Fields

Field Name	Description	Notes
UCnMC	Unicast - Multicast indicator. This 1-bit field indicates the format of the frame header. '0' Multicast format. '1' Unicast format.	1
FC Info	Flow Control Information (4-bit field). Indicates the type of connection used for this frame. Connection type encoding is used by the NP4GS3's flow control mechanisms.	2
LID	Lookup Identifier. Used by the egress processing to locate the necessary information to forward the frame to the appropriate target port with the correct QoS.	3
MID	Multicast Identifier. Used by the egress processing to locate the multicast tree information which is used to forward the frame to the appropriate target ports with the correct QoS.	3
Stake	Available only for the multicast format of the frame header. This 8-bit field is used by egress processing to locate the start of the Layer 3 header.	3
DSU	DSU indicator. Available only for the unicast format of the frame header. This 4-bit field indicates which egress data stores are used by this frame. Defined as follows (where "r" indicates a reserved bit that is transmitted as '0' and is not modified or checked on receipt): 0rr0 Data store 0 0rr1 Data store 1 1rr0 Data store 0 and data store 1 1rr1 Data store 0 and data store 1	
FHF	Frame Header Format. Software controlled field. This field, with the addition of the UC field, is used by the hardware classifier in the EPC to determine the code entry point for the frame. The UC field and the FHF form a 5-bit index into a configurable lookup table of code entry points used for egress processing.	
SP	Source port of the frame.	
FHE	Frame Header Extension (32-bit field). Used by ingress processing to pass information to egress processing. The contents of this field depend on the FHF value used by egress processing to interpret the field. Information passed reduces the amount of frame parsing required by egress processing when determining how to forward the frame.	
r	Reserved field, transmitted as '0' . Should not be modified or checked by the switch fabric.	
Correlator	The size of this field depends on the blade operational mode. The SB information in the cell header is copied into the byte occupied by the correlator (overlaying the correlator and some reserved bits) when the frame header is written to the egress data store. This provides SB information for egress processing. 16-blade Correlator values 0-63 are used for unicast traffic. Correlator values 0-31 are used for multicast traffic. 64-blade Correlator values 0-15 are used for unicast traffic. Correlator values 0-7 are used for multicast traffic.	

1. This field is used by egress reassembly logic in selection the reassembly control block. It is also used by the hardware classifier.
2. This field is passed through the ingress flow control before the frame is enqueued for transmission across the switch interface. It can be used by software to allow the hardware to make further flow control decisions on egress by passing connection information (type and DSCP).
3. This field is passed by the hardware but is defined and used by the software.

5.2 Ingress Switch Cell Interface

The Ingress Switch Cell Interface (I-SCI) provides a continuous stream of transmit data to the DASL. After power on or reset of the network processor, the I-SCI initialization process generates synchronization cells for the DASL. When the DASL is synchronized, the I-SCI enters the operational state. When there are no data cells to send, the I-SCI generates idle cells for transmission via the DASL. When there are data cells to send, the I-SCI receives a logical cell from the I-SDM, translates the cell into the switch cell format, and transmits the cell via the DASL. The I-SCI performs formatting on the cell headers to conform with the switch cell format.

The I-SCI unit relies on an internal FIFO buffer (written by the I-SDM at the network processor core clock rate and read at the Switch clock rate) performing the translation from logical cell format to switch cell format.

5.2.1 Idle Cell Format

When there is no data to send, idle cells are transmitted on the SWI. All bytes in an idle cell have the value x‘CC’, except for the first three bytes in the master stream. Word 0, Word 1, and Word 2 of the master stream contain H0, H1, and H2 respectively.

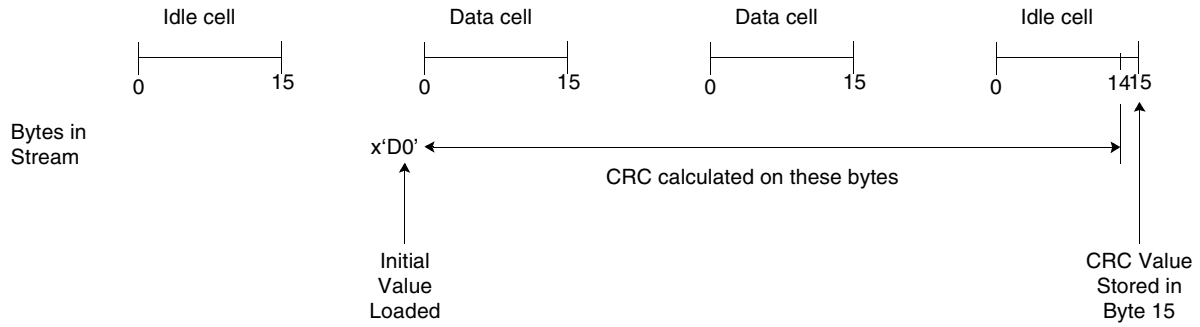
Table 5-3. Idle Cell Format Transmitted to the Switch Interface

Word #	Slave 1 (Byte 0)	Master (Byte 1)	Slave 3 (Byte 2)	Slave 2 (Byte 3)
	(bits 31:24)	(bits 23:16)	(bits 15:8)	(bits 7:0)
W0	x‘CC’	H0	x‘CC’	x‘CC’
W1	x‘CC’	H1 (x‘CC’)	x‘CC’	x‘CC’
W2	x‘CC’	H2 (x‘CC’)	x‘CC’	x‘CC’
W3	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W4	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W5	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W6	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W7	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W8	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W9	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W10	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W11	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W12	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W13	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W14	x‘CC’	x‘CC’	x‘CC’	x‘CC’
W15	CRC	CRC	CRC	CRC

5.2.1.1 CRC Bytes: Word 15

The cyclic redundancy check (CRC) bytes sent on each byte stream contain an 8-bit CRC checksum of the polynomial $X^8 + X^4 + X^3 + X^2 + 1$. Each byte stream is independently calculated and the initial value loaded into the CRC generator at the end of each idle cell (after Word 15) is x'D0'. The final CRC value is calculated starting with the first byte following an idle cell up to (but not including) the byte sent as part of Word 15 in the next idle cell. *Figure 5-4* illustrates an example of the CRC calculation.

Figure 5-4. CRC Calculation Example



5.2.1.2 I-SCI Transmit Header for the Idle Cell

The idle cell header consists of three bytes, H0, H1, and H2, which are defined as follows:

- H0. Also referred to as the Qualifier byte, this 8-bit field indicates the type of cell being transmitted.
- H1 and H2. Set to x'CC'.

The following table provides the field definitions for H0:

Bit(s)	Definition
7	Reserved. Transmitted as '0'.
6	Switch cell header parity. This even parity bit covers the H0-H2 fields.
5:4	Data cell indicator. '00' Idle cell '11' Data cell All other values are Reserved.
3:2	Reserved. Transmitted as '00'.
1:0	Reserved. This field should not be examined by the switch.

5.2.2 Switch Data Cell Format - Ingress and Egress

Table 5-4 shows the format of data cells sent to and from the SWI via the DASL bus. Notice that the Packet Routing Switch cell header bytes (H0, H1, and H2) are all contained in the master byte stream. Bytes designated CH0 through CH5 are the cell header bytes described in *Figure 5-2. Cell Header Format* on page 144.

Table 5-4. Switch Data Cell Format

Word #	Slave 1 DASL_Out_0 DASL_Out_1	Master DASL_Out_2 DASL_Out_3	Slave 3 DASL_Out_4 DASL_Out_5	Slave 2 DASL_Out_6 DASL_Out_7
	(bits 31:24)	(bits 23:16)	(bits 15:8)	(bits 7:0)
W0	CH5	CH0 (H0)	D9	D7
W1	D0	CH1 (H1)	D4	D2
W2	D1	CH2 (H2)	D5	D3
W3	CH4	CH3	D8	D6
W4	D25	D23	D21	D19
W5	D12	D10	D16	D14
W6	D13	D11	D17	D15
W7	D24	D22	D20	D18
W8	D41	D39	D37	D35
W9	D28	D26	D32	D30
W10	D29	D27	D33	D31
W11	D40	D38	D36	D34
W12	D57	D55	D53	D51
W13	D44	D42	D48	D46
W14	D45	D43	D49	D47
W15	D56	D54	D52	D50

1. DASL_Out_x (where x ∈ {1, 3, 5, 7}) carry the even bits of the indicated bytes.
2. DASL_Out_x (where x ∈ {0, 2, 4, 6}) carry the odd bits of the indicated bytes.
3. Dxx indicates the data byte in the cell from the SDM interface.
4. CHx indicates the cell header.

5.3 Data-Aligned Synchronous Link Interface

The data-aligned synchronous link (DASL) interface is a macro that facilitates high speed point-to-point inter-chip communication. It provides the application designer the ability to relieve I/O constraints imposed by the device package or card connector. The DASL interface performs multi-bit serialization and de-serialization to reduce the I/O pin count. The interface is frequency-synchronous, which removes the need for asynchronous interfaces that introduce additional interface latency. DASL links are intended to operate over a back-plane without any additional components.

The DASL interface macro was developed to interface the core area of a CMOS ASIC to a high speed link. The macro incorporates all the high-speed circuitry necessary to initialize and perform dynamic link timing and data serialization/de-serialization without exposing the core designer to the specific implementation. The core ASIC interface to DASL is a parallel interface. The DASL macro is scalable based on application needs.

The DASL macro was designed for high levels of integration. It uses reduced voltage differential transceivers to reduce power consumption. The macro has been partitioned such that multiple sub-macros share a common controller as well as a common phase-locked loop (PLL).

On the most basic level, the DASL macro is designed to provide a 4-to-1 serialization/de-serialization interface. The NP4GS3 application utilizes a 32- to 8-bit (32-bit port) pin reduction. The shared DASL controller (SDC) provides control for the DASL TX and DASL RX ports.

5.4 Egress Switch Cell Interface

The Egress Switch Cell Interface (E-SCI) receives cells from the switch fabric and passes data cells to the Egress Switch Data Mover (E-SDM). The E-SCI discards idle cells received from the switch fabric, checks the parity of the received cells, and discards cells with bad parity. The E-SCI strips out the target blade per-port grant information from the switch cells and sends this grant information to the network processor Ingress units for use in ingress data flow control. The E-SCI assists in egress data flow control by throttling the switch fabric to prevent data overruns.

5.4.1 Master and Multicast Grant Reporting

The master and multicast grant (Master_Grant and MC_Grant) I/O signals report congestion in the attached switch to the NP4GS3. When Master_Grant (see *Section Table 2-1. Signal Pin Functions* on page 38) indicates congestion, the ingress scheduler is disabled from sending any traffic to the switch interface. When Multicast_grant (see *Section Table 2-1. Signal Pin Functions* on page 38) indicates congestion, the Ingress Scheduler is disabled from sending any multicast traffic to the switch interface.

5.4.2 Output Queue Grant Reporting

Most fields in the cell header must pass through the switch fabric unchanged (idle cells are not transmitted through a switch fabric; they originate at the output port of the switch). The exception to this is the Target Blade field (see *Figure 5-2: Cell Header Format* on page 144) which contains Output Queue Grant (OQG) information used by the network processor's Ingress EDS when selecting data to be sent to the switch. A target port is not selected if its corresponding Output Queue Grant information is set to ‘0’.

Further, Output Queue Grant information is sent for each of the three priorities supported by the network processor. This is done using multiple cell transfers; starting with priority 0, reporting Output Queue Grant for all supported target blades, then repeating this process for each priority level until a value of 2 is reached, and starting over at priority 0 again.

For 16-blade operational mode, the sequence is:

1. Priority 0; OQG for blades 0:15 (H1 contains 0:7, H2 contains 8:15)
2. Priority 1; OQG for blades 0:15 (H1 contains 0:7, H2 contains 8:15)
3. Priority 2; OQG for blades 0:15 (H1 contains 0:7, H2 contains 8:15)
4. Start over at step 1.

The idle cell indicates the priority of the OQG it carries. This allows the network processor to synchronize with the external switch.

For 64-blade operational mode, the sequence is:

1. Priority 0; OQG for blades 0:15 (H1 contains 0:7, H2 contains 8:15)
2. Priority 0; OQG for blades 16:31 (H1 contains 16:23, H2 contains 24:31)
3. Priority 0; OQG for blades 32:47 (H1 contains 32:39, H2 contains 40:47)
4. Priority 0; OQG for blades 48:63 (H1 contains 48:55, H2 contains 56:63)
5. Priority 1; OQG for blades 0:15 (H1 contains 0:7, H2 contains 8:15)
6. Priority 1; OQG for blades 16:31 (H1 contains 16:23, H2 contains 24:31)
7. Priority 1; OQG for blades 32:47 (H1 contains 32:39, H2 contains 40:47)

8. Priority 1; OQG for blades 48:63 (H1 contains 48:55, H2 contains 56:63)
9. Priority 2; OQG for blades 0:15 (H1 contains 0:7, H2 contains 8:15)
10. Priority 2; OQG for blades 16:31 (H1 contains 16:23, H2 contains 24:31)
11. Priority 2; OQG for blades 32:47 (H1 contains 32:39, H2 contains 40:47)
12. Priority 2; OQG for blades 48:63 (H1 contains 48:55, H2 contains 56:63)
13. Start over at step 1.

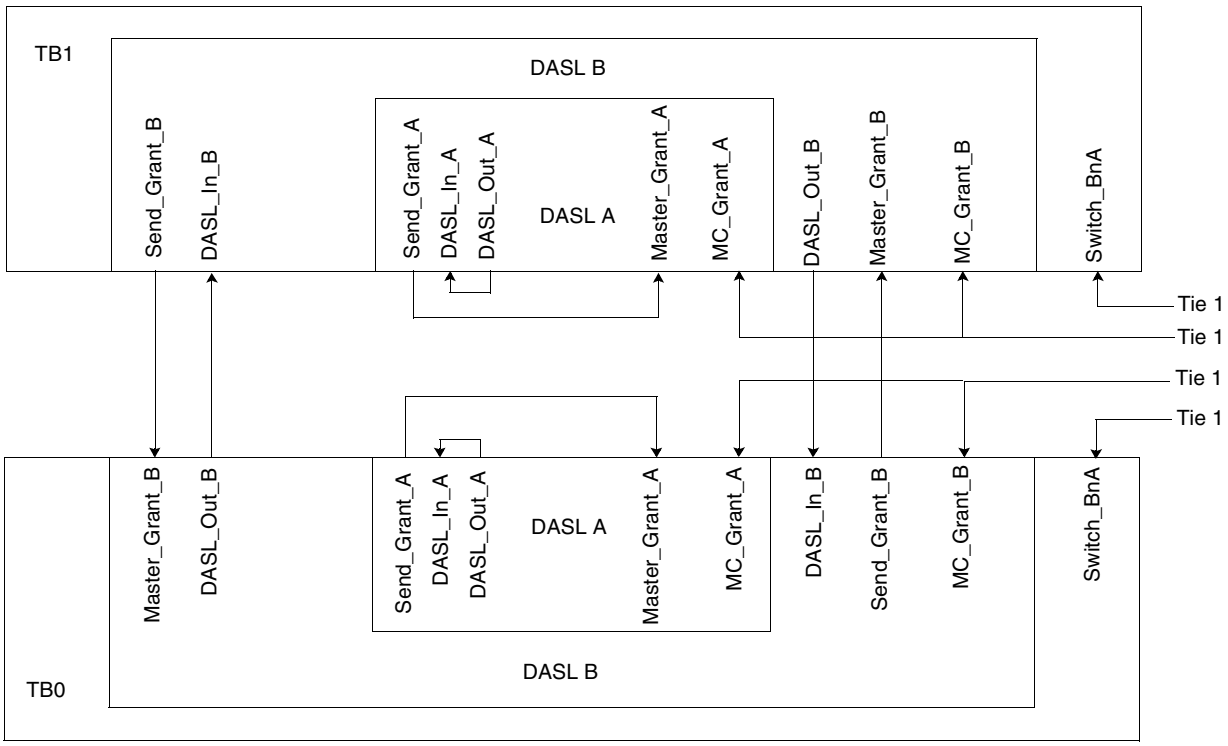
For 64-blade mode, this sequence is interrupted when an idle cell is sent. *Table 5-7* shows an idle cell that carries the OQG for all blades. Status for each priority is given in increasing order; (P0 followed by P1 followed by P2). The network processor restarts the sequence at step one with the arrival of the next data cell.

5.4.2.1 OQG Reporting in External Wrap Mode

When the NP4GS3 is configured for External Wrap mode (see bit 31 in Section *13.29.1 DASL Configuration Register (DASL_Config)* on page 502), OQG is not collected as described in *Section 5.4.2*. Instead, the master grant I/O signals are used to collect this information.

In this mode of operation, only target blades 0 and 1 are valid addresses. OQG status for all other blade addresses is always reported as zero to the Ingress Scheduler. Master_Grant_A is connected to Send_Grant_A of the same NP4GS3, while Master_Grant _B of one NP4GS3 is connected to Send_Grant_B of the other. Thus, the OQG status for TB0 is provided by Master_Grant_A on TB0 and from Master_Grant_B on TB1. The OQG status for TB1 is provided by Master_Grant_B on TB0 and from Master_Grant_A on TB1. Internally to both NP4GS3s, master grant is derived from the logical AND of both master grant I/O signals (per priority).

Figure 5-5. External Wrap Mode (Two NP4GS3 interconnected)

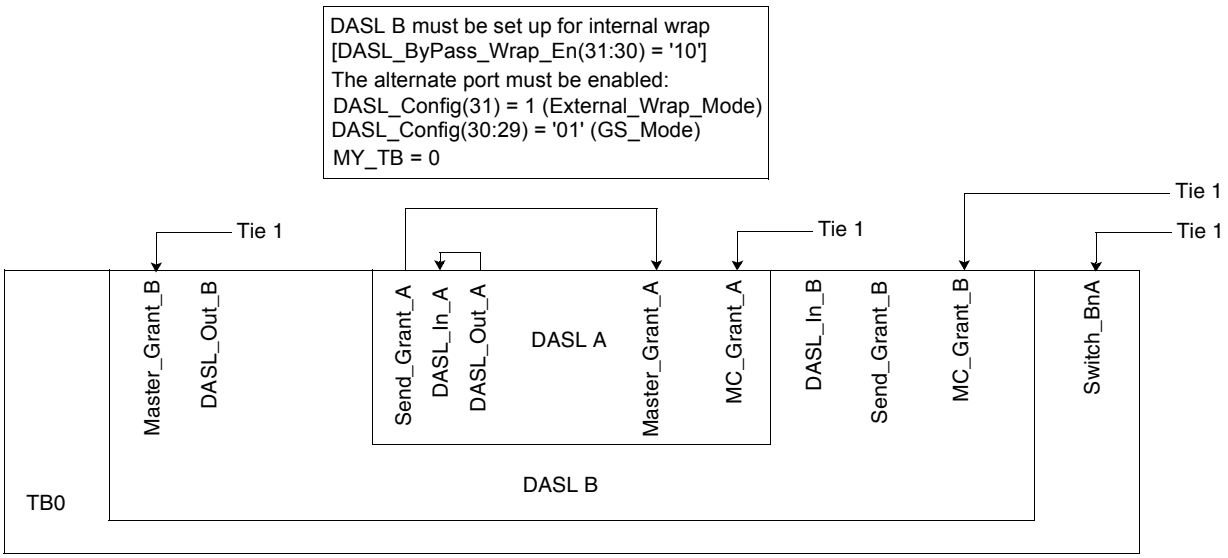


Note: In this configuration OQG status and Master Grant are not differentiated by priority.

Figure 5-6 on page 156 illustrates a single NP configuration. Note that in this configuration, the DASL A interface is used. With Switch_BnA tied to 1, this makes this interface the "Alternate" (See *13.29.1.1 Dynamic Switch Interface Selection* on page 504). Since the NP must have the "Primary" active, even though it is not used in this configuration, DASL_Bypass_Wrap must be enabled for the DASL B interface (*13.29.2 DASL Bypass and Wrap Register (DASL_Bypass_Wrap)* on page 506) for proper operation.

My_TB is set to 0 for this blade, and both OQG status and internal Master Grant is provided by Master_Grant_A.

Figure 5-6. External Wrap Mode (single NP4GS3 configuration)



Note: In this configuration OQG status and Master Grant are not differentiated by priority.

5.4.3 Switch Fabric to Network Processor Egress Idle Cell

The Egress SWI Interface requires idle cells when there is no data. An idle cell requires:

- The last bytes on each stream contain a Trailer cyclic redundancy check (CRC).
- For the master stream, the header H0 as described in *Table 5-5* on page 157.
- For the master stream, H1 - H2 contain the target blade grant priority information when in 16-blade mode.
- For the master stream, H1 - H2 contain x‘CC’ when in 64-blade mode.
- All other bytes contain x’CC’ when in 16-blade mode or OQG (see *Table 5-6* on page 157) when in 64-blade mode.

Table 5-5. Receive Cell Header Byte H0 for an Idle Cell

Bit(s)	Definition
7	Reserved. Transmitted as '0'.
6	Switch cell header parity. This even parity bit covers the H0-H2 fields.
5:4	Data cell indicator. '00' Idle cell '11' Data cell All other values are Reserved.
3:2	Reserved. Transmitted as '00'.
1:0	Output Queue Grant priority. When in 16-blade mode, indicates the priority level of the Output Queue Grant information carried in H1-H2. Otherwise the network processor ignores this field.

Table 5-6. Idle Cell Format Received from the Switch Interface - 16-blade Mode

Slave 1	Master 1	Slave 3	Slave 2
Byte 0	Byte 1	Byte 2	Byte 3
x'CC'	H0	x'CC'	x'CC'
x'CC'	H1 (OQG (0:7))	x'CC'	x'CC'
x'CC'	H2 (OQG (8:15))	x'CC'	x'CC'
x'CC'	x'CC'	x'CC'	x'CC'
x'CC'	x'CC'	x'CC'	x'CC'
x'CC'	x'CC'	x'CC'	x'CC'

5.4.4 Receive Header Formats for Sync Cells

Sync cells are a special type of idle cells. They are similar to the received idle cell for 16-blade mode (see *Table 5-6* on page 157) but H0, H1, and H2 are set to a value of x‘CC’. All sync cells are discarded.

5.5 Egress Switch Data Mover

The Egress Switch Data Mover (E-SDM) is the logical interface between the switch cell data flow of the E-SCI and the frame data flow of the Egress EDS. The E-SDM serves as a buffer for cells flowing from the E-SCI to the Egress EDS. The E-SDM extracts control information, such as the frame correlator, which is passed to the Egress EDS. The Egress EDS uses this control information, along with data from the E-SDM, to re-assemble the cells into frames.

6. Egress Enqueuer / Dequeuer / Scheduler

The Egress Enqueuer / Dequeuer / Scheduler (Egress EDS) interfaces with the Physical MAC Multiplexer (PMM), the Embedded Processor Complex (EPC), and the Egress Switch Interface (Egress SWI). It is responsible for handling all the buffer, frame, and queue management for reassembly and transmission on the egress side of the network processor.

The Egress EDS reassembles data that have been transported from a switch fabric through the data-aligned synchronous link (DASL) interface to the Egress PMM. It reassembles frames sent from up to 64 network processors (up to 3072 simultaneous reassemblies). Each switch cell received from the Egress SWI is examined and stored in the appropriate Egress Data Store (Egress DS) for reassembly into its original frame. When the frame is completely received from the SWI, the Egress EDS enqueues it to the EPC for processing.

Once the EPC processes the frame, it provides forwarding and quality of service (QoS) information to the Egress EDS. The Egress EDS then invokes hardware configured flow control mechanisms and then enqueues it to either the Scheduler, when enabled, or to a target port (TP) queue for transmission to the Egress PMM (which, in turn, sends the data to physical layer devices).

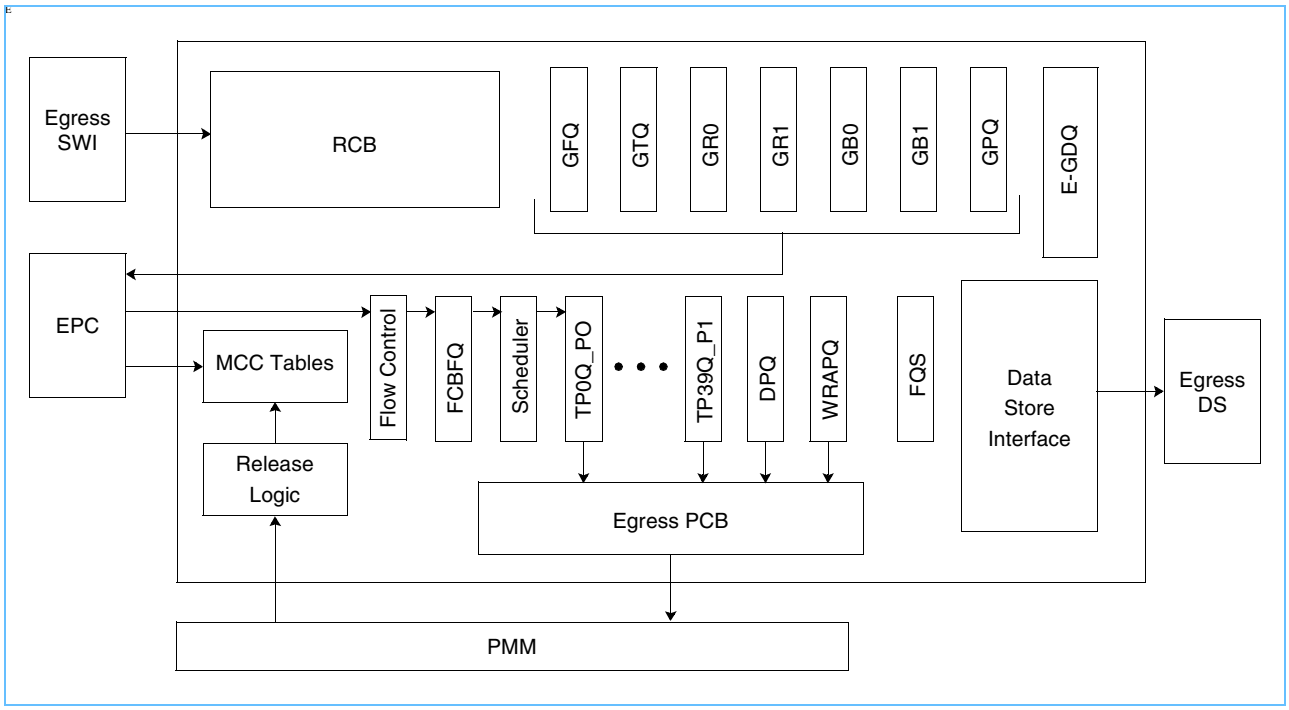
The Egress EDS supports the following functions, as illustrated in *Figure 6-1* on page 162:

- External Egress Data Store
- Automatic allocation of buffer and frame control blocks for each frame
- EPC queues (GFQ, GTQ, GR0, GR1, GB0, GB1, and GPQ)
- Target port queues with two priorities
- Buffer thresholds and flow control actions
- Bandwidth and best effort scheduling
- Reading and writing of frame data stored in Egress Data Store
- Up to 512 K buffer twins depending on memory configuration
- Up to 512 K of frame control blocks (FCBs) depending on memory configuration
- Unicast and multicast frames
- Cell packing
- 40 external ports plus wrap port interface to the PMM
- Discard function
- Hardware initialization of internal and external data structures

6.1 Functional Blocks

Figure 6-1 illustrates the functional blocks of the Egress EDS. The list following the figure explains each functional block.

Figure 6-1. Egress EDS Functional Blocks



Data Store Interface	Writes the external Egress DS during frame reassembly and reads them during frame transmission. Also gives the EPC access to the Egress DS. The Data Store Interface supports two external data stores: DS0 and DS1.
DPQ	Discard Port Queue. Releases twin buffers back to the free queue stack. The picocode uses this queue to discard frames where header twins have been allocated.
E-GDQ	Discard Queue Stack. Holds frames that need to be discarded. The hardware uses this queue to discard frames when the egress DS is congested or to re-walk a frame marked for discard for a half-duplex port. The picocode uses this queue to discard frames that do not have header twins allocated.
Egress PCB	Egress Port Control Block. Contains the necessary information to send a frame to the Egress PMM for transmission. The Egress EDS uses this information to walk the twin buffer chain and send the data to the Egress PMM's output port. There is a PCB entry for each target port, plus one for Discard and one for Wrap. Each entry holds information for two frames: the current frame being sent to the PMM port and the next frame to be sent.

FCBFQ	Frame Control Block Free Queue. Lists free Egress FCBs. FCBs store all the information needed to describe the frame on the egress side, such as starting buffer, length, MCC address, frame alteration, and so on. The Egress EDS obtains an FCB from the free queue when the EPC enqueues the frame to either a flow QCB (see *Flow Queues* on page 176) or a TP after EPC processing and flow control actions are complete.
FQS	Free Queue Stack. Holds a list of free egress twin buffers which are used by the Egress EDS during frame reassembly and by the EPC during frame alteration. The twin buffers store the frame data or frame alteration header twins and also contain the link pointer to the next buffer in the chain. The FQS obtains a new free twin buffer any time the Egress EDS needs one and returns free twin buffers after frames are discarded or transmitted.
GB0, GB1	Low Priority Data Queues. GB0 is for frames stored in Egress DS0. GB1 is for frames stored in Egress DS1.
GFQ	Guided Frame Queue. Queue that contains guided frames for delivery for the Egress side of the network processor to the Guided Frame Handler.
GPQ	PowerPC queue. Queue that contains frames re-enqueued for delivery to the General PowerPC Handler (GPH) thread for processing.
GR0, GR1	High Priority Data Queues. GR0 is for frames stored in Egress DS0. GR1 is for frames stored in Egress DS1.
GTQ	General Table Queue. Queue that contains guided frames re-enqueued by picocode for delivery to the General Table Handler (GTH) thread.
MCC Table	Multicast Count Table. Each entry stores the number of multicast frames associated with a particular set of twin buffers. If a frame is to be multicast to more than one target port, the EPC enqueues the frame to each target port, causing an entry in the MCC Table to be incremented. As each target port finishes its copy of the frame, the MCC Table entry is decremented. When all ports have sent their copies of the frame, the associated twin buffers are released.
RCB	Reassembly Control Block. Used by the Egress EDS to reassemble the cells received from the switch fabric into their original frames. Contains pointers to the Egress DS to specify where the contents of the current cell should be stored. Helps the Egress EDS keep track of the frame length and which EPC queue to use.
Release Logic	Releases twin buffers after the PMM has finished with the contents of the buffer. The Release Logic checks the MCC Table to determine if the buffer can be released or is still needed for some other copy of a multicast frame.
TP0Q - TP39Q	Target Port Queues. Hold linked lists of frames destined for a TP. Two queues are associated with each of the 40 possible TPs. These queues are prioritized from high (P0) to low (P1) using a strict priority service scheme (all higher priority queues within a target port set must be empty before starting a lower priority queue).

WRAPQ	Wrap Queue. Two wrap queues, one for guided frames and one for data frames, send frames from the egress side to the ingress side of the network processor. These queues allow the network processor to respond to a guided frame sent from a remote control point function (CPF). The guided frame is received from the switch fabric on the egress side and is wrapped to the ingress side to allow a response to be sent to the CPF across the switch fabric. A data frame may be wrapped when processing on a remote CPF is required.

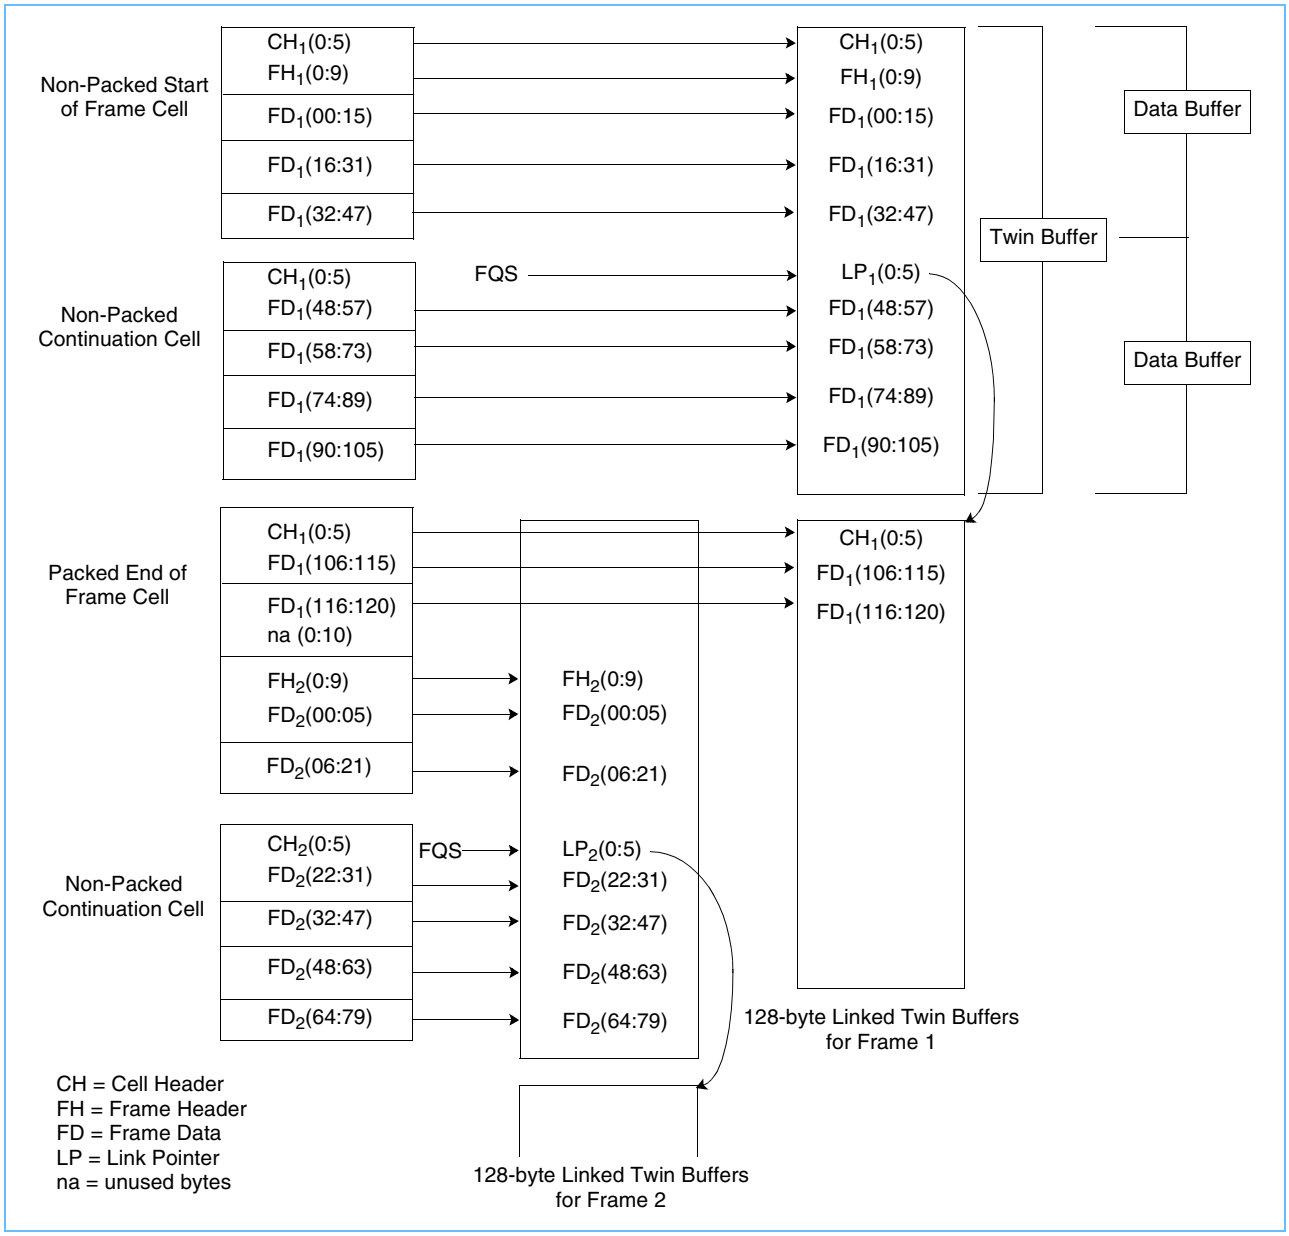
6.2 Operation

The Egress EDS receives switch cells from the Egress Switch Interface (SWI) along with information that has been preprocessed by the Egress Switch Data Mover (SDM) such as the Reassembly Correlator, source blade, multicast indication, priority, and target data store (DS). In order to optimize the data transfer to an Egress DS, the Egress EDS uses the target DS's information to determine which Egress SDM to service. The two Egress DSs, DS0 and DS1, use alternating write windows, meaning the Egress EDS can write one cell to one data store each "cell window time" (the time needed to store an entire switch cell (64 bytes) in external DRAM). Cell window time is configured using the DRAM Parameter Register's 11/10 field.

After the appropriate Egress SDM has been selected, the Egress EDS reads the cell data out of the SDM and uses the Reassembly Correlator, source blade, multicast indication, and priority information to index into the Reassembly Control Block (RCB). The RCB contains all the information needed to reassemble the frame, including the buffer address to use in the Egress DS. The cell data is stored in the buffer and the RCB is updated to prepare for the next cell associated with the same frame. The Egress EDS manages 3072 RCB entries, and each entry contains information such as start-of-frame indicator, data store buffer address, current reassembled frame length, and queue type. Cells from several source blades are interleaved coming from the SWI, and the Egress EDS uses the RCB information to rebuild each frame.

The Egress EDS uses a free buffer from the head of the free queue stack (FQS) as needed to store frame data in the Egress DS. The Egress EDS stores the cell data in the appropriate buffer and also stores the buffer chaining information over the cell header data. When a packed cell arrives, the Egress EDS stores each frame's information in two separate twin buffers. The first portion of the packed cell contains the end of a frame. This data is stored in the appropriate twin buffer as pointed to by the RCB. The remaining portion of the packed cell is the beginning of another frame and this data is stored in a second twin buffer as indicated by the second frame's RCB entry. *Figure 6-2* illustrates the cell buffers and storage in an Egress DS.

Figure 6-2. Cell Formats and Storage in the Egress DS



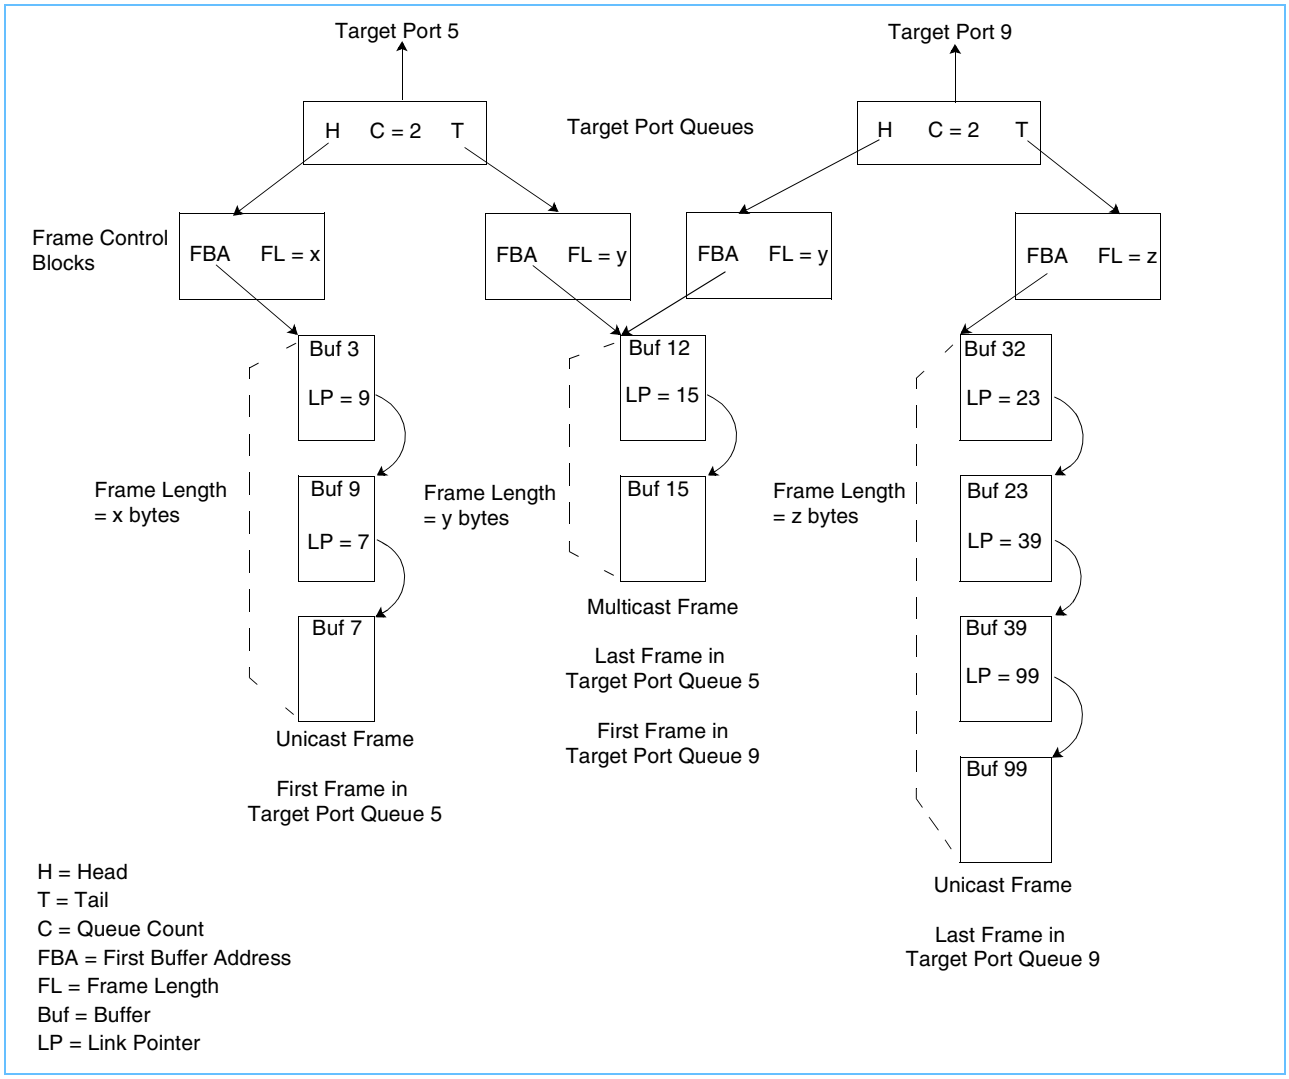
When the entire frame is reassembled, the Egress EDS enqueues it to one of several EPC queues. If the reassembled frame is a guided frame, the Egress EDS uses the GFQ. High priority frames are placed in either the GR0 or the GR1. Low priority frames are placed in either the GB0 or the GB1. The EPC services these queues and requests a programmable amount of read data from the various frames in order to process them (see *Table 7-78: Port Configuration Memory Content* on page 274). The Egress EDS reads the data from the Egress Data Store and passes it back to the EPC. Additional reads or writes can occur while the EPC is processing the frame. The Egress EDS performs all necessary reads or writes to the Egress Data Store as requested by the EPC.

When the frame has been processed, the EPC enqueues the frame to the Egress EDS. If the frame's destination is the General Table Handler (GTH), the Egress EDS enqueues the frame to the GTQ. If the frame is to

be discarded, it is placed in the DPQ. If the frame needs to be wrapped to the Ingress side, it is placed in the Wrap Queue. All other frames are subject to flow control actions. If flow control does not discard the frame, the frame is placed into the Scheduler, if enabled, or placed directly into a target port queue. Each target port supports two priorities and therefore has two queues. The EPC indicates which target port and which priority should be used for each frame enqueued. The two queues per port use a strict priority scheme, which means that all high priority traffic must be transmitted before any lower priority traffic will be sent.

Frames destined for the Scheduler, target ports, or wrap ports have a frame control block (FCB) assigned by the Egress EDS. The FCB holds all the information needed to transmit the frame including starting buffer address, frame length, and frame alteration information, as illustrated in *Figure 6-3*. If the EPC needs to forward more than one copy of the frame to different target ports, an entry in the MCC Table is used to indicate the total number of copies to send. The EPC enqueues the frame to different target ports or different flow QCBs and each enqueue creates a new FCB with (possibly) its own unique frame alteration.

Figure 6-3. TPQ, FCB, and Egress Frame Example



When a frame reaches the head of a target port queue, it is placed in the Egress Port Control Block (PCB) entry for that port and the FCB for that frame is placed on the FCB Free Queue. The Egress EDS uses the PCB to manage frames being sent to the PMM for transmission. The PCB stores information needed to retrieve frame data, such as current buffer address and frame length, from the Egress DS. The PCB allows up to 40 frames to be retrieved simultaneously from the Egress DS. The PCB also supports the Wrap Port and the Discard Port Queue. As data is retrieved from the Egress DS and passed to the PMM, the PCB monitors transfers and stores buffer link pointers that enable the PCB to walk the buffer chain for the frame. When the entire buffer chain has been traversed, the PCB entry is updated with the next frame for that target port.

As the PMM uses the data from each buffer, it passes the buffer pointer back to the Release Logic in the Egress EDS. The Release Logic examines the MCC Table entry to determine if the buffer should be returned to the FQS. (Half-Duplex ports will not have their twin buffers released until the entire frame has been transmitted, in order to to support the recovery actions that are necessary when a collision occurs on the Ethernet media.) If the MCC entry indicates that no other copies of this frame are needed, the buffer pointer is stored in the FQS. However, if the MCC entry indicates that other copies of this frame are still being used, the Egress EDS decrements the MCC entry, but does no further action with this buffer pointer.

The DPQ contains frames that have been enqueued for discard by the EPC and by the Release Logic. The hardware uses the DPQ to discard the last copy of frames transmitted on half duplex ports. The DPQ is dequeued into the PCB's discard entry, where the frame data is read from the DS to obtain buffer chaining information necessary to locate all twin buffers of the frame and to release these twin buffers back to the free pool (FQS).

6.3 Egress Flow Control

Flow control (whether to forward or discard frames) in the network processor is provided by hardware assist mechanisms and picocode that implements a selected flow control algorithm. In general, flow control algorithms require information about the congestion state of the data flow, including the rate at which packets arrive, the current status of the data store, the current status of target blades, and so on. A transmit probability for various flows is an output of these algorithms.

The network processor implements flow control in two ways:

- Flow control is invoked when the frame is enqueued to either a target port queue or a flow queue control block (QCB). The hardware assist mechanisms use the transmit probability along with tail drop congestion indicators to determine if a forwarding or discard action should be taken during frame enqueue operation. The flow control hardware uses the picocode's entries in the egress transmit probability memory to determine what flow control actions are required.
- Flow control is invoked when frame data enters the network processor. When the Egress DS is sufficiently congested, these flow control actions discard all frames. The threshold that controls the invocation of these actions is FQ_ES_Threshold_0 (see *Table 6-1: Flow Control Hardware Facilities* on page 168 for more information).

6.3.1 Flow Control Hardware Facilities

The hardware facilities listed in *Table 6-1* are provided for the picocode's use when implementing a flow control algorithm. The picocode uses the information from these facilities to create entries in the Egress transmit probability memory. The flow control hardware uses these entries when determining what flow control actions are required.

Table 6-1. Flow Control Hardware Facilities (Page 1 of 2)

Name	Definition	Access
Free Queue Count	Instantaneous count of the number of free twins available in the Egress Data Store.	CAB
FQ_ES_Threshold_0	Threshold for Free Queue Count. When the Free Queue Count < FQ_ES_Threshold_0, no further twins are allocated for incoming data. User packets that have started reassembly are discarded when they receive data when this threshold is violated. Guided traffic is not discarded. The number of packets discarded is counted in the Reassembly Discard Counter. When this threshold is violated, an interrupt (Class 0, bit 4) is signaled.	CAB
FQ_ES_Threshold_1	Threshold for Free Queue Count. When the Free Queue Count < FQ_ES_Threshold_1, an interrupt (Class 0, bit 5) is signaled.	CAB
FQ_ES_Threshold_2	Threshold for Free Queue Count. When the Free Queue Count < FQ_ES_Threshold_2, an interrupt (Class 0, bit 6) is signaled, and if enabled by DMU configuration, the Ethernet MAC preamble is reduced to 6 bytes.	CAB
Arrival Rate Counter	The arrival rate of data into the Egress Data Store. This counter increments each time there is a dequeue from the Twin Free Queue. When read by picocode via the CAB, this counter is set to 0 (Read with Reset).	CAB
FQ Count EWMA	The calculated EWMA of the Free Queue Count.	CAB
P0 Twin Count	The number of Twins in priority 0 packets that have been enqueued to flow queues, but have not been dequeued from target port queues.	CAB
P1 Twin Count	The number of twins in priority 1 packets that have been enqueued to flow queues, but have not been dequeued from target port queues.	CAB
P0 Twin Count Threshold	Threshold for P0 Twin Count. It is used when determining flow control actions against Priority 0 traffic. When P0 Twin Count > P0 Twin Count Threshold, the flow control hardware will discard the frame.	CAB
P1 Twin Count Threshold	Threshold for P1 Twin Count. It is used when determining flow control actions against Priority 1 traffic. When P1 Twin Count > P1 Twin Count Threshold, the flow control hardware will discard the frame.	CAB
Egress P0 Twin Count EWMA	The calculated EWMA based on the count of the number of twins allocated to P0 traffic during the sample period. Hardware maintains a count of the number of twins allocated to P0 traffic at enqueue.	CAB
Egress P1Twin Count EWMA	The calculated EWMA based on the count of the number of twins allocated to P1 traffic during the sample period. Hardware maintains a count of the number of twins allocated to P1 traffic at enqueue.	CAB
Egress P0 Twin Count EWMA Threshold	The congestion status of the Egress Data Store in each target blade. It is the result of a comparison between this configured threshold and the EWMA of the offered rate of priority 0 traffic (P0 Twin Count EWMA > P0 Twin Count EWMA threshold). This information is transmitted to remote blades via the res_data I/O and is collected in the Remote TB Status 0 register in the ingress flow control hardware.	CAB

Table 6-1. Flow Control Hardware Facilities (Page 2 of 2)

Name	Definition	Access
Egress P1 Twin Count EWMA Threshold	The congestion status of the Egress Data Store in each target blade. It is the result of a comparison between this configured threshold and the EWMA of the offered rate of priority 0 traffic. (P1 Twin Count EWMA > P1 Twin Count EWMA threshold). This information is transmitted to remote blades via the res_data I/O and is collected in the Remote TB Status 1 register in the ingress flow control hardware.	CAB
Target Port PQ+FQ_Th	Target Port port queue plus egress scheduler (flow QCB) threshold. The target port queues maintain a count of the number of twins allocated to the target port. The count is incremented on enqueue (after flow control transmit action is taken) and decremented on dequeue from the target port. Thresholds for each priority can be configured for for all ports (0:39). When the number of twins assigned to a target port queue exceeds the threshold, its threshold exceed status is set to 1. The status is used to index into the transmit probability memory for packets going to the target port.	CAB
QCB Threshold	Flow queue threshold. When the number of twins assigned to this flow queue exceeds this threshold, the threshold exceed status is set to 1. The status is used to index into the transmit probability memory.	CAB

6.3.2 Remote Egress Status Bus

The Remote Egress Status (RES) Bus communicates the congestion state of the Egress Data Stores of all nets in a system to the Ingress Flow Control of every NP4GS3 in that system. The ingress portion of each NP4GS3 can then preemptively discard frames destined for a congested NP4GS3 without consuming additional bandwidth through the switch.

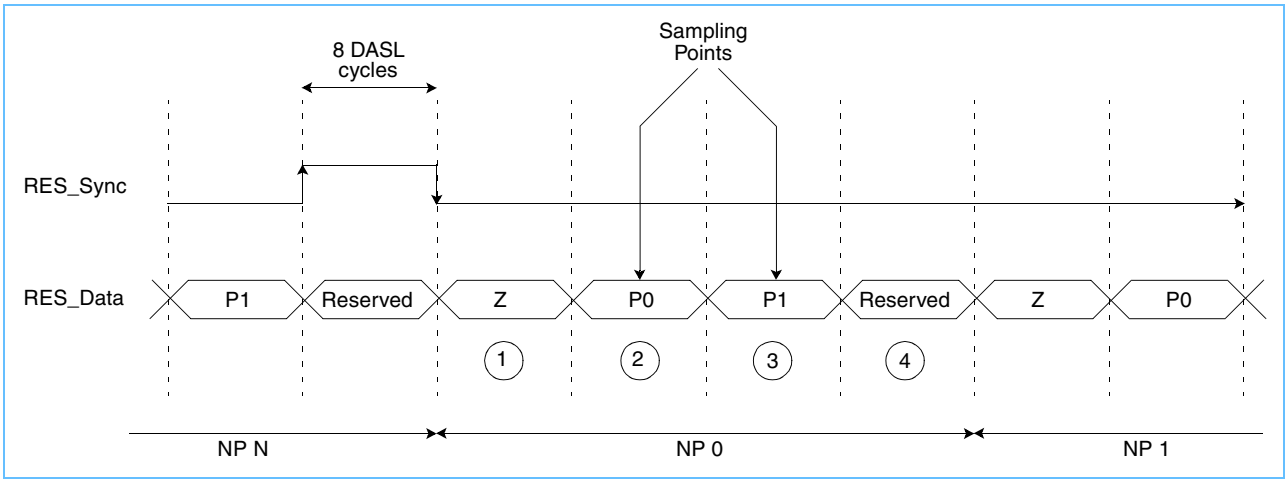
6.3.2.1 Bus Sequence and Timing

The RES Bus consists of two bidirectional signals:

1. **RES_Data**. This signal is time-division multiplexed between all the NP4GS3s in a system. Only one NP4GS3 at a time drives this signal. Each NP4GS3 drives two priorities of congestion status sequentially. All of the NP4GS3s in a system sample this data and store it for use by the Ingress Flow Control to make discard decisions.
2. **RES_Sync**. This signal is received by all NP4GS3s in a system. Each NP4GS3 samples the negative edge of this signal to derive its time slot to drive Egress data store congestion information. This signal is periodic and repeats to allow the NP4GS3s to resynchronize after 16 or 64 time slots have passed, depending on the value of the TB Mode register. In a system, one NP4GS3 can be configured to drive this signal to the other NP4GS3s. Alternatively, an external device can provide the stimulus for this signal.

Figure 6-4 shows a timing diagram of the operation of the RES Bus.

Figure 6-4. RES Bus Timing



The RES Bus operates on the same clock frequency as the internal DASL clock. This clock period can range from 8 ns to 10 ns. However, the RES Bus clock is not necessarily in phase with the DASL clock. In addition, each NP4GS3 is not necessarily in phase with other NP4GS3s in the same system. The RES_Sync signal is responsible for synchronizing all the NP4GS3s' usage of the RES data bus.

The RES Bus is time-division multiplexed between every NP4GS3 in the system. Each NP4GS3 moves its congestion information onto the RES Bus in the order of its My_TB register (that is, the NP4GS3 with a My_TB setting of 0 drives immediately after the fall of RES_Sync, followed by the NP4GS3 with a My_TB setting of 1, and so on).

Within each NP4GS3 time slot, the NP4GS3 puts four values on the RES_Data signal. Each value is held for eight DASL clock cycles. Therefore, each NP4GS3 time slot is 32 DASL clock cycles. The protocol for sending the congestion information is as follows:

1. **High-Z**. The NP4GS3 keeps its RES_Data line in high impedance for eight DASL clock cycles. This allows the bus to turn around from one NP4GS3 to another.
2. **P0**. The NP4GS3 drives its Priority 0 (P0) Egress Data Store congestion information for eight DASL clock cycles. This status is highwhen the Egress P0 Twin Count EWMA register value is greater than the Egress P0 Twin Count EWMA Threshold register value. It is low otherwise.
3. **P1**. The NP4GS3 drives its Priority 1 (P1) Egress Data Store congestion information for eight DASL clock cycles. This status is high when the Egress P1 Twin Count EWMA register value is greater than the Egress P1 Twin Count EWMA Threshold register value. It is low otherwise.
4. **Reserved**. The NP4GS3 drives a low value for eight DASL clock cycles. This is reserved for future use.

The Ingress Flow Control samples RES_Data during the midpoint of its eight DASL clock cycles. This provides a large enough sample window to allow for jitter and phase differences between the DASL clocks of two different NP4GS3s.

The RES_Sync signal is driven high during the Reserved cycle of the last NP4GS3's time slot. The RES_Sync signal therefore has a period equal to 32 DASL clock periods multiplied by the number of NP4GS3s supported in this system. The number of NP4GS3s can be either 16 or 64 depending on the value of the TB Mode register.

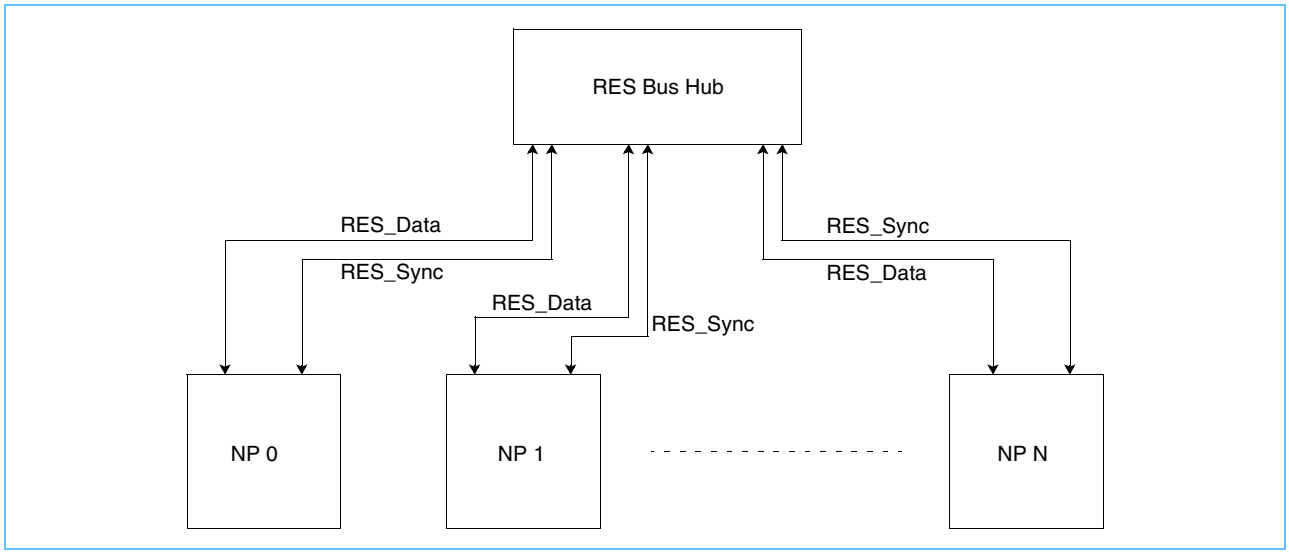
6.3.2.2 Configuration

The RES Bus is activated by enabling the ingress and egress functions of the internal RES data logic via the RES_Bus_Configuration_En register. Three bits in this register enable different functions:

- The I_RES_Data_En bit enables the ingress logic to capture the RES_Data.
- The E_RES_Data_En bit enables the egress logic to send its status on RES_Data.
- The E_RES_Sync_En bit enables one of the NP4GS3s to drive RES_Sync.

In a standard blade configuration (one NP4GS3 on each blade in a system), the RES Bus supports up to two NP4GS3s without using external transceivers. The RES_Sync and RES_Data lines are wired together, and one of the NP4GS3s is configured to drive RES_Sync. If, however, more than two NP4GS3s are to coexist in a system and external transceivers are NOT used, a hub-based configuration must be implemented. *Figure 6-5* shows such a configuration.

Figure 6-5. Hub-based RES Bus configuration to support more than two NP4GS3s



The hub is necessary to drive the required signal strength to all of the NP4GS3s in a system when not using external transceivers, and is connected point-to-point to each NP4GS3. The hub collects all RES_Data information from the Egress logic of every NP4GS3 and then distributes it based on the timing diagram in *Figure 6-5* to every NP4GS3's Ingress logic. The RES_Sync signal may be generated by either a solitary NP4GS3 or by the hub itself in this configuration.

6.3.3 Hardware Function

6.3.3.1 Exponentially Weighted Moving Average

The hardware generates exponentially weighted moving average (EWMA) values for the Free queue count and the P0/P1 twin counts, thus removing the burden of this calculation from the picocode. In general, EWMA for a counter X is calculated as follows:

EWMA_X = (1 - K) * EWMA_X + K * X

This calculation occurs for a configured sample period and K $\in$ {1, 1/2, 1/4, 1/8}.

6.3.3.2 Flow Control Hardware Actions

When the picocode enqueues a packet to be transmitted to a target port, the flow control logic examines the state of the target port PQ+FQ_Th, and the priority of the enqueued packet to determine if any flow control actions are required.

- If the FCInfo field of the FCBPage of the enqueued packet is set to x'F', flow control is disabled and the packet is forwarded without regard to any of the congestion indicators.
- For priority 0 packets, if target port PQ+FQ_Th or P0 Twin Count Threshold is exceeded, then the packet is discarded. The picocode must set up a counter block to count these discards.
- For priority 1 packets, if P1 Twin Count Threshold is exceeded, then the packet will be discarded. Otherwise the transmit probability found in the QCB (available only when the Scheduler is enabled) and the transmit probability table are accessed. The smaller of these values is compared against a random number ($\in$ { 0 ... 1}) generated by the hardware. When the transmit probability is zero or is less than the random number, the packet is discarded. The picocode must set up a counter block to count these discards.

The index into the transmit probability table is TTCCFP, where:

TT	Packet type (Egress FCBpage FCInfo field bits 3:2).
CC	DSCP assigned color (Egress FCBpage FCInfo field bits 1:0)
F	Threshold exceeded status of the target flow queue (QCB threshold exceeded)
P	Threshold exceeded status of the target port queue (Target port Pq+FQ_th exceeded)

6.4 The Egress Scheduler

The Egress Scheduler provides shaping functions in the network processor. The Egress scheduler manages bandwidth on a per frame basis by determining the bandwidth a frame requires (that is, the number of bytes to be transmitted) and comparing this against the bandwidth permitted by the configuration of the frame's flow queue. The bandwidth used by the first frame affects when the Scheduler permits the transmission of the second frame of a flow queue. The Egress Scheduler characterizes flow queues with the parameters listed in *Table 6-2*. *Table 6-3* lists valid combinations of the parameters described in *Table 6-2*.

Table 6-2. Flow Queue Parameters

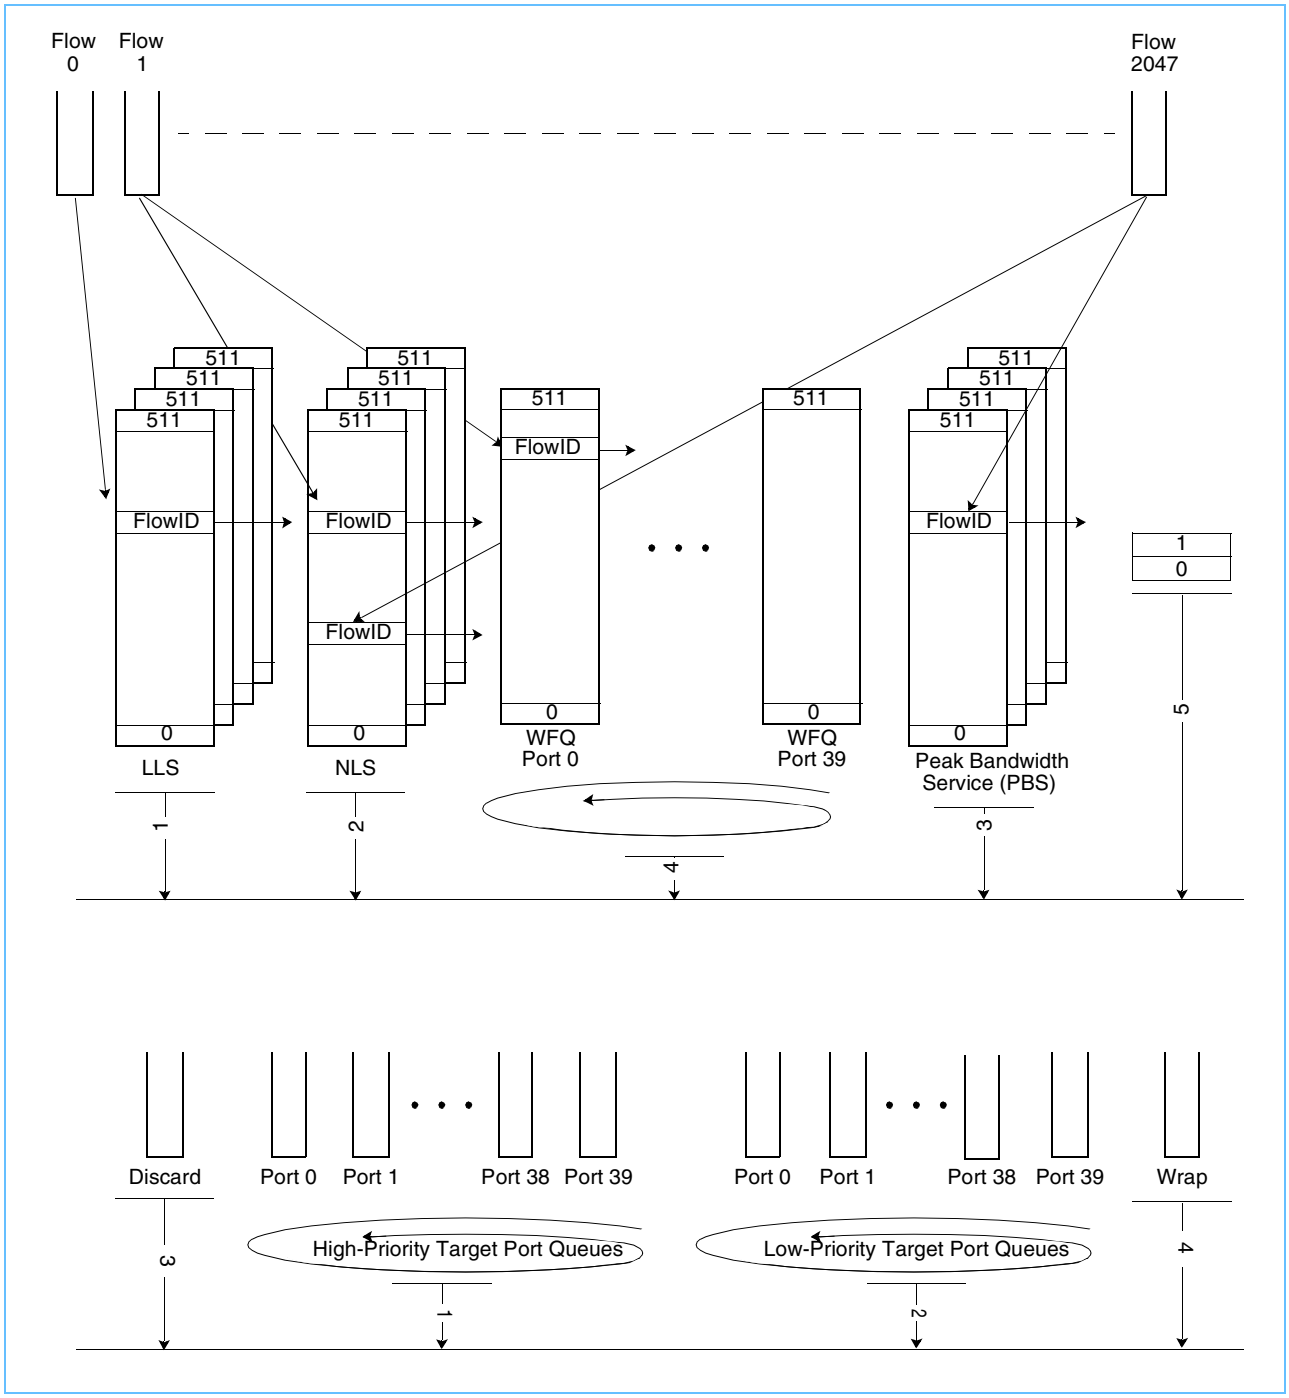
Parameter	Description
Low -latency sustainable bandwidth (LLS)	Provides guaranteed bandwidth with qualitative latency reduction. LLS has higher service priority than NLS. Flow queues connected to LLS have better latency characteristics than flow queues connected to NLS.
Normal-latency sustainable bandwidth (NLS)	Provides guaranteed bandwidth.
Peak bandwidth service (PBS)	Provides additional bandwidth on a best-effort basis.
Queue Weight	Allows the scheduler to assign available (that is, not assigned or currently not used by LLS and NLS) bandwidth to flow queues using best effort or PBS services. Assignment of different ratios of the available bandwidth is accomplished by assigning different queue weights to queues that share the same target port.

Table 6-3. Valid Combinations of Scheduler Parameters

QoS	LLS	NLS	Weight	PBS
Low Latency with Guaranteed BW Shaping	X			
Normal Latency with Guaranteed BW Shaping		X		
Best Effort			X	
Best Effort with Peak Rate			X	X
Normal Latency with Guaranteed BW Shaping and Best Effort		X	X	
Normal Latency with Guaranteed BW Shaping and Best Effort and Peak Rate		X	X	X

Figure 6-6 presents a graphical representation of the Egress Scheduler.

Figure 6-6. The Egress Scheduler



6.4.1 Egress Scheduler Components

The Egress Scheduler consists of the following components:

- Scheduling calendars
- 2047 flow queues (flow QCB addresses 1-2047) and 2047 associated scheduler control blocks (SCBs)
- Target port queues
- Discard Queue
- Wrap Queue

6.4.1.1 Scheduling Calendars

The Egress Scheduler selects a flow queue to service every scheduler_tick. The duration of a scheduler_tick is determined by the configuration of the DRAM Parameter register 11/$\overline{10}$ field (bit 6 only). When this register field is set to 0, a scheduler_tick is 150 ns. When the field is set to 1, a scheduler_tick is 165 ns.

There are three types of scheduling calendars used in the egress calendar design: time-based, weighted fair queuing (WFQ), and wrap.

Time-Based Calendars

The time-based calendars are used for guaranteed bandwidth (LLS or NLS) and for peak bandwidth service (PBS).

Weighted Fair Queuing Calendars

The WFQ calendars allocate available bandwidth to competing flows on a per-port basis. Available bandwidth is the bandwidth left over after the flows in the time-based calendars get their bandwidth. A WFQ calendar is selected for service only when no service is required by the time-based calendars and the target port queue does not exceed a programmable threshold. The use of this threshold is the method that assures the WFQ calendar dequeues frames to the target port at a rate equal to the port's available bandwidth.

Wrap Calendar

The wrap calendar is a 2-entry calendar for flows that use the wrap port.

Calendar Type Selection Algorithm

Selection among calendar types occurs each scheduler_tick based on the following priority list:

1. Time-based LLS
2. Time-based NLS
3. Time-based PBS
4. WFQ
5. Wrap

6.4.1.2 Flow Queues

There are 2047 flow queues (flow queue control block (QCB) addresses 1-2047) and scheduler control blocks. A flow QCB contains information about a single flow, as well as information that must be configured before the flow QCB can be used.

Configuring Sustainable Bandwidth (SSD)

The Sustained Service Rate (SSR) is defined as the minimum guaranteed bandwidth provided to the flow queue. It is implemented using either the LLS or NLS calendars. The following transform is used to convert the SSR from typical bandwidth specifications to scheduler step units (SSD field in the QCB):

SSD = (512 (bytes) / scheduler_tick (sec)) / Sustained_Service_Rate (bytes/sec)

The flow QCB SSD field is entered in exponential notation as X *16^{Y}, where X is the SSD.V field and Y is the SSD.E field . When an SSR is not specified, the flow QCB SSD field must be set to 0 during configuration.

Values of SSD that would cause the calendars to wrap should not be specified. Once the maximum frame size is known, SSD_{MAX} can be bound by:

$SSD_{MAX} \leq 1.07 * (10E + 9)$ / Maximum Frame Size (bytes)

An SSD value of 0 indicates that this flow queue has no defined guaranteed bandwidth component (SSR).

Configuring Flow QCB Flow Control Thresholds

When the number of bytes enqueued in the flow queue exceeds the Flow QCB Threshold (TH), the flow queue is congested. The flow control hardware uses this congestion indication to select the transmit probability. The following transform is used to specify this threshold:

TH.E	Threshold value (units in twin buffers)
0	TH.V * 2**6
1	TH.V * 2**9
2	TH.V * 2**12
3	TH.V * 2**15

TH.V and TH.E fields are components of the Flow Control Threshold field . A twin buffer contains approximately 106 bytes. A TH value of 0 disables threshold checking.

Configuring Best Effort Service (QD)

The Queue weight is used to distribute available bandwidth among queues assigned to a port. The remaining available bandwidth on a port is distributed among contending queues in proportion to the flow's queue weight.

The following transform is used to convert the Queue Weight into scheduler step units (QD field in the QCB):

QD = 1 / (Queue Weight)

A QD of 0 indicates that the flow queue has no best effort component.

Configuring Peak Best Effort Bandwidth (PSD)

Peak Service Rate is defined as the additional bandwidth that this flow queue is allowed to use (the difference between the guaranteed and the peak bandwidth). For example, if a service level agreement provided for a guaranteed bandwidth of 8 Mbps and a peak bandwidth of 10 Mbps, then the Peak Service Rate is 2 Mbps. The following transform is used to convert Peak Service Rate from typical bandwidth specifications to scheduler step units (PSD field in the QCB):

PSD = (512 (bytes) / scheduler_tick (sec)) / Peak_Service_Rate (bytes/sec)

The flow QCB PSD field is expressed in exponential notation as $X * 16^Y$, where X is the PSD.V field and Y is the PSD.E field. A PSD value of 0 indicates that this flow queue has no Peak Service Rate component.

Target Port

The destination target port (TP) ID.

Target Port Priority

The Target Port Priority (P) field selects either the low-latency sustainable bandwidth (LLS) or normal-latency sustainable bandwidth (NLS) calendar for the guaranteed bandwidth component of a flow queue. Values of 0 (high) and 1 (low) select the LLS or NLS calendar respectively.

During an enqueue to aTP queue, the P selects the correct queue. This field is also used in flow control.

Transmit Probability

Flow control uses the transmit probability field. The picocode flow control algorithms update this field periodically.

6.4.1.3 Target Port Queues

There are 82 target port queues, including 40 target ports with two priorities, a discard port, and a wrap port. The Scheduler dequeues frames from flow QCBs and places them into the target port queue that is designated by the flow QCB's Target Port (TP) and Priority (P) fields. A combination of a work-conserving round-robin and absolute priority selection services target port queues. The round-robin selects among the 40 media ports (target port IDs 0 - 39) within each priority class (high and low, as shown in *Figure 6-6* on page 174). The absolute priority makes a secondary selection based on the following priority list:

1. High Priority Target Port queues
2. Low Priority Target Port queues
3. Discard queue
4. Wrap queue

The following information must be configured for each target port queue.

Port Queue Threshold (Th_PQ)

When the number of bytes enqueued in the target port queue exceeds the port queue threshold, the corresponding weighted fair queueing (WFQ) calendar cannot be selected for service. This back pressure to the WFQ calendars assures that best effort traffic is not allowed to fill the target port queue ahead of frames dequeued from the low-latency sustainable bandwidth (LLS) and normal-latency sustainable bandwidth (NLS) calendars. The back pressure is the mechanism by which the target port bandwidth is reflected in the operation of the WFQ calendars.

The following transform is used to specify Th_PQ:

Th_PQ = Port_Queue_Threshold (bytes) / 106 (bytes)

When configuring this threshold, use a value larger than the maximum transmission unit (MTU) of the target port.

Port Queue + Flow Queue Threshold (Th_PQ+FQ)

This is the threshold for the total number of bytes in the target port queue plus the total number of bytes in all flow queues that are configured for this target port. When this threshold is exceeded by the value in the queue, the target port is congested. The flow control mechanisms use this congestion indication to select a transmit probability.

The following transform is used to specify Th_PQ+FQ:

Th_PQ+FQ = Port_Queue+Scheduler_Threshold (bytes) / 106 (bytes)

6.4.2 Configuring Flow Queues

Table 6-4 illustrates how to configure a flow QCB using the same set of Scheduler parameter combinations found in *Table 6-3: Valid Combinations of Scheduler Parameters* on page 173.

Table 6-4. Configure a Flow QCB

QoS	QCB.P	QCB.SD	QCB.PSD	QCB.QD
Low latency with Guaranteed BW shaping	0	≠ 0	0	0
Normal latency with Guaranteed BW shaping Best Effort	1	≠ 0	0	0
Best Effort	1	0	0	≠ 0
Best Effort with Peak Rate	1	0	≠ 0	≠ 0
Normal latency with Guaranteed BW shaping with Best Effort	1	≠ 0	0	≠ 0
Normal latency with Guaranteed BW shaping with Best Effort, and Peak Rate	1	≠ 0	≠ 0	≠ 0

6.4.2.1 Additional Configuration Notes

- Once the scheduler is enabled via the Memory Configuration Register, the picocode is unable to enqueue directly to a target port queue. To disable the Scheduler, the software system design must assure that the Scheduler is drained of all traffic. The control access bus (CAB) can examine all target port queue counts; when all counts are zero, the Scheduler is drained.
- A flow queue control block (QCB) must be configured for discards (TP = 41). A sustained service rate must be defined (SSD ≠ 0). A peak service rate and queue weight must not be specified (PSD = 0 and QD = 0).
- Two flow QCBs must be defined for wrap traffic. One must be defined for guided traffic (TP = 40), and one for frame traffic (TP = 42). For these QCBs, the peak service rate and sustained service rate must not be specified (PSD = 0 and SSD = 0). Queue weight must not be zero (QD ≠ 0).

7. Embedded Processor Complex

7.1 Overview

The Embedded Processor Complex (EPC) performs all processing functions for the NP4GS3. It provides and controls the programmability of the NP4GS3. In general, the EPC accepts data for processing from both the Ingress and Egress Enqueuer / Dequeuer / Schedulers. The EPC, under picocode control and with hardware-assisted coprocessors, determines what forwarding action is to be taken on the data. The data may be forwarded to its final destination, or may be discarded.

The EPC consists of the following components, as illustrated in *Figure 7-1* on page 184:

- Eight Dyadic Protocol Processor Units (DPPU)

  Each DPPU consists of two Core Language Processors (CLPs), nine shared coprocessors, one coprocessor data bus, one coprocessor command bus, and a shared memory pool.

  Each CLP contains one arithmetic and logic unit (ALU) and supports two picocode threads, so each DPPU has four threads (see *Section 7.1.1 Thread Types* on page 185 for more information). Although there are 32 independent threads, each CLP can execute the command of only one of its picocode threads, so at any instant only 16 threads are executing on all of the CLPs.

  The CLPs and coprocessors contain independent copies of each thread's registers and arrays. Most coprocessors perform specialized functions as described below, and can operate concurrently with each other and with the CLPs.

- Interrupts and Timers

  The NP4GS3 has four Interrupt Vectors. Each interrupt can be configured to initiate a dispatch to occur to one of the threads for processing.

  The device also has four timers that can be used to generate periodic interrupts.

- Instruction Memory

  NP4GS3A (R1.1): The Instruction Memory consists of eight embedded RAMs that are loaded during initialization and contain the picocode for forwarding frames and managing the system. The total size is 16 K instructions. The memory is 4-way interleaved with four RAMs for the first 8 K instructions and four RAMS for the remaining 8 K instructions. Each interleave provides four instruction words per access.

  NP4GS3B (R2.0): The Instruction Memory consists of eight embedded RAMs that are loaded during initialization and contain the picocode for forwarding frames and managing the system. The total size is 32 K instructions. The memory is 8-way interleaved, with each interleave providing four instruction words per access.

- Control Store Arbiter (CSA)

  The CSA controls access to the Control Store (CS) which allocates memory bandwidth among the threads of all the dyadic protocol processors. The CS is shared among the tree search engines and the picocode can directly access the CS through commands to the Tree Search Engine (TSE) coprocessor. The TSE coprocessor also accesses the CS during tree searches.

- Dispatch Unit

  The Dispatch Unit dequeues frame information from the Ingress-EDS and Egress-EDS queues. After dequeue, the Dispatch Unit reads part of the frame from the Ingress or Egress Data Store (DS) and places it into the DataPool. As soon as a thread becomes idle, the Dispatch Unit passes the frame (with appropriate control information) to the thread for processing.

  The Dispatch Unit also handles timers and interrupts by dispatching the work required for these to an available thread.

- Completion Unit (CU)

  The CU performs two functions:

  - It provides the interfaces between the EPC and the Ingress and Egress EDSs. Each EDS performs an enqueue action whereby a frame address, together with appropriate parameters, is queued in a transmission queue or a Dispatch Unit queue.
  - The CU guarantees frame sequence. Since multiple threads can process frames belonging to the same flow, the CU ensures that all frames are enqueued in the Ingress or Egress transmission queues in the proper order.

- Hardware Classifier (HC)

  The HC parses frame data that is dispatched to a thread. The results are used to precondition the state of a thread by initializing the thread's general purpose and coprocessor scalar registers and a starting instruction address for the CLP.

  Parsing results indicate the type of Layer 2 encapsulation, as well as some information about the Layer 3 packet. Recognizable Layer 2 encapsulations include PPP, 802.3, DIX V2, LLC, SNAP header, and VLAN tagging. Reportable Layer 3 information includes IP and IPX network protocols, five programmable network protocols, the detection of IP option fields, and transport protocols (UDP, TCP) for IP.

- Ingress and Egress Data Store Interface and Arbiter

  Each thread has access to the Ingress and Egress Data Store through a Data Store coprocessor. Read access is provided when reading "more Data" and write access is provided when writing back the contents of the Shared Memory Pool (SMP) to the Data Store. One arbiter is required for each data store since only one thread at a time can access either data store.

- Control Access Bus (CAB) Arbiter

  Each thread has access to the CAB, which permits access to all memory and registers in the network processor. The CAB Arbiter arbitrates among the threads for access to the CAB.

- Debugging and Single-Step Control

  The CAB enables the GFH thread to control each thread on the device for debugging purposes. For example, the CAB can be used by the GFH thread to run a selected thread in single-step execution mode. (See *Section 12. Debug Facilities* on page 435 for more information.)

- Policy Manager

  The Policy Manager is a hardware assist of the EPC that performs policy management on up to 1 K ingress flows. It supports four management algorithms. The two algorithm pairs are “Single Rate Three Color Marker” and “Two Rate Three Color Marker,” both of which can be operated in color-blind or color-aware mode. The algorithms are specified in IETF RFCs 2697 and 2698, available at http://www.ietf.org.

- Counter Manager

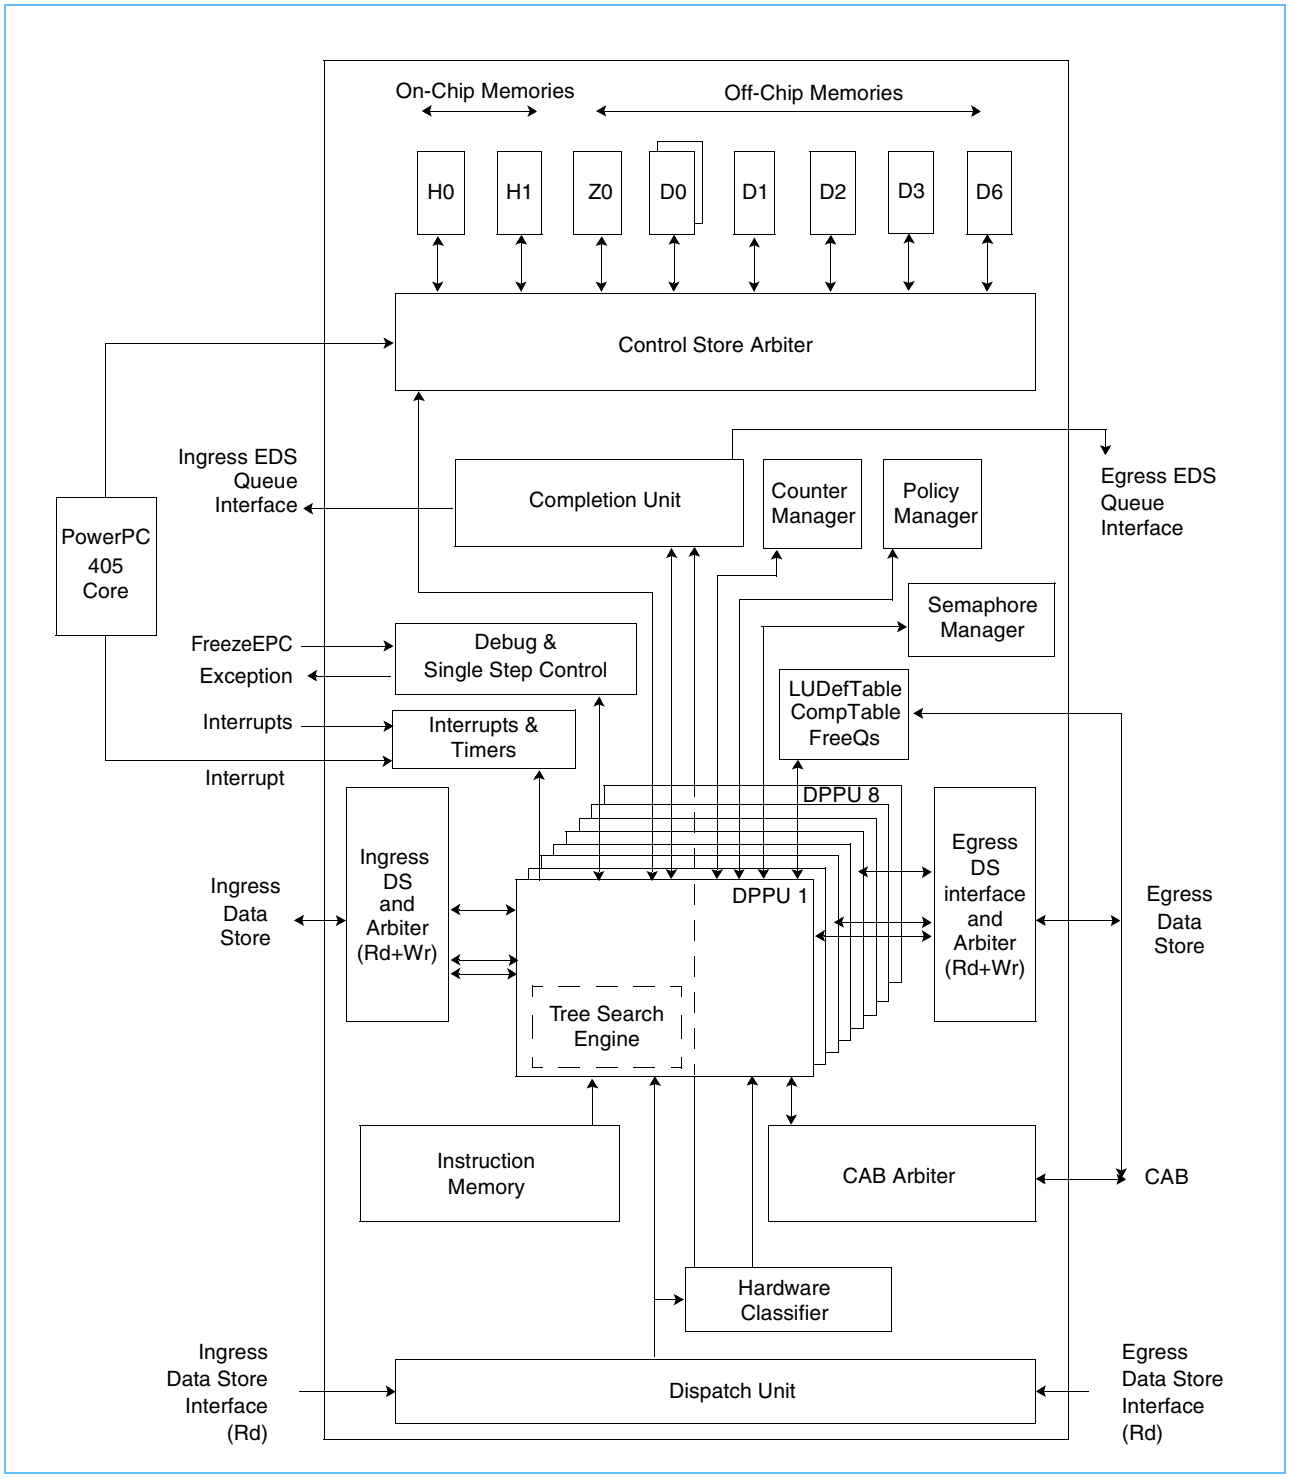
  The Counter Manager is a hardware assist engine used by the EPC to manage counters defined by the picocode for statistics, flow control, and policy management. The Counter Manager is responsible for counter updates, reads, clears, and writes. The Counter Manager's interface to the Counter coprocessor provides picocode access to these functions.

- Semaphore Manager

  The Semaphore Manager assists in controlling access to shared resources, such as tables and control structures, through the use of semaphores. It grants semaphores either in dispatch order (ordered semaphores) or in request order (unordered semaphores).

- LuDefTable, CompTable, and Free Queues are tables and queues for use by the tree search engine. For more information, see *Section 8.2.5.1 The LUDefTable* on page 311.

Figure 7-1. Embedded Processor Complex Block Diagram



7.1.1 Thread Types

The EPC has 32 threads that can simultaneously process 32 frames. A thread has a unique set of General Purpose, Scalar, and Array registers, but shares execution resources in the CLP with another thread and execution resources in the coprocessors with three other threads. Each CLP within a DPPU can run two threads, making four threads per DPPU, or 32 total. The first DPPU contains the GFH, GTH, and the PPC threads and the other seven DPPUs contain the GDH threads. These five types of threads are described in the following list:

- General Data Handler (GDH)

  There are 28 GDH threads. GDHs are used for forwarding frames.

- Guided Frame Handler (GFH)

  There is one GFH thread available in the EPC. A guided frame can only be processed by the GFH thread, but the GFH can be configured to process data frames like a GDH thread. The GFH executes guided frame-related picocode, runs device management related picocode, and exchanges control information with a control point function or a remote network processor. When there is no such task to perform and the option is enabled, the GFH may execute frame forwarding-related picocode.

- General Table Handler (GTH)

  There is one GTH thread available in the EPC. The GTH executes tree management commands not available to other threads. The GTH performs actions including hardware assist to perform tree inserts, tree deletes, tree aging, and rope management. The GTH can process data frames like a GDH when there are no tree management functions to perform.

- General PowerPC Handler Request (GPH-Req)

  There is one GPH-Req thread available in the EPC. The GPH-Req thread processes frames bound to the embedded PowerPC. Work for this thread is the result of a re-enqueue action from another thread in the EPC to the GPQ queue. The GPH-Req thread moves data bound for the PowerPC to the PowerPC's Mailbox (a memory area) and then notifies the PowerPC that it has data to process. See *Section 10.8 Mailbox Communications and DRAM Interface Macro* on page 382 for more information.

- General PowerPC Handler Response (GPH-Resp)

  There is one GPH-Resp thread available in the EPC. The GPH-Resp thread processes responses from the embedded PowerPC. Work for this thread is dispatched due to an interrupt initiated by the PowerPC and does not use Dispatch Unit memory. All the information used by this thread is found in the embedded PowerPC's Mailbox. See *Section 10.8 Mailbox Communications and DRAM Interface Macro* on page 382 for more information.

7.2 Dyadic Protocol Processor Unit (DPPU)

This section describes the basic functionality of the DPPU. Two aspects of the DPPU are discussed in detail in separate sections: *Section 7.3 beginning on page 194* discusses the operational codes (opcodes) for the Core Language Processors (CLPs), and *Section 7.4 beginning on page 223* cover's the DPPU's coprocessors.

Each DPPU consists of the following functional blocks, as illustrated in *Figure 7-2* (for NP4GS3A (R1.1)) and *Figure 7-3* (for NP4GS3B (R2.0)).

Two Core Language Processors (CLPs)

- Eight coprocessors
- A coprocessor data bus
- A coprocessor command bus (the Coprocessor Databus and Coprocessor Execution interfaces)
- A 4-KB shared memory pool (1 KB per thread)

Each CLP supports two threads, so each DPPU has four threads which execute the picocode that is used to forward frames, update tables, and maintain the network processor.

Each DPPU interfaces with the following functional blocks of the EPC:

- Instruction Memory
- Dispatch Unit
- Control Store Arbiter (CSA)
- Completion Unit (CU)
- Hardware Classifier
- Interface and arbiter to the Ingress and Egress Data Stores
- Control Access Bus (CAB) Arbiter
- Debugging facilities
- Counter Manager
- Policy Manager
- LuDefTable Queue
- Comp Free Queue
- Semaphore Manager (NP4GS3B (R2.0))

Figure 7-2. Dyadic Protocol Processor Unit Functional Blocks (NP4GS3A (R1.1))

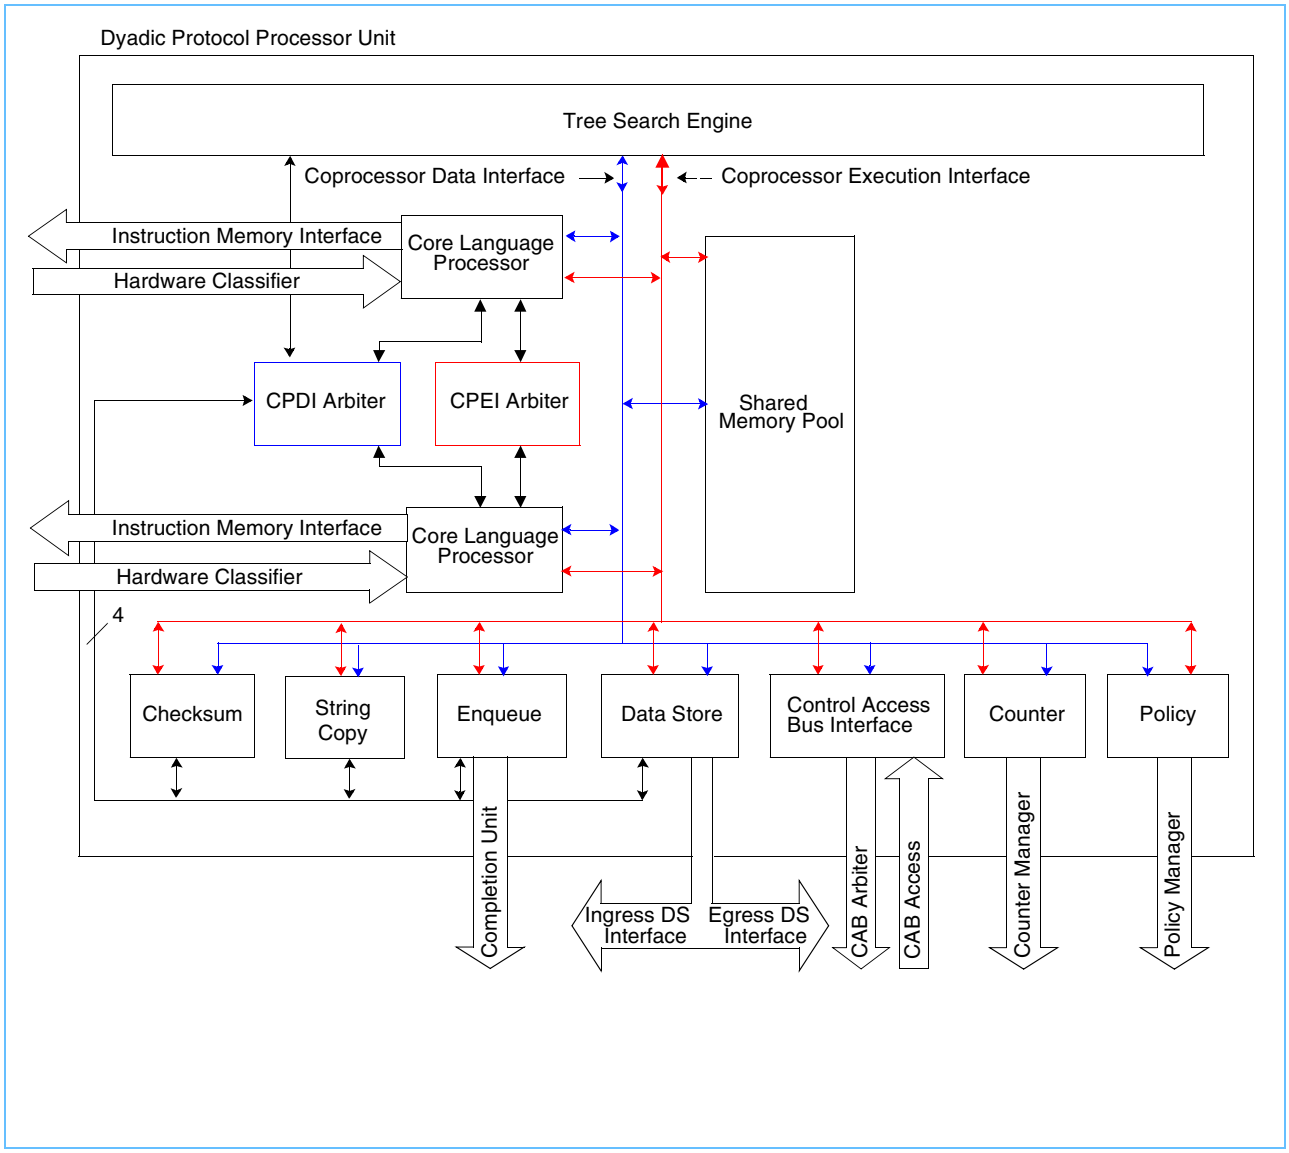


Figure 7-3. Dyadic Protocol Processor Unit Functional Blocks (NP4GS3B (R2.0))

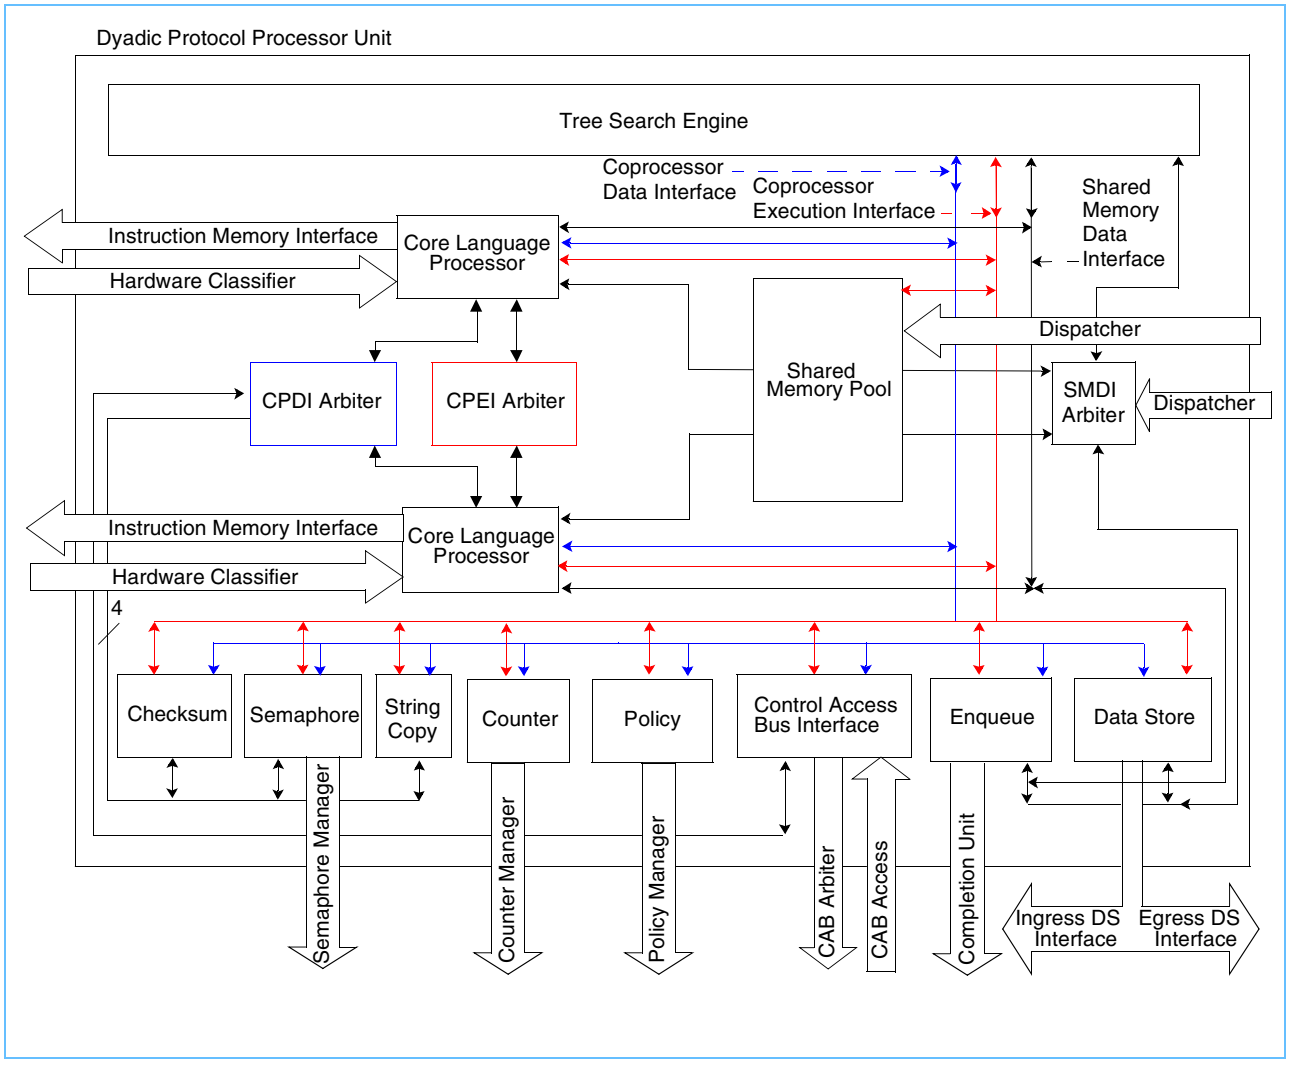


7.2.1 Core Language Processor (CLP)

Each DPPU contains two CLPs. The CLP executes the EPC's core instruction set and controls thread swapping and instruction fetching. Each CLP is a 32-bit picoprocessor consisting of:

- 16 32-bit or 32 16-bit General Purpose Registers (GPRs) per thread. (For more information, see *Table 7-1: Core Language Processor Address Map on page 190.*)
- A one-cycle ALU supporting an instruction set that includes:
  - Binary addition and subtraction
  - Bit-wise logical AND, OR, and NOT
  - Compare
  - Count leading zeros
  - Shift left and right Logical
  - Shift right arithmetic
  - Rotate Left and Right

  - Bit manipulation commands: set, clear, test, and flip
  - GPR transfer of Halfword to Halfword, Word to Word, and Halfword to Word with and without sign extensions
  - All instructions can be coded to run conditionally. This eliminates the need for traditional branch-and-test coding techniques, which improves performance and reduces the size of the code. All arithmetic and logical instructions can be coded to execute without setting ALU status flags.

- Management for handling two threads with zero overhead for context switching

- Read-only scalar registers that provide access to the following information:
  - Interrupt vectors
  - Timestamps
  - Output of a pseudo random number generator
  - Picoprocessor status
  - Work queue status (such as the ingress and egress data queues)
  - Configurable identifiers (such as the blade identification)

  For more information, see *Table 7-1: Core Language Processor Address Map on page 190*.

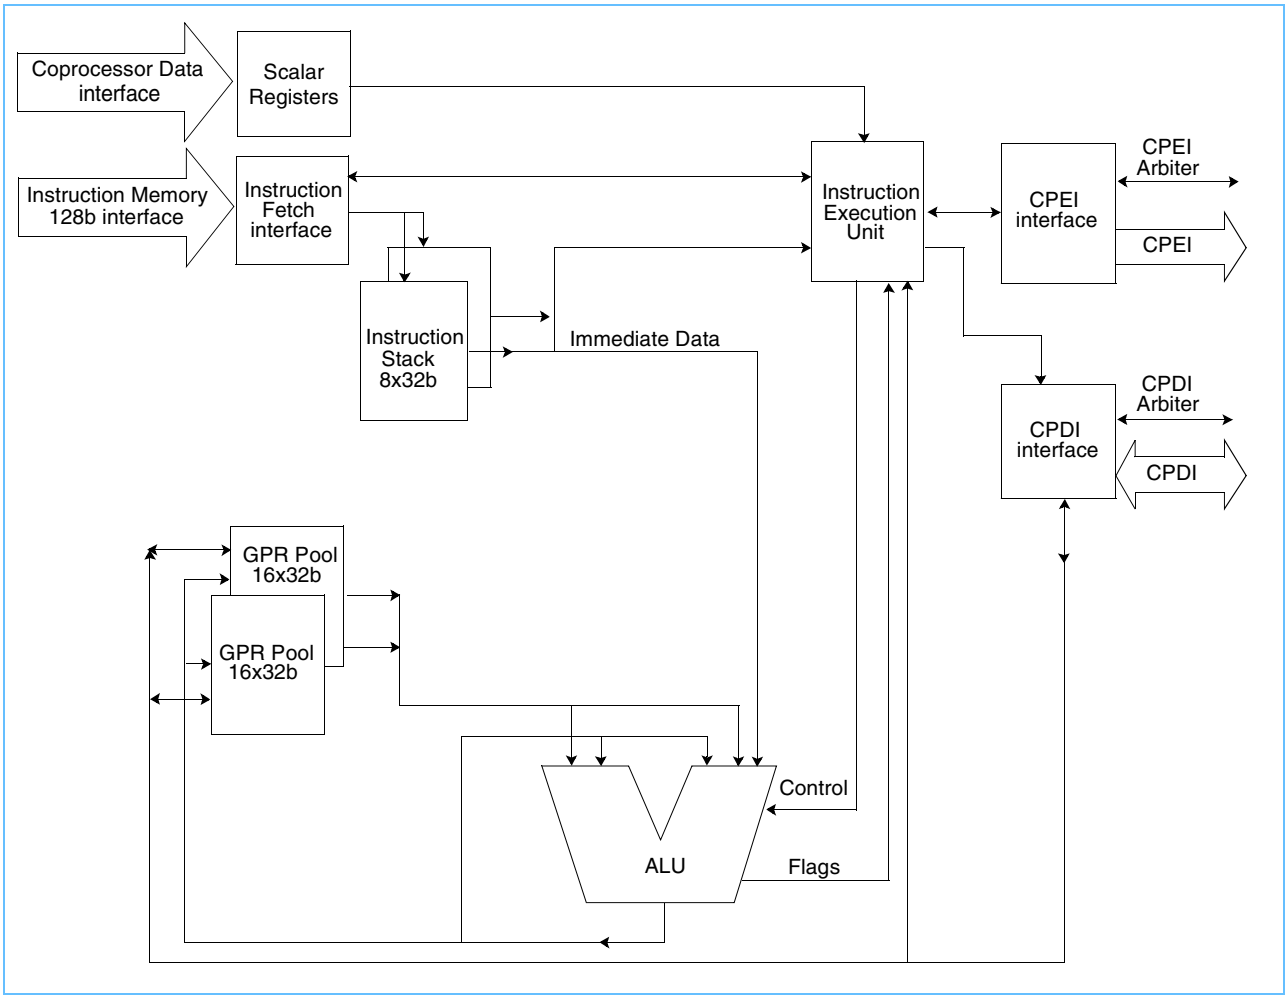
- 16-word instruction prefetch shared by each thread

- Instruction Execution unit that executes branch instructions, instruction fetch, and coprocessor access

- Coprocessor Data Interface (CPDI) with the following features:
  - Access from any byte, halfword, or word of a GPR to an array, or from an array to a GPR
  - Access to coprocessor scalar registers
  - Various sign, zero, and one extension formats
  - Quadword transfers within the coprocessor arrays
  - Quadword reset to zero of coprocessor arrays (NP4GS3B (R2.0))

- Coprocessor Execution Interface (CPEI) with the following features:
  - Synchronous or asynchronous coprocessor operation
  - Multiple coprocessor synchronization
  - Synchronization and Branch-on-Coprocessor Return Code

Figure 7-4. Core Language Processor



7.2.1.1 Core Language Processor Address Map

Table 7-1. Core Language Processor Address Map (Page 1 of 3)

Name	Register (Array)[1] Number	Size (Bits)	Access	Description
PC	x'00'	16	R	Program Counter. Address of the next instruction to be executed.
ALUStatus	x'01'	4	R	The current ALU status flags: 3 Zero 2 Carry 1 Sign 0 Overflow
LinkReg	x'02'	16	R/W	Link Register. Return address for the most recent subroutine

1. A number in parentheses is the array number for this coprocessor. Each array has a register number and an array number.

Table 7-1. Core Language Processor Address Map (Page 2 of 3)

Name	Register (Array)[1] Number	Size (Bits)	Access	Description
CoPStatus	x‘03’	10	R	Indicates whether the coprocessor is busy or idle. A coprocessor that is Busy will stall the CLP when the coprocessor command was executed synchronously or a wait command was issued for the coprocessor. 1 Coprocessor is Busy 0 Coprocessor is Idle
CoPRtnCode	x‘04’	10	R	The definition of OK/KO is defined by the coprocessor. 1 OK 0 Not OK
ThreadNum	x‘05’	5	R	The thread number (0..31)
Stack_link_ptr	x’06’	4	R	The current pointer value into the CLP link stack (NP4GS3B (R2.0))
TimeStamp	x‘80’	32	R	Free-running, 1 ms timer
RandomNum	x‘81’	32	R	Random number for programmer’s use
IntVector0	x‘83’	32	R	Read-Only copy of Interrupt Vector 0. Reading this register has no effect on the actual Interrupt Vector 0.
IntVector1	x‘84’	32	R	Read-Only copy of Interrupt Vector 1. Reading this register has no effect on the actual Interrupt Vector 1.
IntVector2	x‘85’	32	R	Read-Only copy of Interrupt Vector 2. Reading this register has no effect on the actual Interrupt Vector 2.
IntVector3	x‘86’	32	R	Read-Only copy of Interrupt Vector 3. Reading this register has no effect on the actual Interrupt Vector 3.
IdleThreads	x‘87’	32	R	Indicates that a thread is enabled and idle
QValid	x‘88’	32	R	Indicates status of the queues (valid or invalid).
My_TB	x‘89’	6	R	My Target Blade. The blade number of the blade in which this network processor is currently residing (see *Section 13.13.9 My Target Blade Address Register (My_TB)* on page 468)
SW_Defined_A	x‘8A’	32	R	Software-Defined Register
SW_Defined_B	x‘8B’	32	R	Software-Defined Register
SW_Defined_C	x‘8C’	32	R	Software-Defined Register
Version_ID	x‘8F’	32	R	Contains the version number of the hardware.
GPRW0	x‘C0’	32	R	General Purpose Register W0
GPRW2	x‘C1’	32	R	General Purpose Register W2
GPRW4	x‘C2’	32	R	General Purpose Register W4
GPRW6	x‘C3’	32	R	General Purpose Register W6
GPRW8	x‘C4’	32	R	General Purpose Register W8
GPRW10	x‘C5’	32	R	General Purpose Register W10
GPRW12	x‘C6’	32	R	General Purpose Register W12
GPRW14	x‘C7’	32	R	General Purpose Register W14
GPRW16	x‘C8’	32	R	General Purpose Register W16
GPRW18	x‘C9’	32	R	General Purpose Register W18

1. A number in parentheses is the array number for this coprocessor. Each array has a register number and an array number.

Table 7-1. Core Language Processor Address Map (Page 3 of 3)

Name	Register (Array)[1] Number	Size (Bits)	Access	Description
GPRW20	x‘CA’	32	R	General Purpose Register W20
GPRW22	x‘CB’	32	R	General Purpose Register W22
GPRW24	x‘CC’	32	R	General Purpose Register W24
GPRW26	x‘CD’	32	R	General Purpose Register W26
GPRW28	x‘CE’	32	R	General Purpose Register W28
GPRW30	x‘CF’	32	R	General Purpose Register W30
PgramStack0	x‘FC’ (0)	128	R/W	Entries in the Program Stack (used by the CLP hardware to build instruction address stacks for the branch and link commands)
PgramStack1	x‘FD’ (1)	128	R/W	Entries in the Program Stack (used by the CLP hardware to build instruction address stacks for the branch and link commands)

1. A number in parentheses is the array number for this coprocessor. Each array has a register number and an array number.

7.2.2 CLP Opcode Formats

The core instructions (opcodes) of the CLP, their formats, and their definitions are discussed in detail in *Section 7.3 beginning on page 194*.

7.2.3 DPPU Coprocessors

All data processing occurs in the eight DPPU coprocessors. They are discussed in detail in *Section 7.4 beginning on page 223*.

7.2.4 Shared Memory Pool

The 4-Kb shared memory pool is used by all threads running in the DPPU. Each thread uses 1 Kb and is subdivided into the following areas:

Table 7-2. Shared Memory Pool

Quadword Address	Owning Coprocessor	Array
0-2	Enqueue	FCB Page 1A
3	Data Store	Configuration Quadword
4-6	Enqueue	FCB Page 1B
7	CLP	Stack 0
8-10	Enqueue	FCB Page 2
11	CLP	Stack 1
12-15	Data Store	Scratch Memory 0
16-23	Data Store	DataPool
24-31	Data Store	Scratch Memory 1
32-47	TSE	Tree Search Results Area 0
40-47	TSE	Tree Search Results Area 1
48-63	TSE	Tree Search Results Area 2
56-63	TSE	Tree Search Results Area 3

7.3 CLP Opcode Formats

This section describes the core instructions (opcodes) of the CLP, their formats, and their definitions. CLP opcodes fall into four categories: control opcodes, ALU opcodes, data movement opcodes, and coprocessor execution opcodes. Shaded areas of the opcode show which bits uniquely identify the opcode.

7.3.1 Control Opcodes

Most control opcodes have field a condition field (Cond) that indicates under what condition of the ALU flags Z (zero), C (carry), N (negative), and V (overflow) this command should be executed. The CLP supports 15 different signed and unsigned conditions.

Table 7-3. Condition Codes (Cond Field)

Value	ALU Flag Comparison	Meaning
0000	Z = 1	equal or zero
0001	Z = 0	not equal or not zero
0010	C = 1	carry set
0011	C = 1 AND Z = 0	unsigned higher
0100	C = 0 OR Z = 1	unsigned lower or equal
0101	C = 0	unsigned lower
0110	-	Reserved
0111	Don't Care	Always
1000	N = 0	signed positive
1001	S = 1	signed negative
1010	N = V	signed greater or equal
1011	Z = 0 AND N = V	signed greater than
1100	Z = 1 OR (N/ = V)	signed less than or equal
1101	N/ = V	signed less than
1110	V = 1	overflow
1111	V = 0	no overflow

Type	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
nop	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
exit	0	0	0	1	0	0	0	0	Cond				0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
branch and Link	0	0	0	1	1	h	1	1	Cond				Rt				target16															
return	0	0	0	1	1	0	0	0	Cond				0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
branch register	0	0	0	1	1	h	0	0	Cond				Rt				0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
branch pc relative	0	0	0	1	1	0	1	0	Cond				0	0	0	0	disp16															
branch reg+off	0	0	0	1	1	0	0	1	Cond				Rt				target16															

7.3.1.1 Nop Opcode

The nop opcode executes one cycle of time and does not change any state within the processor.

7.3.1.2 Exit Opcode

The exit opcode terminates the current instruction stream. The CLP will be put into an idle state and made available for a new dispatch. The exit command is executed conditionally, and if the condition is not true, it will be equivalent to a nop opcode.

pseudocode:

```
IF (cond) THEN
    clp_state_machine <- idle
ELSE
     nop
END IF
```

7.3.1.3 Branch and Link Opcode

The branch and link opcode performs a conditional branch, adds one to the value of the current program counter, and places it onto the program stack. Opcode fields Rt, h, and target16 determine the destination of the branch. If Rt is in the range of 1 - 15, it is the word address of a GPR register, the contents of which are used as the base of the branch destination. If Rt is 0, the base of the branch destination will be 0x'0000'. The h field indicates which half of the GPR register is used as the base address. An h = 0 indicates the even half of the GPR register (high half of the GPR) and h = 1 indicates the odd half. The target16 field is added to the base to form the complete branch destination. If the LinkPtr register indicates that the Branch and Link will overflow the 16-entry program stack, a stack error occurs.

pseudocode:

```
IF (cond) THEN

     -- put IA+1 onto the program stack
     IF (LinkPtr=EndOfStack) THEN
          StackErr <- 1
     ELSE
           ProgramStack(LinkPtr+1) <- PC + 1
     END IF

     -- load the IA with the branch target
     IF (Rt=0) THEN
          PC <- target16
     ELSIF (h=0) THEN
          PC <- GPR(Rt)(31:16) + target16
     ELSE
          PC <- GPR(Rt)(15:0) + target16
     END IF

ELSE
     nop
END IF
```

7.3.1.4 Return Opcode

The return opcode performs a conditional branch with the branch destination being the top of the program stack. If the LinkPtr register indicates that the stack is empty, a stack error occurs.

pseudocode:

```
IF (cond) THEN
     IF (LinkPtr=EmptyStack) THEN
          StackErr <- 1
     ELSE
           PC <- ProgramStack(LinkPtr)
     END IF
ELSE
   nop
END IF
```

7.3.1.5 Branch Register Opcode

The branch and link opcode performs a conditional branch. Opcode fields Rt and h determine the destination of the branch. The Rt field is the word address of a GPR register of which the contents will be used as the branch destination. The h field indicates which half of the GPR register will be used. An h = 0 indicates the even half of the GPR register (high half of the GPR), and h = 1 indicates the odd half.

pseudocode:

```
IF (cond) THEN
     IF (h=0) THEN
          PC <- GPR(Rt)(31:16) + target16
     ELSE
          PC <- GPR(Rt)(15:0) + target16
     END IF
ELSE
     nop
END IF
```

7.3.1.6 Branch PC Relative Opcode

The branch PC relative opcode performs a conditional branch. Opcode fields PC and disp16 determine the destination of the branch. The contents of the PC field are used as the base of the branch destination. The disp16 field will be added to the base to form the complete branch destination.

pseudocode:

```
IF (cond) THEN
     PC <- PC + disp16
    ELSE
     nop
END IF
```

7.3.1.7 Branch Reg+Off Opcode

The branch register plus offset opcode will perform a conditional branch. The Opcode fields Rt and target16 determine the destination of the branch. If Rt is in the range of 1 - 15, it is the word address of a GPR register of which the contents of the high halfword (or even half) are used as the base of the branch destination. If Rt is 0, the base of the branch destination is x'0000'. The target16 field is added to the base to form the complete branch destination.

pseudocode:

```
IF (cond) THEN
     IF (Rt=0) THEN
          PC <- target16
      ELSE
          PC <- GPR(Rt)(31:16) + target16
     END IF
ELSE
     nop
END IF
```

7.3.2 Data Movement Opcodes

The data movement opcodes are used to transfer data to and from the coprocessor's scalar registers and arrays. The opcodes support 23 options of direction, size, extension, and fill, represented by the ot5 field. Data movement opcodes access the processor data interface (PDI).

Figure 7-5. ot5 Field Definition: Loading Halfword/Word GPRs from a Halfword/Word Array

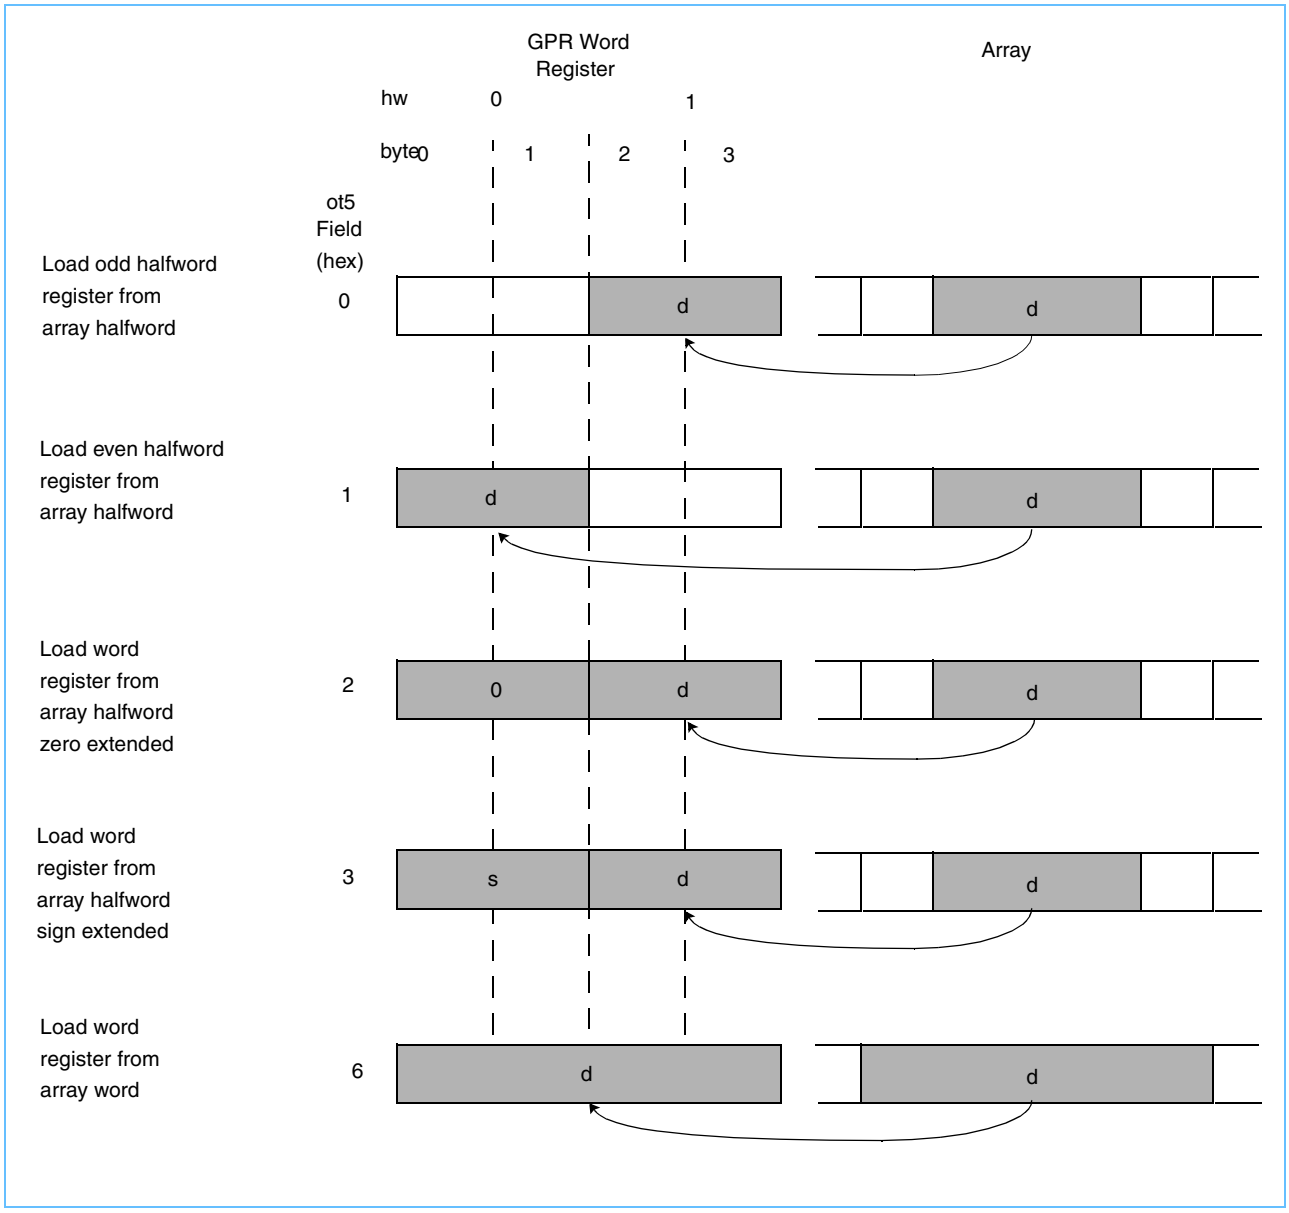


Figure 7-6. ot5 Field Definition: Loading GPR Byte From Array Byte

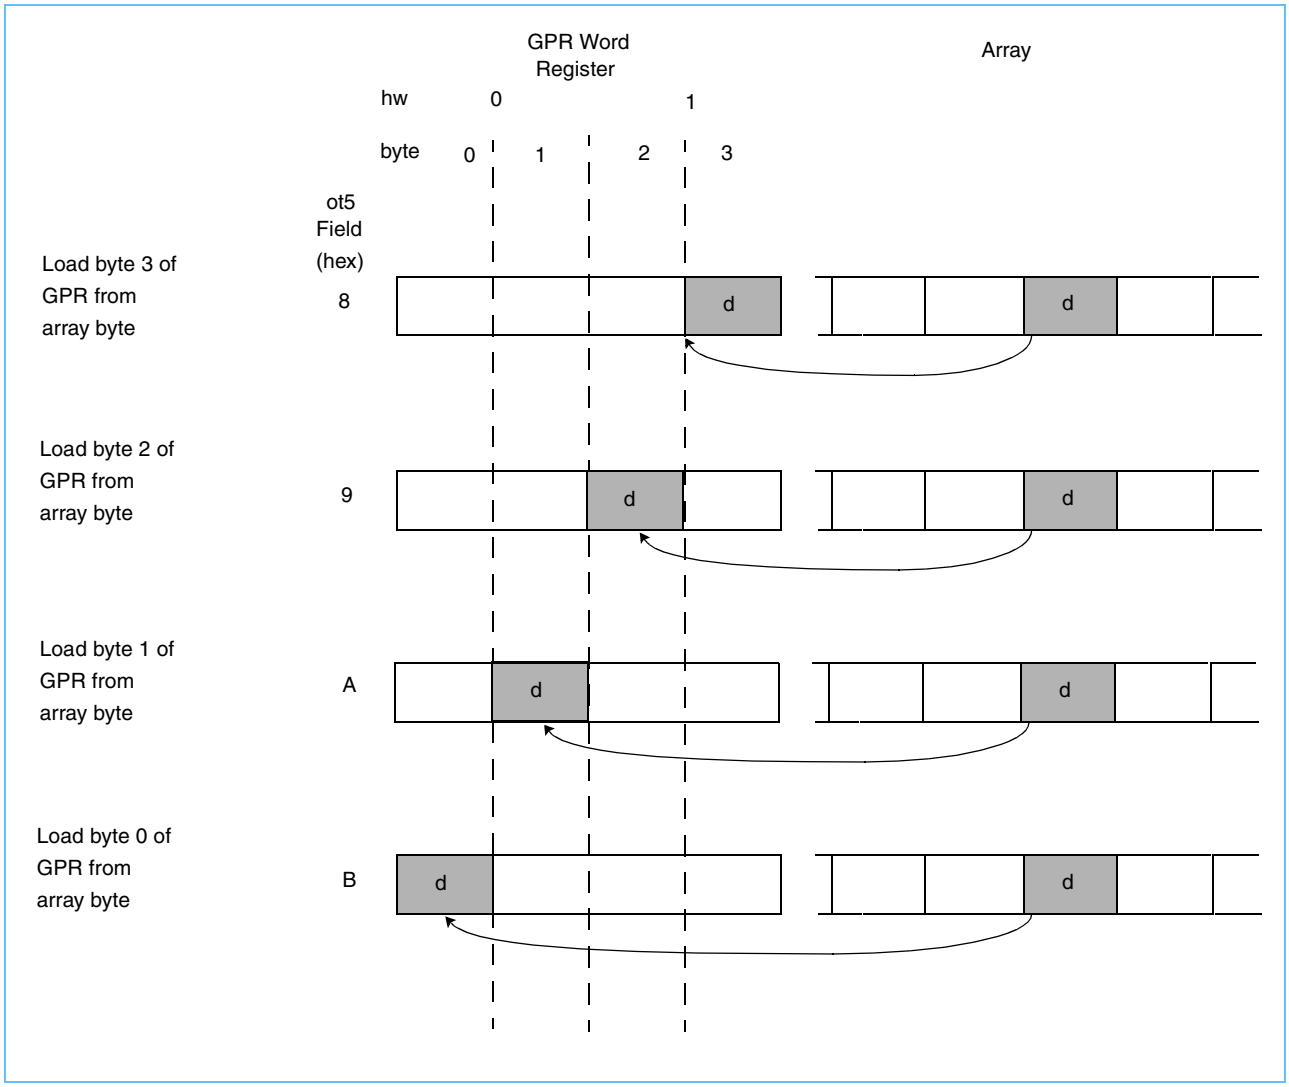

Figure 7-7. ot5 Field Definition: Loading GPR Halfword/Word from Array Byte

zero array	1	1	0	0	0	0	size		Cond				Boffset				x	0	0	0	C#				Ca		1	1	QWoffs			

7.3.2.1 Memory Indirect Opcode

The memory indirect opcode transfers data between a GPR and a coprocessor array via a logical address in which the base offset into the array is contained in a GPR. The logical address consists of a coprocessor number, coprocessor array, base address, and an offset. The C# field indicates the coprocessor which will be accessed. The Ca field indicates which array of the coprocessor will be accessed. The offset into the array is the contents of GPR, indicated by Ra as a base plus the six bits of immediate offset, off6. Ra is a half-word address in the range of 0 - 7. The x indicates whether or not the transaction will be in cell header skip mode. The memory indirect opcode is executed conditionally if the ALU flags meet the condition represented by the Cond field. The word address of the GPR register used to transfer or receive data from the array is indicated by the field R. The actual direction, size, extension format, and location of GPR bytes affected are indicated by the ot5 field.

pseudocode:

```
IF (cond) THEN
    addr.coprocessor number <= C#
    addr.coprocessor array     <= Ca
    addr.array offset                <= GPR(Ra)+off6
    addr.x_mode                     <= x

    IF (ot5 = load) THEN
       GPR(R,ot5) <= array(addr)
    ELSE
       array(addr) <= GPR(R,ot5)
    END IF;

END IF
```

7.3.2.2 Memory Address Indirect Opcode

The memory address indirect opcode transfers data between a GPR and a coprocessor data entity (scalar or array) by mapping the coprocessor logical address into the base address held in the GPR indicated by Ra. Since not all of the coprocessors have arrays, maximum size arrays, or the maximum number of scalars, the address map will have many gaps. Data access via this method is the same as access via the more logic-based method. The final address is formed by the contents of GPR indicated by Ra plus off8 (eight bits). Ra is a half-word address in the range of 0 - 7. The x indicates whether or not the transaction will be in cell header skip mode.

The memory address indirect opcode is executed conditionally if the ALU flags meet the condition represented by the Cond field. The word address of the GPR register used to transfer or receive data from the array is indicated by the field R. The actual direction, size, extension format, and location of GPR bytes affected are indicated by the ot5 field.

pseudocode:

```
IF (cond) THEN
    address <= GPR(Ra) + off8

    addr.array_notScalar         <= address(14)
    addr.coprocessor number <= address(13:10)
    addr.coprocessor array     <= address(9:8) (if an array access)
    addr.scalar address           <= address(7:0) (if a scalar access)
    addr.array offset                <= address(7:0) (if an array access)
    addr.x_mode                     <= x

    IF (ot5 = load) THEN
       IF (addr.array_notScalar='1') THEN
         GPR(R,ot5) <= array(addr)
       ELSE
         GPR(R,ot5) <= scalar(addr)
       END IF;
    ELSE
       IF (addr.array_notScalar='1') THEN
          array(addr) <= GPR(R,ot5)
       ELSE
         scalar(addr) <= GPR(R,ot5)
       END IF;
     END IF;
END IF
```

7.3.2.3 Memory Direct Opcode

The memory direct opcode transfers data between a GPR and a coprocessor array via a logical address that is specified in the immediate portion of the opcode. The logical address consists of a coprocessor number, coprocessor array, and an offset. The C# field indicates the coprocessor that is accessed. The Ca field indicates which array of the coprocessor is accessed. The offset is the six bits of immediate field, off6. The x indicates whether or not the transaction will be in cell header skip mode. The memory direct opcode is executed conditionally if the ALU flags meet the condition represented by the Cond field. The word address of the GPR register used to transfer or receive data from the array is indicated by the R field. The actual direction, size, extension format, and location of GPR bytes affected are indicated by the ot5 field.

pseudocode:

```
IF (cond) THEN
    addr.coprocessor number <= C#
    addr.coprocessor array     <= Ca
    addr.array offset                <= off6
    addr.x_mode                     <= x

    IF (ot5 = load) THEN
       GPR(R,ot5) <= array(addr)
    ELSE
       array(addr) <= GPR(R,ot5)
    END IF;

END IF
```

7.3.2.4 Scalar Access Opcode

The scalar access opcode transfers data between a GPR and a scalar register via a logical address that consists of a coprocessor number and a scalar register number. The C# field indicates the coprocessor that is accessed. The scalar register number is indicated by the Cr field. The scalar access opcode is executed conditionally if the ALU flags meet the condition represented by the Cond field. The word address of the GPR register used to transfer or receive data from the scalar register is indicated by the R field. The actual direction, size, extension format, and location of GPR bytes affected are indicated by the ot5 field.

pseudocode:

```
IF (cond) THEN
    addr.coprocessor number <= C#
    addr.scalar number           <= Ca

    IF (ot5 = load) THEN
       GPR(R,ot5) <= scalar(addr)
    ELSE
      scalar(addr) <= GPR(R,ot5)
    END IF;
END IF
```

7.3.2.5 Scalar Immediate Opcode

The scalar immediate opcode writes immediate data to a scalar register via a logical address that is completely specified in the immediate portion of the opcode. The logical address consists of a coprocessor number and a coprocessor register number. The C# field indicates the coprocessor that is accessed. The Cr field indicates the scalar register number. The scalar access opcode is executed conditionally if the ALU flags meet the condition represented by the Cond field. The data to be written is the Imm16 field.

pseudocode:

```
IF (cond) THEN
    addr.coprocessor number    <= C#
    addr.scalar register number <= Ca
    scalar(addr) <= Imm16

END IF
```

7.3.2.6 Transfer Quadword Opcode

The transfer quadword opcode transfers quadword data from one array location to another using one instruction. The source quadword is identified by the C#s (coprocessor number), Cas (source array number), and QWoffs (quadword offset into the array). The destination quadword is identified by the C#d, Cad, and QWoffd.This transfer is only valid on quadword boundaries.

pseudocode:

```
saddr.coprocessor number <= C#s
saddr.array number             <= Cas
saddr.quadword offset         <= QWoffs
daddr.coprocessor number <= C#d
daddr.array number             <= Cad
daddr.quadword offset         <= QWoffd

array(daddr) <= array(saddr)
```

7.3.2.7 Zero Array Opcode (NP4GS3B (R2.0) Only)

The zero array opcode zeroes out a portion of an array with one instruction. The size of the zeroed-out portion can be a byte, halfword, word, or quadword. Quadword access must be on quadword address boundaries. Accesses to a byte, halfword, or word can begin on any byte boundary and will have the same characteristics as any GPR-based write to the array. For example, if the array is defined to wrap from the end to the beginning, the zero array command wraps from the end of the array to the beginning. The C# field indicates the coprocessor that will be accessed. The Ca field indicates which array of the coprocessor is accessed. The QWoff is the quadword offset into the array, and the Boff is the byte offset into the array. The x indicates whether or not the transaction is in cell header skip mode. The opcode is executed conditionally if the ALU flags meet the condition represented by the Cond field. The actual size of the access is defined by the size field (byte = 00, halfword = 01, word = 10, quadword = 11). For quadword accesses Boff should equal 0x0.

pseudocode:

```
IF (cond) THEN
  addr.coprocessor number <= C#
  addr.array number             <= Ca
  addr.quadword offset         <= QWoff
  addr.byte offset                   <= Boff

  IF size = 00 THEN
     array(addr) <= 0x00
  IF size = 01 THEN
     array(addr : addr+1) <= 0x0000
  IF size = 10 THEN
     array(addr : addr+3) <= 0x00000000
  IF size = 11 THEN
     array(addr : addr+15) <= 0x00000000000000000000000000000000
END IF;
```

7.3.3 Coprocessor Execution Opcodes

The coprocessor execution opcodes are used to initiate operations or synchronize operations with the coprocessors. The execution type opcodes initiate accesses on the processor execution interface (PEI). A command to a coprocessor consists of six bits of coprocessor operation and 44 bits of coprocessor arguments. The definition of the operation and argument bits is coprocessor dependent.

A coprocessor can operate synchronously or asynchronously. Synchronous operation means the execution of the thread initiating the coprocessor command stalls until the coprocessor operation is complete. Asynchronous operation means the executing thread will not stall when a coprocessor execution command is issued, but rather can continue operating on the instruction stream. It is important to re-synchronize a coprocessor command that was issued asynchronously before using resources that the coprocessor needs for execution of the command. This can be done with the “wait” coprocessor execution opcodes.

The CLP runs the instruction stream of two threads in which only one thread can actually execute in a given cycle. The CLP thread that owns priority cannot be stalled by the execution of the non-priority thread. Priority is granted to the only active thread in a CLP or to the thread that is given priority by the other thread. The coprocessor execution opcodes indicated by the P bit in the following opcode map can give up the priority status of the thread.

Type	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
execute direct	1	1	1	1	C#				p	CPop					a	0	Immed16															
execute indirect	1	1	1	1	C#				p	CPop					a	1	R				Immed12											
execute direct conditional	1	1	1	0	C#				Cond				op		0	1	Immed16															
execute indirect conditional	1	1	1	0	C#				Cond				op		1	1	R				Immed12											
wait	1	1	1	0	0	0	0	0	p	0	0	0	0	0	0	0	mask16															
wait and branch	1	1	1	0	C#				p	0	0	0	1	0	ok	0	Target16															

7.3.3.1 Execute Direct Opcode

The execute direct opcode initiates a coprocessor command in which all of the operation arguments are passed immediately to the opcode. The C# field indicates which coprocessor will execute the command. The CPopfield is the coprocessor operation field. The Immed16 field contains the operation arguments that are passed with the command. The a field indicates whether the command should be executed asynchronously. The p field indicates if the thread should give up priority.

pseudocode:

```
exe.coprocessor number     <= C#
  exe.coprocessor operation  <= CPop
  exe.coprocessor arguments <=  "00000000000000000000000000000000" & Immed16

  coprocessor <= exe

  IF a=1 THEN
     PC <= PC+1
  ELSE
     PC <= stall
  END IF

  IF p=1 THEN
    PriorityOwner(other thread)<= TRUE
  ELSE
    PriorityOwner(other thread)<= PriorityOwner(other thread)
  END IF;
```

7.3.3.2 Execute Indirect Opcode

The execute indirect opcode initiates a coprocessor command in which the operation arguments are a combination of a GPR register and an immediate field. The field C# indicates which coprocessor the command is to be executed on. The field CPop is the coprocessor operation field. The R field is the GPR register to be passed as part of the operation arguments. The Immed12 field contains the immediate operation arguments that are passed. The a field indicates whether the command should be executed asynchronously. The p field indicates if the thread should give up priority.

pseudocode:

```
exe.coprocessor number     <= C#
  exe.coprocessor operation  <= CPop
  exe.coprocessor arguments <= Immed12 & GPR(R)

  coprocessor <= exe

  IF a=1 THEN
     PC <= PC+1
  ELSE
     PC <= stall
  END IF

  IF p=1 THEN
    PriorityOwner(other thread)<= TRUE
  ELSE
    PriorityOwner(other thread)<= PriorityOwner(other thread)
  END IF;
```

7.3.3.3 Execute Direct Conditional Opcode

The execute direct conditional opcode is similar to the execute direct opcode except that the execute direct conditional opcode command can be issued conditionally based on the Cond field. To make room in the opcode for the Cond field, the coprocessor opcode field (op) is shortened to two bits. Because the high order four bits of the coprocessor operation are assumed to be zeros, conditional operations are restricted to the lower four commands of a coprocessor. he command is assumed to be synchronous because the opcode does not have a bit to indicate whether it is asynchronous or synchronous. Priority cannot be released with this opcode.

pseudocode:

```
IF (Cond) THEN
     exe.coprocessor number      <= C#
     exe.coprocessor operation   <= “0000”&op
  exe.coprocessor arguments <=  “00000000000000000000000000000000” & Immed16

     coprocessor <= exe
  END IF
```

7.3.3.4 Execute Indirect Conditional Opcode

The execute indirect conditional opcode is similar to the execute indirect opcode except that the execute indirect command can be issued conditionally based on the Cond field. To make room in the opcode for the Cond field, the coprocessor opcode field (op) is shortened to two bits. Because the high order four bits of the coprocessor operation are assumed to be 0s, conditional operations are restricted to the lower four commands of a coprocessor. The command is assumed to be synchronous because the opcode does not have a bit to indicate whether it is asynchronous or synchronous. Priority cannot be released with this opcode.

pseudocode:

```
IF (Cond) THEN
     exe.coprocessor number      <= C#
     exe.coprocessor operation   <= "0000"&op
     exe.coprocessor arguments  <= Immed12 & GPR(R)

     coprocessor <= exe
  END IF
```

7.3.3.5 Wait Opcode

The wait opcode synchronizes one or more coprocessors. The mask16 field (see the register bit list table in *Section 7.3.3* on page 208) is a bit mask (one bit per coprocessor) in which the bit number corresponds to the coprocessor number. The thread stalls until all coprocessors indicated by the mask complete their operations. Priority can be released with this command.

pseudocode:

```
IF Reduction_OR(mask16(i)=coprocessor.busy(i)) THEN
   PC <= stall
ELSE
   PC <= PC + 1
END IF

IF p=1 THEN
  PriorityOwner(other thread)<= TRUE
ELSE
  PriorityOwner(other thread)<= PriorityOwner(other thread)
END IF;
```

7.3.3.6 Wait and Branch Opcode

The wait and branch opcode synchronizes with one coprocessor and branch on its one bit OK/KO flag. This opcode causes the thread to stall until the coprocessor represented by C# is no longer busy. The OK/KO flag is then compared with the field OK. If they are equal, the thread branches to the address in the target16 field. Priority can be released with this command.

pseudocode:

```
IF coprocessor.busy(C#)=1 THEN
   PC <= stall
ELSIF coprocessor.ok(C#)=ok THEN
   PC <= target16
ELSE
   PC <= PC+1
END IF

IF p=1 THEN
  PriorityOwner(other thread)<= TRUE
ELSE
  PriorityOwner(other thread)<= PriorityOwner(other thread)
END IF;
```

7.3.4 ALU Opcodes

ALU opcodes are used to manipulate GPR registers with arithmetic and logical functions. All of these opcodes execute in a single cycle. These opcodes are also used to manipulate the ALU status flags used in condition execution of opcodes. All ALU opcodes are executed conditionally based upon the Cond field.

7.3.4.1 Arithmetic Immediate Opcode

Type	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Arithmetic Immediate	1	0	0	0	i	ot3i			Cond				R				Imm12(11:8)				AluOp				Imm12(7:0)							
Logical Immediate	1	0	0	1	i	h	Lop		Cond				R				Immed16															
Compare Immediate	1	0	1	0	0	0	ot2i		Cond				R				Immed16															
Load Immediate	1	0	1	1	ot4i				Cond				R				Immed16															
Arithmetic/ Logical Register	1	1	0	0	i	ot3r			Cond				Rd				Rs				AluOp				0	0	0	0		h	n	m
Count Leading Zeros	1	0	1	0	1	hd	w	i	Cond				Rd				Rs				0	0	0	0	0	0	0	0	0	h	n	0

The arithmetic immediate opcode performs an arithmetic function on a GPR register in which the second operand is a 12-bit immediate value. The word GPR operand and destination GPR are specified in the R field and the immediate operand is represented by Imm4&Imm8. The actual portion of the GPR and extension of the immediate operand are shown in the ot3i table. The arithmetic function performed is given in the AluOp field. This AluOp functions of AND, OR, XOR, TST, and COMPARE are not used with this opcode and have a different opcode when the second operand is an immediate value. Arithmetic opcodes can be performed without changing the ALU status flags if the i field is a 1.

pseudocode:

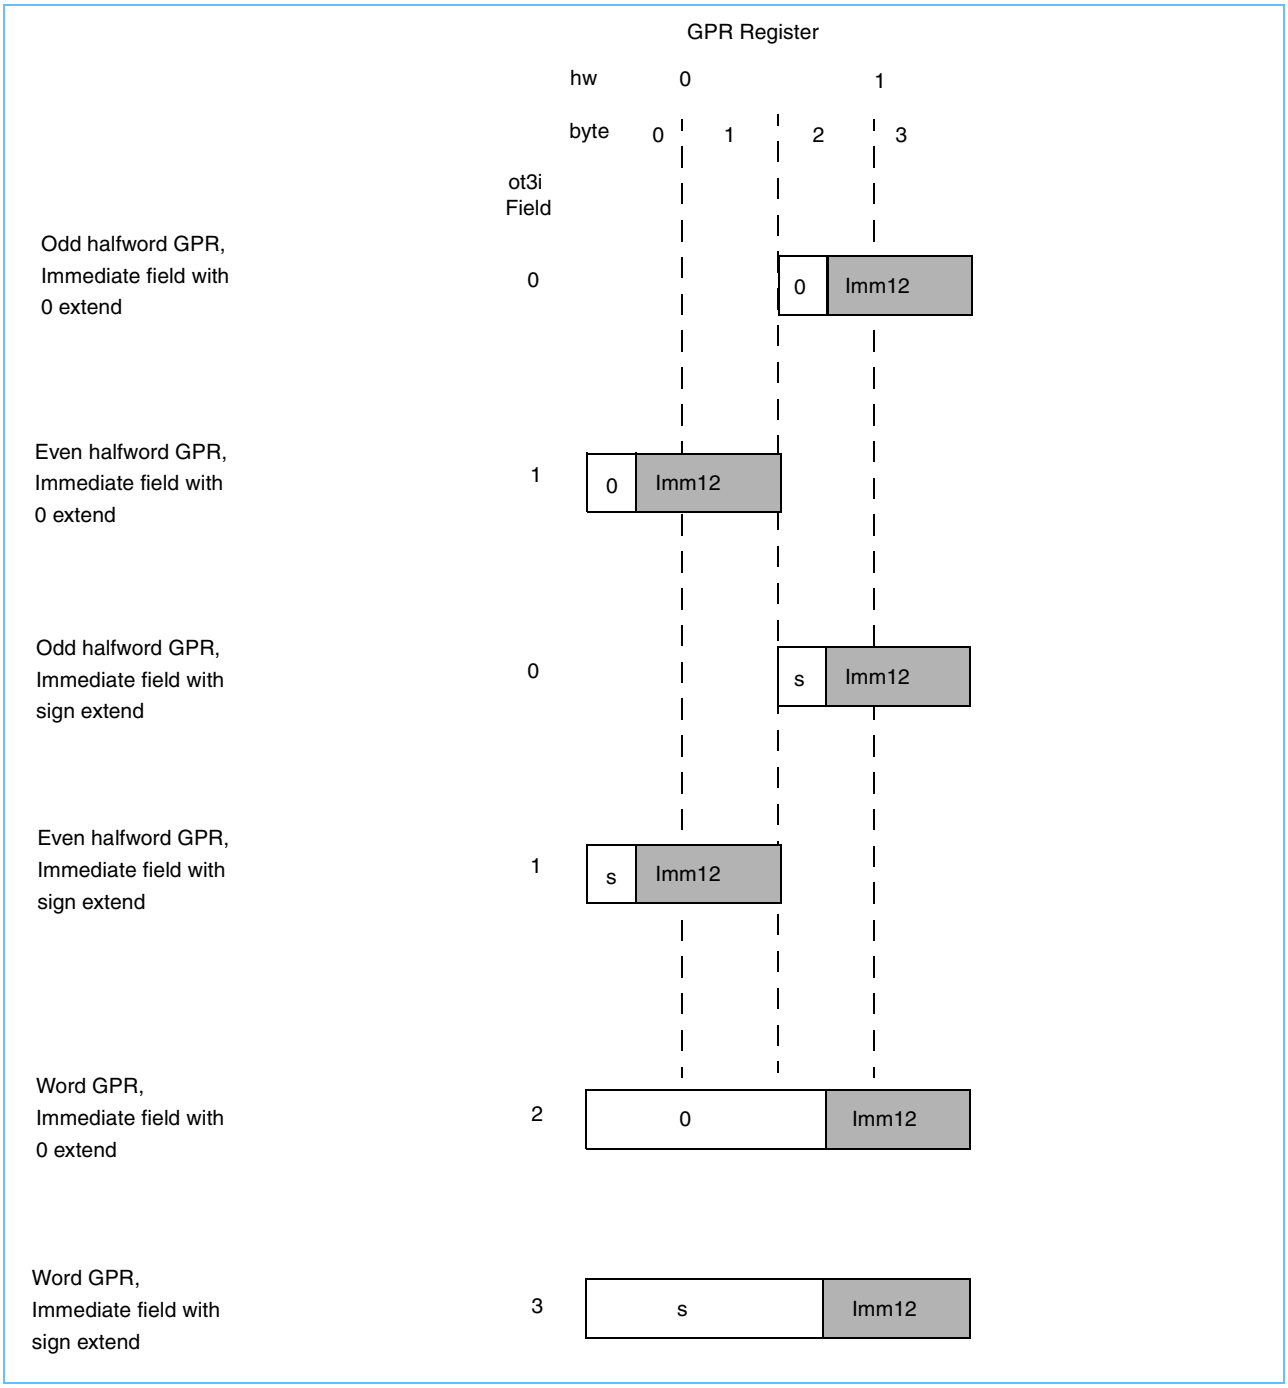
```
IF (Cond) THEN
     alu.opr1          <= GPR(R,ot3i)
     alu.opr2          <= ot3i(Immed4&Immed8)

     GPR(R,ot3i) <= Aluop.result(alu.opr1,alu.opr2)
     IF (i=0) THEN
        AluStatus <= Aluop.flags(alu.opr1, alu.opr2)
     END IF
END IF
```

Table 7-4. AluOp Field Definition

AluOp	Function	Pseudocode	Flags Modified			
			Z	C	N	V
0000	add	result = opr1 + opr2	x	x	x	x
0001	add w/carry	result = opr1 + opr2 + C	x	x	x	x
0010	subtract	result = opr1 - opr2	x	x	x	x
0011	subtract w/carry	result = opr1 - opr2 - C	x	x	x	x
0100	xor	result = orp1 XOR opr2	x		x	
0101	and	result = opr1 AND opr2	x		x	
0110	or	result = opr1 OR opr2	x		x	
0111	shift left logical	result = $opr1_{<-opr2}$, fill with 0s C = C when opr2 = 0 else C = 0 when opr2 > n else C = opr1(n - opr2); where n = size of opr1	x	x	x	
1000	shift right logical	result = fill with 0, $opr1_{->opr2}$ C = C when opr2 = 0 else C = 0 when opr2 > n else C = opr1(opr2 - 1); where n = size of opr1	x	x	x	
1001	shift right arithmetic	result = fill with S, $opr1_{->opr2}$ C = C when opr2 = 0 else C = opr1(n - 1) when opr2 > n else C = opr1(opr2 - 1); where n = size of opr1	x	x	x	
1010	rotate right	result = fill with opr1, $opr1_{->opr2}$ C = C when opr 2 = 0 else C= opr1(MODn(opr2 - 1)); where n = size of opr1	x	x	x	
1011	compare	opr1 - opr2	x	x	x	x
1100	test	opr1 AND opr2	x		x	
1101	not	result = NOT(opr1)	x		x	
1110	transfer	result = opr2				
1111	reserved	reserved				

Figure 7-9. ot3i Field Definition



7.3.4.2 Logical Immediate Opcode

The logical immediate opcode performs the logical functions AND, OR, XOR, and TEST on a GPR register in which the second operand is a 16-bit immediate value. the R field specifies the word GPR operand and destination GPR, and the h field specifies the even (h = 0) or odd (h = 1) halfword of this GPR. The immediate operand is represented by Imm16. The arithmetic function performed is given in the Lop field. Logical opcodes can be performed without changing the ALU status flags if the i field is a 1.

pseudocode:

```
IF (Cond) THEN
     alu.opr1         <= GPR(R:h)
     alu.opr2         <= Immed16

     GPR(R:h) <= Lop.result(alu.opr1,alu.opr2)
     IF (i=0) THEN
        AluStatus <= Lop.flags(alu.opr1, alu.opr2)
     END IF
END IF
```

Table 7-5. Lop Field Definition

LOp	Function	Pseudocode	Flags Modified			
			Z	C	N	V
00	xor	result = orp1 XOR opr2	x		x	
01	and	result = opr1 AND opr2	x		x	
10	or	result = opr1 OR opr2	x		x	
11	test	opr1 AND opr2	x		x	

7.3.4.3 Compare Immediate Opcode

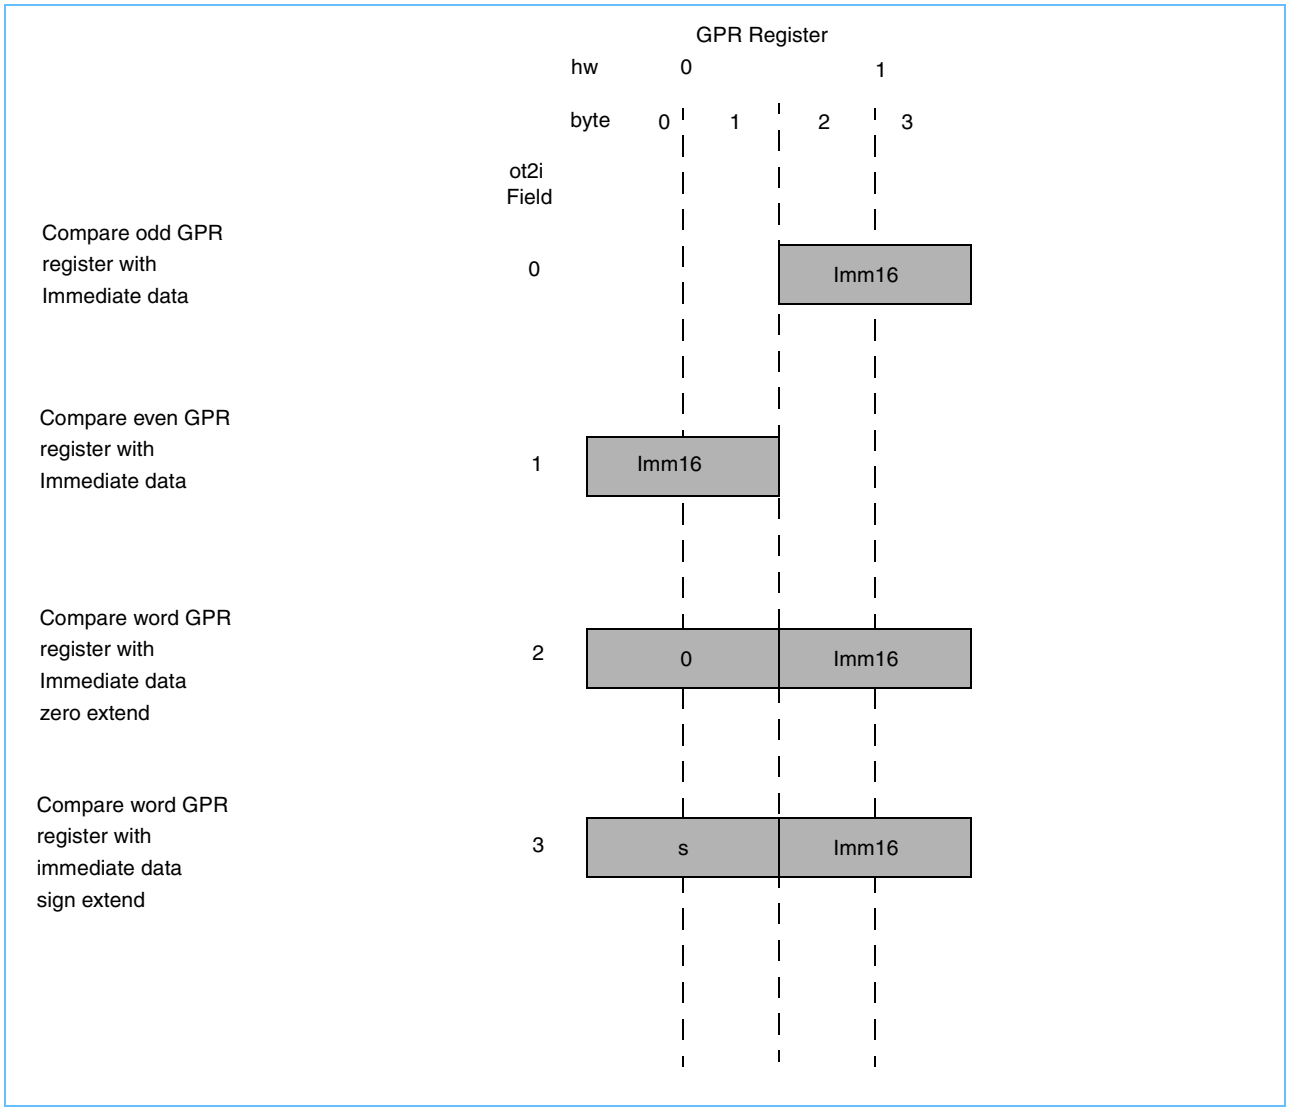
The compare immediate opcode performs the compare functions on a GPR register in which the second operand is a 16-bit immediate value. The source GPR operand and destination GPR are specified in the R field, and the immediate operand is represented by Imm16. The actual portion of the GPR and extension of the immediate operand are shown in *Figure 7-10*. The compare immediate opcode always changes the ALU status flags.

pseudocode:

```
IF (Cond) THEN
     alu.opr1         <= GPR(R,ot2i)
     alu.opr2         <= ot2i(Immed16)

     AluStatus <= compare(alu.opr1, alu.opr2)
   END IF
```

Figure 7-10. ot2i Field Definition: Compare Halfword/Word Immediate



7.3.4.4 Load Immediate Opcode

The operation arguments of the load immediate opcode are a combination of a GPR register and a 16-bit immediate field. The source GPR operand and destination GPR are specified by the R field and the immediate operand is represented by Imm16. The actual portion of the GPR and extension of the immediate operand are shown in *Figure 7-11* and *Figure 7-12*. Load immediate opcode never changes the ALU status flags if executed.

pseudocode:

```
IF (Cond) THEN
     GPR(R,ot4i) <= ot4i(Immed16)
   END IF
```

Figure 7-11. ot4i Field Definition Load Immediate Halfword/Word

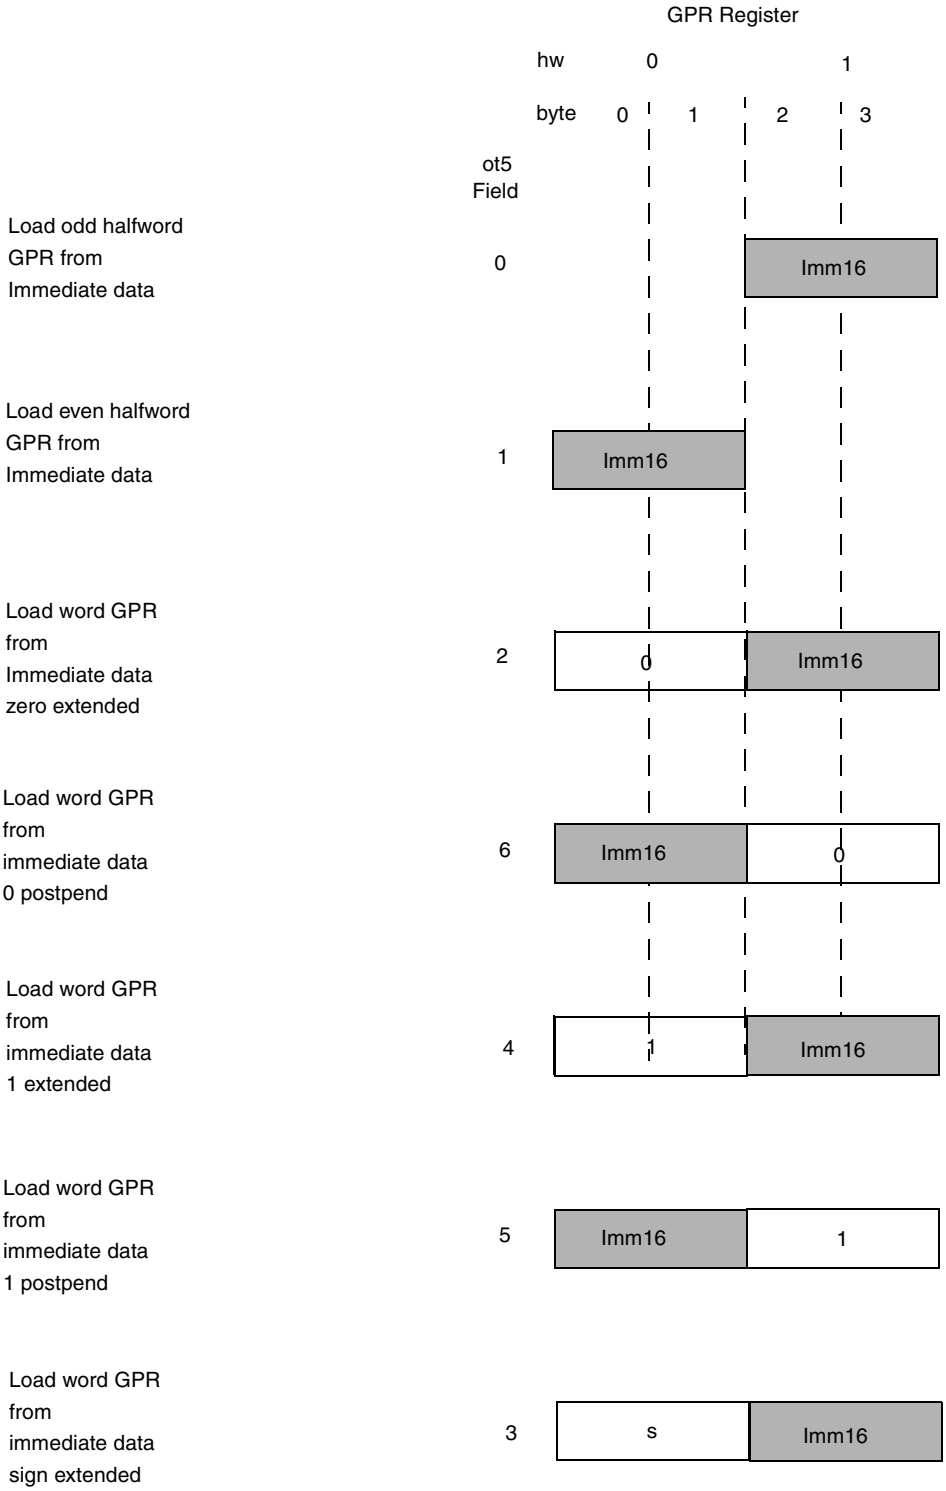


Figure 7-12. ot4i Field Definition: Load Immediate Byte

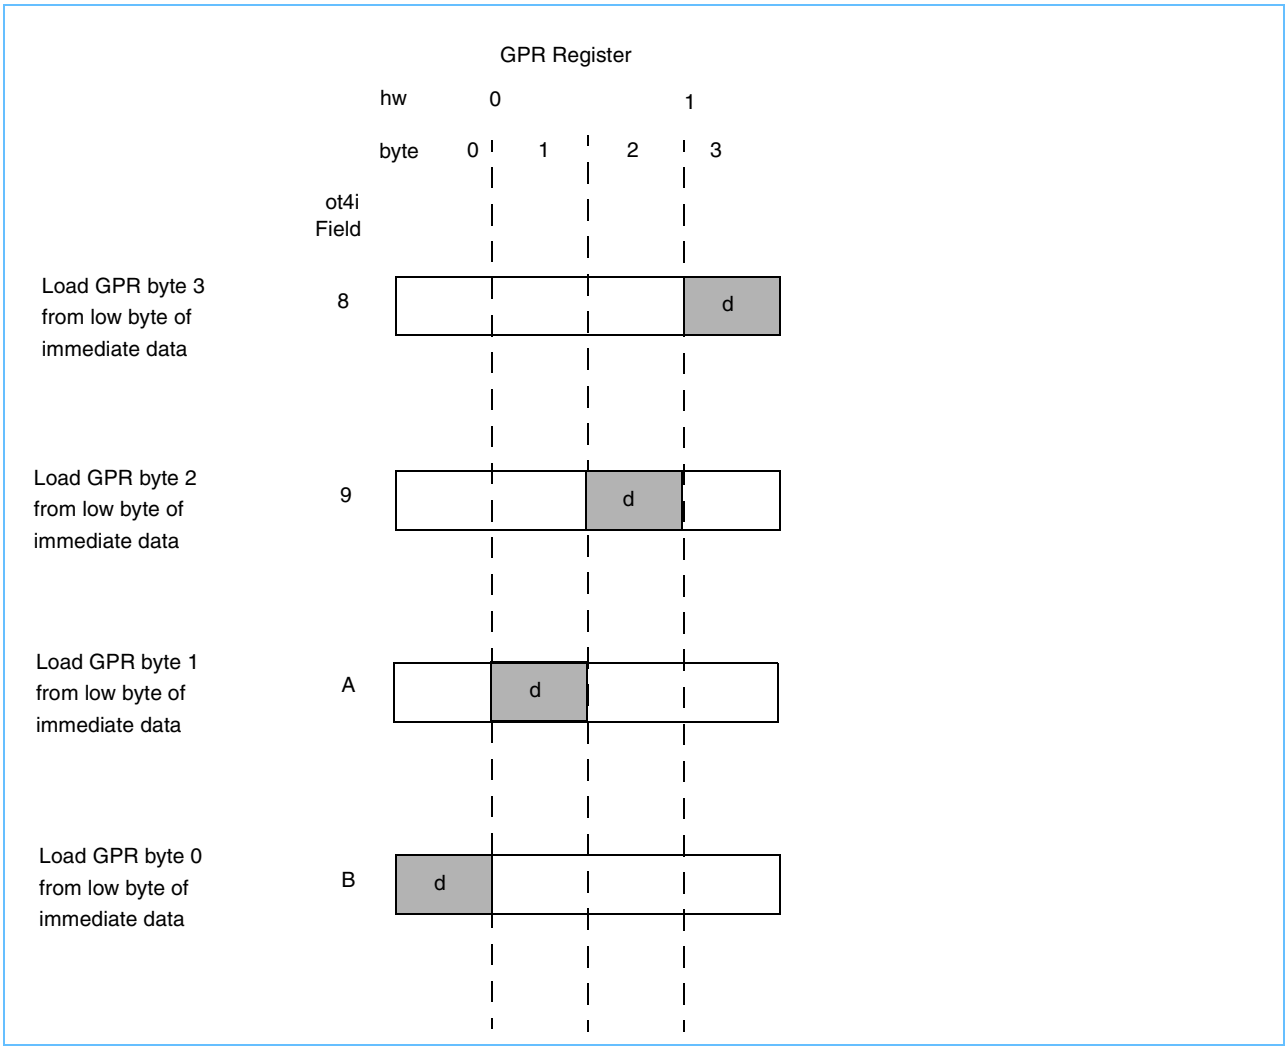


7.3.4.5 Arithmetic Register Opcode

The arithmetic register opcode performs an arithmetic function on a GPR register in which the second operand is also a GPR register. The first GPR operand and the destination GPR are specified by the word address R1 and the specific portion to be used is encoded in ot3r. The second operand source is represented by word address R2 with the h field determining the even or odd halfword if the ot3r field indicates a halfword is needed. If the AluOp is a shift or rotate command, the second operand source is used as the amount of the shift or rotate. Otherwise, ot3r indicates the relationship between the two operands. If the AluOp is a logical operation (AND, OR, XOR, TEST), the second operand source can then further be modified by the m and n fields. The m field is the mask field and, if active, creates a 1-bit mask in which the “1” bit is represented by the second operand source. The n field is the invert field and, if active, will invert the second operand source. If both the m and n fields are “1”, the mask is created before the inversion. *Table 7-6* show how to use these fields to create other operations from the basic logic commands. The arithmetic function performed is given in the AluOp field. Arithmetic opcodes can be performed without changing the ALU status flags if the “i” field is a 1.

pseudocode:

```
IF (Cond) THEN
     alu.opr1         <= GPR(R1,ot3r)
     alu.opr2         <= GPR(R2,h)

     IF ‘m’=’1’ THEN
       alu.opr2 <= bitmask(alu.opr2)
    END IF

    IF ‘n’=’1’ THEN
      alu.opr2 <= NOT(alu.opr2)
   END IF

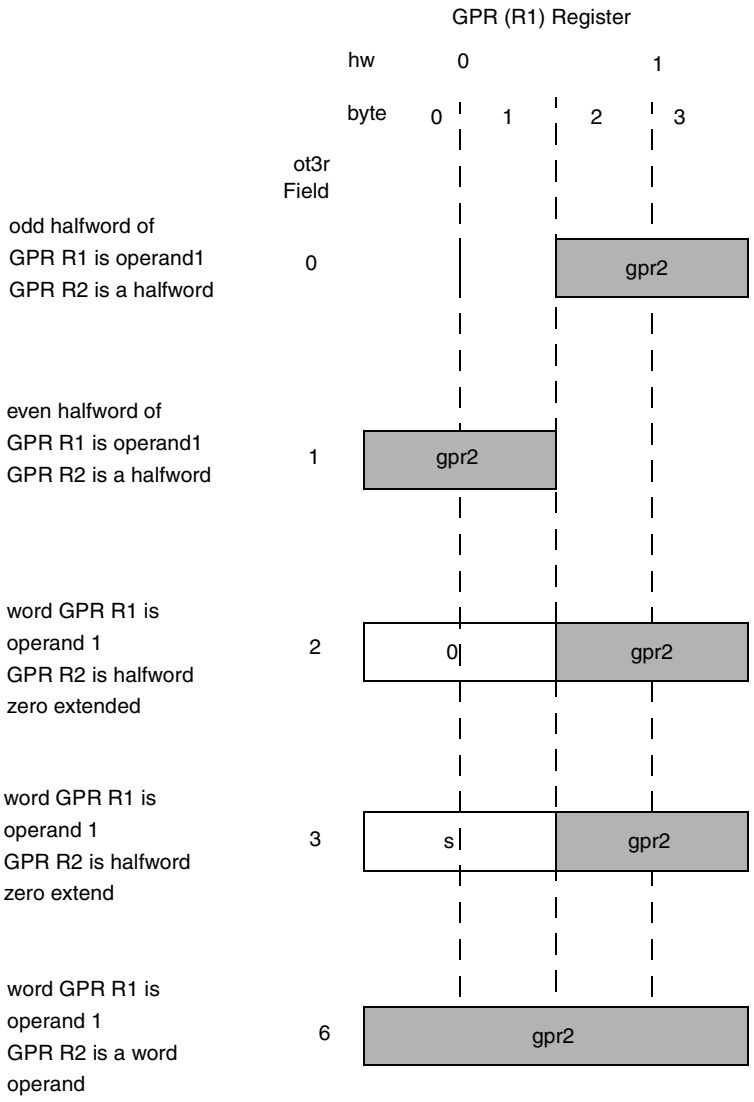
     GPR(R2,ot3i) <= Aluop.result(alu.opr1,alu.opr2)

     IF (i=0) THEN
        AluStatus <= Aluop.flags(alu.opr1, alu.opr2)
     END IF
END IF
```

Table 7-6. Arithmetic Opcode Functions

Function	AluOp	m	n
Bit clear	AND	1	1
Bit set	OR	1	0
Bit flip	XOR	1	0

Figure 7-13. ot3r Field Definition



7.3.4.6 Count Leading Zeros Opcode

The count leading zeros opcode returns the number of zeros from left to right until the first 1-bit is encountered. This operation can be performed on a halfword or word GPR register. There is a second variation of this command in which the return value of this command is the bit position of the first “1” from left to right in the GPR. The GPR to be analyzed is determined by the R fields. If the GPR is a halfword instruction, the h field indicates whether the even or odd half is used. The destination register is always a halfword register and is represented by the Rd field and halfword indicator ‘hd’. The w field indicates whether the operation is a word or halfword. The n field determines if the command counts the number of leading zeros (n = 0) or if the command returns the bits position of the first one (n = 1). The only flag for this command is the overflow flag, which is set if the GPR being tested contains all zeros. The setting of this flag can be inhibited if the i field is a one.

pseudocode:

```
IF (Cond) THEN
     alu.opr1         <= GPR(Rs,h)

    alu.result <= count_zero_left_to_right(alu.opr1)

    IF ‘n’=’1’ THEN
      GPR(Rd,hd) <= NOT(alu.result)
    ELSE
      GPR(Rd,hd) <= alu.result
   END IF

     IF (i=0) THEN
        AluStatus <= Aluop.flags(alu.opr1, alu.opr2)
     END IF
END IF
```

7.4 DPPU Coprocessors

Each DPPU coprocessor is a specialized hardware assist engine that runs in parallel with the two CLPs and performs functions that would otherwise require a large amount of serialized picocode. DPPU functions include modifying IP headers, maintaining flow information used in flow control algorithms, accessing internal registers via the CAB, maintaining counts for flow control and for standard and proprietary Management Information Blocks (MIB), and enqueueing frames to be forwarded.

The DPPU coprocessors are:

Tree Search Engine	See *Section 8. Tree Search Engine* on page 289.
Data Store	See *Section 7.4.2* beginning on page 224.
Control Access Bus (CAB) Interface	See *Section 7.4.3* beginning on page 239.
Enqueue	See *Section 7.4.4* beginning on page 242.
Checksum	See *Section 7.4.5* beginning on page 256.
String Copy	See *Section 7.4.6* beginning on page 261.
Policy	See *Section 7.4.7* beginning on page 262.
Counter	See *Section 7.4.8* beginning on page 263.
Semaphore	See *Section 7.4.9* beginning on page 266.

A thread's address space is a distributed model in which registers and arrays reside within the coprocessors (each coprocessor maintains resources for four threads and, for address mapping purposes, the CLP is considered to be a coprocessor). Each coprocessor can have a maximum of 252 scalar registers and four arrays.

The address of a scalar register or array within the DPPU becomes a combination of the coprocessor number and the address of the entity within the coprocessor. Likewise, the coprocessor instruction is a combination of the coprocessor number and the coprocessor opcode.

The EPC coprocessors are numbered as shown in *Table 7-7*. The number is used in accesses on both the coprocessor execute and data interfaces. The TSE is mapped to two coprocessor locations so that a thread can execute two searches simultaneously.

Table 7-7. Coprocessor Instruction Format

Coprocessor Number	Coprocessor
0	Core Language Processor (CLP)
1	Data Store Interface
2	Tree Search Engine 0
3	Tree Search Engine 1
4	CAB Interface
5	Enqueue
6	Checksum
7	String Copy
8	Policy
9	Counter
10	Reserved
11	Semaphore

7.4.1 Tree Search Engine Coprocessor

The Tree Search Engine (TSE) coprocessor has commands for tree management, direct access to the Control Store (CS), and search algorithms such as full match (FM), longest prefix match (LPM), and software-managed tree (SMT).

For complete information, see *Section 8. Tree Search Engine* on page 289.

7.4.2 Data Store Coprocessor

The Data Store coprocessor provides an interface between the EPC and the Ingress Data Store, which contains frames that have been received from the media, and the Egress Data Store, which contains reassembled frames received from the switch interface. The Data Store coprocessor also receives configuration information during the dispatch of a timer event or interrupt.

Each thread supported by the Data Store coprocessor has one set of scalar registers and arrays defined for it. The scalar registers control the accesses between the shared memory pool and the ingress and egress data stores. The Data Store coprocessor maintains them. The arrays are defined in the shared memory pool (see *7.2.4 Shared Memory Pool* on page 193):

- The DataPool, which can hold eight quadwords
- Two scratch memory arrays, which hold eight and four quadwords respectively
- The configuration quadword array, which holds port configuration data dispatched to the thread.

The shared memory pool arrays function as a work area for the Data Store coprocessor: instead of reading or writing small increments (anything less than a quadword, or 16 bytes) directly to a data store, a larger amount (one to four quadwords per operation) of frame data is read from the data store into these shared memory pool arrays or from the these arrays into the data store.

The Data Store coprocessor has nine commands available to it. These commands are detailed in *Section 7.4.2.2 Data Store Coprocessor Commands* on page 230.

7.4.2.1 Data Store Coprocessor Address Map

Table 7-8. Data Store Coprocessor Address Map (A thread's scalar registers and arrays that are mapped within the Data Store coprocessor)

Name	Register (Array)[1] Number	Size (bits)	Access	Description
DSA	x'00'	19	R/W	Address of Ingress or Egress Data Store. Used in all commands except "read more" and "dirty". (Ingress uses the least significant 11 bits and Egress uses all 19 bits for the address.)
LMA	x'01'	6	R/W	Quadword address of Shared Memory Pool. Used in all commands except "read more". (See *7.2.4 Shared Memory Pool* on page 193.)
CCTA	x'02'	19	R/W	Current address of the ingress data buffer or the egress twin that was dispatched to the thread into the datapool. Used in "read more" and "dirty" commands. The value is unitized at dispatch and updated on "read more" commands that pass though cell or twin boundaries.
NQWA	x'03'	3	R/W	Indicates the QW address used for both the Datapool and the QW in the datastore buffer/twin. See *EDIRTY (Update Egress Dirty Quadwords) Command* on page 237, *IDIRTY (Update Ingress Dirty Quadwords) Command* on page 238, *RDMOREE (Read More Quadword From Egress) Command* on page 235, and *RDMOREI (Read More Quadword From Ingress) Command* on page 236 for details.
iProtocolType	x'04'	16	R	Layer 3 Protocol identifier set by the hardware classifier (see *7.7 Hardware Classifier* on page 275).
DirtyQW	x'05'	8	R/W	Quadwords in the DataPool that have been written and therefore may not be equivalent to the corresponding Data Store data. Used by the dirty update commands to write back any modified data into the corresponding Data Store.
BCI2Byte	x'06'	14/20	R/W	A special-purpose register. The picocode running in the CLP writes a 20-bit BCI value, but when the register is read, it returns the 14-bit byte count represented by the BCI.
Disp_DSU	x'07'	2	R/W	Initialized during dispatch to contain the same value as the DSU field in the Egress FCBPage. This register is used by Egress write commands to determine which Egress Data Store the Data Store coprocessor should access when writing data. This register has no meaning for Ingress frames.
Disp_DSUSel	x'08'	1	R/W	Initialized during dispatch to contain the same value as the DSU_Sel field in the Egress FCBPage. This register is used by Egress read commands to determine which Egress Data Store the Data Store coprocessor should access when reading data. This register has no meaning for Ingress frames.
Disp_Ingress	x'09'	1	R	Dispatched frame's type 0 Egress frame 1 Ingress frame
ConfigQW	x'FC' (0)	128	R/W	Port Configuration Table Entry for this frame
ScratchMem0	x'FD' (1)	512	R/W	User Defined Array (use to store temporary information, build new frames, and so on)
ScratchMem1	x'FE' (2)	1024	R/W	User Defined Array (use to store temporary information, build new frames, and so on)
DataPool	x'FF' (3)	1024	R/W	Contains frame data from the Dispatch Unit

1. A number in parentheses is the array number for this coprocessor. Each array has a register number and an array number.

The DataPool and Data Store Access

Upon frame dispatch, the Dispatch Unit automatically copies the first N quadwords of a frame from the Data Store into the first N quadword positions of the DataPool. The value of N is programmable in the Port Configuration Memory. Typically, values of N are as follows:

N = 4	Ingress frame dispatch
N = 2	Egress unicast frame dispatch
N = 4	Egress multicast frame dispatch
N = 0	Interrupts and timers

The read more commands (RDMOREI and RDMOREE) assist the picocode's reading of additional bytes of a frame by automatically reading the frame data into the DataPool at the next quadword address and wrapping automatically to quadword 0 when the boundary of the DataPool is reached. The picocode can also read or write the Ingress and Egress Data Stores at an absolute address, independent of reading sequential data after a dispatch.

The DataPool for Ingress Frames

For an Ingress Dispatch, the N quadwords are stored in the DataPool at quadword-address 0, 1, … N - 1. Each quadword contains raw frame-bytes, (there are no cell header or frame headers for ingress frames in the DataPool). After an Ingress Dispatch, the DataPool contains the first N*16 bytes of the frame, where the first byte of the frame has byte address 0. The Ingress DataPool Byte Address Definitions are listed in *Table 7-9*.

Table 7-9. Ingress DataPool Byte Address Definitions

Quadword	Byte Address															
0	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
1	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
2	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
3	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
4	64	65	66	67	68	69	70	71	72	73	74	75	76	77	78	79
5	80	81	82	83	84	85	86	87	88	89	90	91	92	93	94	95
6	96	97	98	99	100	101	102	103	104	105	106	107	108	109	110	111
7	112	113	114	115	116	117	118	119	120	121	122	123	124	125	126	127

When reading more than N quadwords of a frame (using the RDMOREI command), the hardware automatically walks the Data Store's buffer control block (BCB) chain as required. Quadwords read from the Data Store are written to the DataPool at consecutive quadword-locations, starting at quadword address N (where N is the number of quadwords written to the DataPool by the Dispatch Unit during frame dispatch). The quadword-address wraps from 7 - 0. Therefore, the picocode must save quadword 0 in case it is required later (for example, the quadword can be copied to a scratch array).

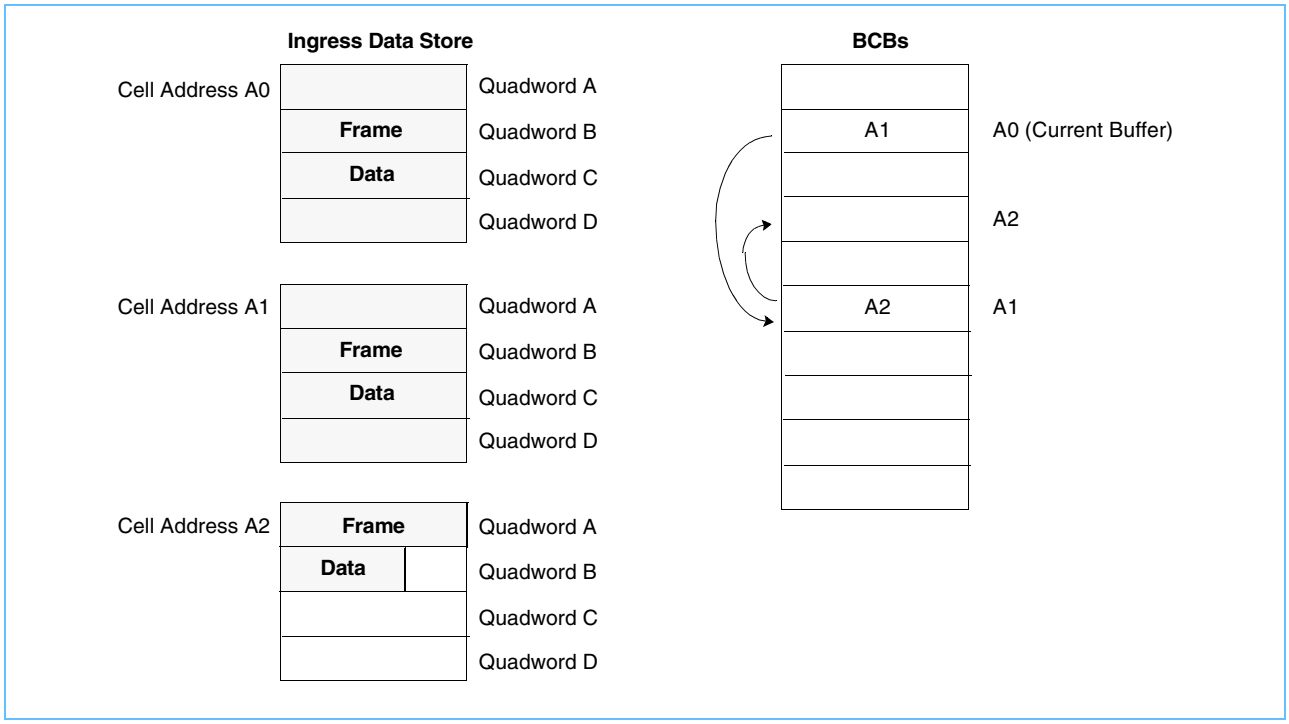
The Ingress Data Store can also be written and read with an absolute address. The address is a BCB address.

Reading from an absolute address can be used for debugging and to inspect the contents of the Ingress DS.

For absolute Ingress Data Store access (reads and writes), the picocode must provide the address in the Ingress Data Store, the quadword address in the DataPool, and the number of quadwords to be transferred.

Figure 7-14 shows an example of a frame stored in the Ingress Data Store:

Figure 7-14. A Frame in the Ingress Data Store



The DataPool for Egress Frames

For an Egress Dispatch, the N quadwords are stored in the DataPool at a starting quadword-address that is determined by where the frame header starts in the twin, which in turn depends on how the frame is packed in the Switch cell and stored in the Egress Data Store (see *Figure 7-15*). General-purpose register (GPR) R0 is initialized during dispatch as shown in *Table 7-10: Egress Frames DataPool Quadword Addresses* on page 228. GPR R0 can be used as an index into the DataPool so that the variability of the location of the start of the frame in the datapool is transparent to the picocode.

Figure 7-15. Frame in the Egress Data Store (Illustrating the effects of different starting locations)

Table 7-10. Egress Frames DataPool Quadword Addresses

Frame Start In Twin Buffer	Frame Quadword Address in the DataPool	GPR R0
Quadword A	0	0
Quadword B	1	10
Quadword C	2	26
Quadword D	3	42

The relationship between quadwords A, B, C, and D in the twin buffer and the location of the quadword in the DataPool is always maintained. That is, Quadword A is always stored at quadword address 0 or 4, Quadword B is always stored at quadword address 1 or 5, Quadword C is always stored at quadword address 2 or 6, and Quadword D is always stored at quadword address 3 or 7.

In contrast with the ingress side, the Egress DataPool contains cell headers. When the exact content of the twin-buffer is copied into the DataPool, it may include the 6-byte NP4GS3 cell header if the quadword being copied comes from Quadword A in the twin buffer.

The DataPool can be accessed in two modes:

- Normal DataPool access:
  Accesses all bytes in the DataPool, including the 6-byte cell header. For example, it can be used for guided frames where information in the cell header may be important, or for debugging and diagnostics.
- Cell Header Skip DataPool access:
  Automatically skips the cell header from the DataPool. The hardware assumes a cell header to be present at quadword-address 0 and 4. For example, accessing DataPool[2] accesses the byte with physical address 8, DataPool[115] accesses the byte with physical address 127, and DataPool[118] also accesses the byte with physical address 8. The maximum index that can be used for this access mode is 231. This mode is shown in *Table 7-11*.

Table 7-11. DataPool Byte Addressing with Cell Header Skip

Quadword	Byte Address															
0	—	—	—	—	—	—	0 116	1 117	2 118	3 119	4 120	5 121	6 122	7 123	8 124	9 125
1	10 126	11 127	12 128	13 129	14 130	15 131	16 132	17 133	18 134	19 135	20 136	21 137	22 138	23 139	24 140	25 141
2	26 142	27 143	28 144	29 145	30 146	31 147	32 148	33 149	34 150	35 151	36 152	37 153	38 154	39 155	40 156	41 157
3	42 158	43 159	44 160	45 161	46 162	47 163	48 164	49 165	50 166	51 167	52 168	53 169	54 170	55 171	56 172	57 173
4	—	—	—	—	—	—	58 174	59 175	60 176	61 177	62 178	63 179	64 180	65 181	66 182	67 183
5	68 184	69 185	70 186	71 187	72 188	73 189	74 190	75 191	76 192	77 193	78 194	79 195	80 196	81 197	82 198	83 199
6	84 200	85 201	86 202	87 203	88 204	89 205	90 206	91 207	92 208	93 209	94 210	95 211	96 212	97 213	98 214	99 215
7	100 216	101 217	102 218	103 219	104 220	105 221	106 222	107 223	108 224	109 225	110 226	111 227	112 228	113 229	114 230	115 231

Fewer frame-bytes may be available in the DataPool for the Egress due to the presence of cell headers. *Table 7-12* shows the number of frame-bytes in the DataPool after a frame dispatch.

Table 7-12. Number of Frame-bytes in the DataPool

Number Of Quadwords Read	Start Quadword A	Start Quadword B	Start Quadword C	Start Quadword D	Guaranteed
1	10	16	16	16	10
2	26	32	32	26	26
3	42	48	42	42	42
4	58	58	58	58	58
5	68	74	74	74	68
6	84	90	90	84	84
7	100	106	100	100	100
8	116	116	116	116	116

For example, when 24 bytes of frame data are always needed, the Port Configuration Memory must be programmed with the N (number of quadwords to dispatch) equal to two. When 32 bytes are always needed, the number of quadwords to dispatch must be set to three.

After a dispatch, picocode can use the RDMOREE command when more frame data is required. One, two, three, or four quadwords can be requested. Consult the “Guaranteed” column in *Table 7-12* to translate the necessary number of bytes into the greater number of quadwords that must be read. For example, if the picocode must dig into the frame up to byte 64, five quadwords are required. In this example, the number of quadwords specified with the RDMOREE command equals 5 - N, where N is the number of quadwords initially written in the DataPool by the dispatch unit.

As a general rule, each set of four quadwords provides exactly 58 bytes.

7.4.2.2 Data Store Coprocessor Commands

The Data Store coprocessor provides the following commands:

Command	Opcode	Description
WREDS	0	Write Egress Data Store. Enables the CLP to read data from one of the arrays in the Shared Memory Pool (DataPool and Scratch Memory Array) and write it to the Egress Data Store (in multiples of quadwords only). For more information, see *WREDS (Write Egress Data Store) Command* on page 232.
RDEDS	1	Read Egress Data Store. Enables the CLP to read data from the Egress Data Store and write it into one of the arrays in the Shared Memory Pool (in multiples of quadwords only). For more information, see *RDEDS (Read Egress Data Store) Command* on page 232.
WRIDS	2	Write Ingress Data Store. Enables the CLP to write data to the Ingress data store (in multiples of quadwords only). For more information, see *WRIDS (Write Ingress Data Store) Command* on page 234.
RDIDS	3	Read Ingress Data Store. Enables the CLP to read data from the Ingress Data Store (in multiples of quadwords only). For more information, see *RDIDS (Read Ingress Data Store) Command* on page 234.

Command	Opcode	Description
RDMOREE	5	Read More Frame Data from the Egress Data Store. A hardware assisted read from the Egress Data Store. RDMOREE continues reading the frame from where the dispatch or last “read more” command left off and places the data into the DataPool. As data is moved into the DataPool, the hardware tracks the current location in the frame that is being read and captures the link pointer from the twin buffers in order to determine the address of the next twin buffer. This address is used by the hardware for subsequent RDMOREE requests until the twin is exhausted and the next twin is read. Since the DataPool is essentially a map of a twin's content, the frame data might wrap within the DataPool; the picocode keeps track of the data’s location within the DataPool. For more information, see *EDIRTY (Update Egress Dirty Quadwords) Command* on page 237
RDMOREI	7	Read More Frame Data from the Ingress Data Store. A hardware assisted read from the Ingress Data Store. RDMOREI continues reading the frame from where the dispatch or last “read more” command left off and places the data into the DataPool. As data is moved into the DataPool, the hardware tracks the current location in the frame that is being read and captures the link maintained in the buffer control block area in order to determine the address of the frame’s next data buffer. This address is used by the hardware for subsequent RDMOREI requests until the data buffer is exhausted and the next buffer is read. The picocode keeps track of the frame data’s location within the DataPool. For more information, see on page 236
LEASETWIN	8	Lease Twin Buffer. Returns the address of a free twin buffer. Use this command when creating new data in the Egress Data Store. For more information, see*7.4.3 Control Access Bus (CAB) Coprocessor on page 239*
EDIRTY	10	Update Dirty Quadword Egress Data Store. The coprocessor keeps track of the quadwords within the current twin that have been modified in the DataPool array. EDIRTY enables the CLP to write only the “dirty” data back to the Egress data store (in multiples of quadwords only). This command is only valid within the DataPool array and for the buffer represented by the scalar register Current Cell/Twin Address. For more information, see *EDIRTY (Update Egress Dirty Quadwords) Command* on page 237
IDIRTY	12	Update Dirty Quadword Ingress Data Store. The coprocessor keeps track of the quadwords within the current buffer that have been modified in the DataPool array. IDIRTY enables the CLP to write only the “dirty” data back to the Ingress Data Store (in multiples of quadword units only). This command is only valid within the DataPool array and for the buffer represented by the scalar register Current Cell/Twin Address. For more information, see *IDIRTY (Update Ingress Dirty Quadwords) Command* on page 238

Note: The Egress Data Store has a longer access time than the Ingress Data Store. For better performance, as much frame parsing should be done on the Ingress side as possible.

WREDS (Write Egress Data Store) Command

WREDS writes to an absolute address in the Egress Data Store. It can be specified if the quadwords are written to DS0, DS1, both DS0 and DS1, or if the decision is made automatically by information in the Dispatch DSU register.

Table 7-13. WREDS Input

		Operand Source		
Name	Size	Direct	Indirect	Description
NrOfQuadWord	2	Imm16(1..0)	GPR(1..0)	Defines the number of quadwords to be written: 01 1 quadword 10 2 quadwords 11 3 quadwords 00 4 quadwords
DSControl	2	Imm16(3..2)	Imm12(3..2)	Defines if the quadwords are written to DS0, DS1 or both: 00 Writes to the default DSU 01 Writes to DS0 10 Writes to DS1 11 Writes to DS0 and DS1
Disp_DSU	2	R		The default DSU, initialized at Dispatch
DSA	19	R		Data Store Address. The target twin address in the Egress Data Stores. The starting QW destination within the twin is determined by the 3 low-order bits of the LMA. 000 - 011 QW 0-3 of the first buffer of the twin. 100 - 111 QW 0-3 of the second buffer of the twin.
LMA	6	R		Local Memory Address. The quadword source address in the Shared Memory Pool (see *7.2.4 Shared Memory Pool* on page 193).

The Data Store Address can be any address in the Egress Data Store, but the picocode must ensure that no twin overflow occurs during writing. For example, it is not a good idea to make the LMA point to the last quadword in a 64-byte buffer and set NrOfQuadword to four.

Table 7-14. WREDS Output

		Operand Source		
Name	Size	Direct	Indirect	Description
LMA	6	R		Local Memory Address. The LMA will be the input value of the LMA incremented by the number of quadword transfers completed by the command.

RDEDS (Read Egress Data Store) Command

RDEDS reads from an absolute address in the Egress Data Store. It can be specified if the quadwords are read from DS0 or DS1, or if this decision is made automatically by information in the Dispatch DSU register.

Table 7-15. RDEDS Input

		Operand Source		
Name	Size	Direct	Indirect	Description
NrOfQuadWord	2	Imm16(1..0)	GPR(1..0)	Defines the number of quadwords to be read: 01 1 quadword 10 2 quadwords 11 3 quadwords 00 4 quadwords
DSControl	2	Imm16(3..2)	Imm12(3..2)	Defines if the quadwords are read from DS0 or DS1: 00 Reads from the default DS 01 Reads from DS0 10 Reads from DS1 11 Reserved
Disp_DSUSel	1	R		Indicates the default DS chosen at Dispatch. 0 DS0 1 DS1
DSA	19	R		Data Store Address. The source address in the Egress Data Store.
LMA	6	R		Local Memory Address. The quadword target address in the shared memory pool (see *7.2.4 Shared Memory Pool* on page 193).

When DSControl is set to 00, the quadwords are read from the default DS, which is determined based on the Dispatch DSUSel field.

Table 7-16. RDEDS Output

		Operand Source		
Name	Size	Direct	Indirect	Description
OK/KO (NP4GS3B (R2.0))	1	Flag		KO - An error occurred when reading the fourth quadword of a twin buffer indicating the link pointer contained in the data had a parity error. OK - Indicates that the link pointer had valid parity or that the link pointer wasn't read on this access.
LMA	6	R		Local Memory Address. The LMA will be the input value of the LMA incremented by the number of quadword transfers completed by the command.

WRIDS (Write Ingress Data Store) Command

WRIDS writes to an absolute address in the Ingress Data Store.

Table 7-17. WRIDS Input

		Operand Source		
Name	Size	Direct	Indirect	Description
NrOfQuadWord	2	Imm16(1..0)	GPR(1..0)	Defines the number of quadwords to be written: 01 1 quadword 10 2 quadwords 11 3 quadwords 00 4 quadwords
DSA	19	R		Data Store Address. The target address in the Ingress Data Store. The 11 LSBs of the DSA contain the address. The remaining eight MSBs are not used.
LMA	6	R		Local Memory Address. The quadword source address in the Shared Memory Pool (see *7.2.4 Shared Memory Pool* on page 193).

The Data Store Address (DSA) can be any address in the Ingress Data Store but the picocode must ensure that no buffer overflow occurs during writing. For example, it is not a good idea to make the DSA point to the last quadword in a 64-byte buffer and set NrOfQuadword to four.

Table 7-18. WRIDS Output

		Operand Source		
Name	Size	Direct	Indirect	Description
LMA	6	R		Local Memory Address. The LMA will be the input value of the LMA incremented by the number of quadword transfers completed by the command.

RDIDS (Read Ingress Data Store) Command

RDIDS reads from an absolute address in the Ingress Data Store.

Table 7-19. RDIDS Input

		Operand Source		
Name	Size	Direct	Indirect	Description
NrOfQuadWord	2	Imm16(1..0)	GPR(1..0)	Defines the number of quadwords to be read: 01 1 quadword 10 2 quadwords 11 3 quadwords 00 4 quadwords
DSA	19	R		Data Store Address. The source address in the Ingress Data Store
LMA	6	R		Local Memory Address. The quadword target address in the Shared Memory Pool (see *7.2.4 Shared Memory Pool* on page 193).

The Data Store Address (DSA) can be any address in the Ingress Data Store. The picocode must ensure that no buffer overflow occurs during reading. For example, it is not a good idea to make the DSA point to the last quadword in a 64-byte buffer and set NrOfQuadword to four.

Table 7-20. RDIDS Output

		Operand Source		
Name	Size	Direct	Indirect	Description
LMA	6	R		Local Memory Address. The LMA will be the input value of the LMA incremented by the number of quadword transfers completed by the command.

RDMOREE (Read More Quadword From Egress) Command

After an Egress frame dispatch, the hardware stores the first N quadwords of the frame in the DataPool. RDMOREE is used to read more quadwords from the Egress Data Store. It uses three internal registers that are maintained by the Data Store coprocessor hardware (Dispatch DSUSel, Current Cell/Twin Address, and Next Quadword Address registers) to maintain the current position in the Egress Data Store and the Shared Memory Pool. During a RDMOREE, the hardware automatically reads the link pointer to update the Current/Cell Twin register when a twin boundary is crossed. The RDMOREE can be executed more than once if more quadwords are required.

Table 7-21. RDMOREE Input

		Operand Source		
Name	Size	Direct	Indirect	Description
NrOfQuadWord	2	Imm16(1..0)	GPR(1..0)	Defines the number of quadwords to be read. 01 1 quadword 10 2 quadwords 11 3 quadwords 00 4 quadwords
DSControl	2	Imm16(3..2)	Imm12(3..2)	Defines if the quadwords are read from DS0 or DS1: 00 Reads from the default DS 01 Reads from DS0 10 Reads from DS1 11 Reserved
Disp_DSUSel	1	R		Indicates the default DS chosen at Dispatch. 0 DS0 1 DS1
CCTA	19	R		Current Cell/Twin Address. Contains the twin source address in the Egress Data Store. This register is initalized at dispatch to point to the current twin fetched at dispatch.
NQWA	3	R		Next Quadword Address. The contents of this register indicates both the target quadword address in the Datapool as well as the source quadword of the twin buffer. This register is initalized at dispatch to point to the next QW after the data fetched at dispatch.

Table 7-22. RDMOREE Output

		Operand Source		
Name	Size	Direct	Indirect	Description
OK/KO (NP4GS3B (R2.0))	1	Flag		KO - An error occurred when reading the fourth quadword of a Twin buffer indicating that the Link Pointer contained in the data had a parity error. OK - Indicates that the link pointer had valid parity or that the link pointer wasn't read on this access.
CCTA	19	R		Current Cell/Twin Address. This register is updated by hardware. Executing RDMOREE again reads the next quadwords from Egress Data Store.
NQWA	3	R		Next QuadWord Address. This register is updated by hardware. Executing RDMOREE again causes the quadwords being read to be stored in the next locations in the DataPool.

RDMOREI (Read More Quadword From Ingress) Command

After an Ingress frame dispatch, the hardware stores the first N quadwords of the frame in the DataPool. RDMOREI is used to read more quadwords from the Ingress Data Store. It uses two internal registers that are maintained by the Data Store coprocessor hardware (Current Cell/Twin Address and Next Quadword Address registers) to maintain the current position in the Ingress Data Store and the Shared Memory Pool. During a RDMOREI, the hardware automatically reads the BCB to update the Current/Cell Twin register when a cell-boundary is crossed. RDMOREI can be executed more than once if more quadwords are required.

Table 7-23. RDMOREI Input

		Operand Source		
Name	Size	Direct	Indirect	Description
NrOfQuadWord	2	Imm16(1..0)	GPR(1..0)	Defines the number of quadwords to be read. 01 1 quadword 10 2 quadwords 11 3 quadwords 00 4 quadwords
CCTA	19	R		Current Cell/Twin Address. Contains the source ingress data buffer address in the Ingress Data Store. This register is initalized at dispatch to point to the next data buffer after the data fetched at dispatch.
NQWA	3	R		Next Quadword Address. The contents of this register indicates both the target quadword address in the Datapool as well as the source quadword of the ingress data buffer. The low two bits indicate the QW in the ingress data buffer, while all three bits are used to indicate the QW in the datapool. This register is initalized at dispatch to point to the next QW after the data fetched at dispatch.

Table 7-24. RDMOREI Output

		Operand Source		
Name	Size	Direct	Indirect	Description
CCTA	19	R		Current Cell/Twin Address. This register is updated by hardware. Executing RDMOREE again reads the next quadwords from Egress Data Store.
NQWA	3	R		Next QuadWord Address. This register is updated by hardware. Executing RDMOREE again causes the quadwords being read to be stored in the next locations in the DataPool.

LEASETWIN Command

This command leases a 19-bit twin address from the Egress pool of free twins.

Table 7-25. LEASETWIN Output

		Operand Source		
Name	Size	Direct	Indirect	Description
OK/KO (NP4GS3B (R2.0))	1	Flag		KO - No twins are currently available. OK - The command was successful.
CCTA	19	R		Current Cell/Twin Address. Contains the address of the newly leased twin.

EDIRTY (Update Egress Dirty Quadwords) Command

EDIRTY writes a quadword from the DataPool array to the Egress Data Store if the quadword has been modified since being loaded into the DataPool by a dispatch or a RDMOREE command. The Data Store coprocessor maintains a register (Dirty Quadword) which indicates when a quadword within the DataPool has been modified. The EDIRTY command uses the Dispatch DSU register to determine which egress Data Store (DS0, DS1, or both) must be updated. When the Current Cell/Twin Address is modified due to a RDMOREE command, all dirty bits are cleared, indicating no quadwords need to be written back to the egress Data Store.

Table 7-26. EDIRTY Inputs

		Operand Source		
Name	Size	Direct	Indirect	Description
CCTA	19	R		Current Cell/Twin Address. Contains the twin target address in the Egress Data Store.
NQWA	3	R		Next Quadword Address. The contents of this register indicates which QWs are considered for EDirty processing. NQWA Datapool QW Target Twin QW 0 7-0 7-0 1 0 0 2 1-0 1-0 3 2-0 2-0 4 3-0 3-0 5 4-0 4-0 6 5-0 5-0 7 6-0 6-0
DirtyQW	8	R		Indicates which quadwords need to be updated
DSControl	2	Imm16(3..2)	Imm12(3..2)	Defines if the quadwords are written to DS0, DS1 or both: 00 Writes to the default DSU. 01 Writes to DS0 10 Writes to DS1 11 Writes to DS0 and DS1
Disp_DSU	2	R		The default DSU, initialized at Dispatch.

Table 7-27. EDIRTY Output

		Operand Source		
Name	Size	Direct	Indirect	Description
DirtyQW	8	R		Dirty Quadwords. Bits which represent the data quadwords that were updated on this command will be reset to ‘0’.

IDIRTY (Update Ingress Dirty Quadwords) Command

IDIRTY writes a quadword from the DataPool array to the Ingress Data Store if the quadword has been modified since being loaded into the DataPool by a dispatch or a RDMOREI command. The Data Store coprocessor maintains a register (Dirty Quadword) which indicates when a quadword within the DataPool has been modified. The IDIRTY command uses the Next Quadword Address to determine which cell within the DataPool is represented by the Current Cell/Twin Address. When the Current Cell/Twin Address is modified due to a RDMOREI command, all dirty bits are cleared, indicating no quadwords need to be written back to the Ingress Data Store.

Table 7-28. IDIRTY Inputs

		Operand Source		
Name	Size	Direct	Indirect	Description
CCTA	19	R		Current Cell/Twin Address. The source address in the Ingress Data Store. Initially, this register is set during a dispatch.
NQWA	3	R		Next Quadword Address. The contents of this register indicates which QW are considered for action by the IDirty command. NQWA / Datapool QW / Target Ingress data buffer QW 0 / 7-4 / 3-0 1 / 0 / 0 2 / 1-0 / 1-0 3 / 2-0 / 2-0 4 / 3-0 / 3-0 5 / 4 / 0 6 / 5-4 / 1-0 7 / 6-4 / 2-0
DirtyQW	8	R		Indicates which quadwords need to be updated

Table 7-29. IDIRTY Output

		Operand Source		
Name	Size	Direct	Indirect	Description
DirtyQW	8	R		Dirty Quadwords. Bits which represent the data quadwords that were updated on this command will be reset to '0'.

7.4.3 Control Access Bus (CAB) Coprocessor

The CAB coprocessor provides interfaces to the CAB arbiter and the CAB for a thread. A thread must load the operands for a CAB access, such as CAB address and data. The protocol to access the CAB is then handled by the CAB interface coprocessor.

7.4.3.1 CAB Coprocessor Address Map

The CAB coprocessor has three scalar registers that are accessible to a thread and are shown in *Table 7-30*:

Table 7-30. CAB Coprocessor Address Map

Symbolic Register Name	Register Number	Size (bits)	Access	Description
CABStatus	x'00'	3	R	Status Register Bit 2 Busy Bit 1 0 = write access 1 = read access Bit 0 Arbitration granted
CABData	x'01'	32	R/W	Data to be written to CAB, or Data read from CAB
CABAddress	x'02'	32	W	Address used during last CAB access

7.4.3.2 CAB Access to NP4GS3 Structures

The Control Address Bus (CAB) is the NP4GS3's facility for accessing internal registers. The CAB is assessable via picocode and is used for both configuration and operational functions. CAB addresses consist of three fields and are defined as follows:

Table 7-31. CAB Address Field Definitions

Island ID	Structure Address	Element Address	Word Addr
5	23		4
32			

The first field, which is comprised of the five most significant bits of the address, selects one of 32 possible functional islands within the device. The correspondence between the encoded functional island value and the functional island name is shown in the *CAB Address, Functional Island Encoding* table below. Although some functional islands have Island_ID values, they are not accessed via the CAB. These functional islands are the Ingress Data Store, Egress Data Store, and Control Store. Structures in these functional islands are accessed via the Data Store coprocessor and the TSE.

Table 7-32. CAB Address, Functional Island Encoding

Island_ID	Functional Island Name	Notes
‘00000’	Ingress Data Store	1
‘00001’	Ingress PMM	
‘00010’	Ingress EDS	
‘00011’	Ingress SDM	
‘00100’	Embedded Processor Complex	
‘00101’	SPM	
‘00110’	Ingress Flow Control	
‘00111’	Embedded PowerPC	
‘01000’	Control Store	1
‘01111’	Reserved	
‘10000’	Egress Data Store	1
‘10001’	Egress PMM	
‘10010’	Egress EDS	
‘10011’	Egress SDM	
‘10100’	Configuration Registers	
‘10101’	DASL	
‘10110’	Egress Flow Control	
‘10111-11111’	Reserved	

1. These functional islands are not accessible via the CAB

The second portion of the CAB address consists of the next most significant 23 bits. This address field is segmented into structure address and element address. The number of bits used for each segment can vary from functional island to functional island. Some functional islands contain only a few large structures while others contain many small structures. The structure address addresses an array within the functional island while the element address addresses an element within the array. The data width of an element is variable and can exceed the 32-bit data width of the CAB.

The third portion of the CAB address consists of a 4-bit word address for selecting 32-bit segments of the element addressed. This address is necessary for moving structure elements wider than 32-bits across the CAB.

7.4.3.3 CAB Coprocessor Commands

The CAB Coprocessor provides the following commands:

Command	Opcode	Description
CABARB	0	CAB Arbitration. Used by a thread to gain access to the CAB. Once access is granted, that thread maintains control of the CAB until it releases the CAB. For more information, see *CABARB (CAB Arbitration) Command* on page 241
CABACCESS	1	Access CAB. Moves data onto or from the CAB and the attached CAB accessible registers. The source and destination within the DPPU are GPRs. For more information, see *CABACCESS Command* on page 242
CABPREEMPT	3	Preempt CAB. Used only by the GFH thread, it enables the GFH to gain control of the CAB for a single read/write access, even if the CAB has already been granted to another thread. For more information, see *CABPREEMPT Command* on page 242

CABARB (CAB Arbitration) Command

CABARB Requests to become a master on the CAB interface or requests to release the CAB after master status has been granted. CABARB does not cause a stall in the CLP even if run synchronously. The CAB coprocessor always indicates that CABARB was executed immediately, even if the arbiter did not grant the CAB interface to the coprocessor. The picocode must release ownership of the CAB interface when it is finished accessing the CAB or a lockout condition could occur for all non-preempt accesses.

Table 7-33. CABARB Input

		Operand Source		
Name	Size	Direct	Indirect	Description
Start_NEnd	1	Imm16(0)		1 Start arbitration 0 Release arbitration

CABACCESS Command

Performs a read or write access on the CAB. Before a CAB access can be performed, a CABARB command must have been issued to acquire ownership of the CAB interface.

Table 7-34. CABACCESS Input

		Operand Source		
Name	Size	Direct	Indirect	Description
Read_NWrite	1		Imm12(0)	1 Perform a CAB read 0 Perform a CAB write
Address	32		GPR(31..0)	The CAB address
CABData	32	R		Load for CAB write command

Table 7-35. CABACCESS Output

		Operand Source		
Name	Size	Direct	Indirect	Description
CABData	32	R		Set for CAB read command

CABPREEMPT Command

CABPREEMPT has the same input and output parameters as CABACCESS, except that a high-priority access to the CAB is performed. No CABARB command is required before CABPREEMPT. If any other coprocessor is CAB bus master (because it previously executed a CABARB), CABPREEMPT takes control of the CAB bus and executes the CAB read or write. After command execution, control of the CAB bus returns to the previous owner.

Use CABPREEMPT with care. For example, it might be used in debug mode when the GFH is single stepping one or more other coprocessors. To give a single step command, a CAB write must be executed using the CABREEMPT command because the coprocessor being single stepped may be executing a CABACCESS command and become CAB bus master. If the GFH used the CABACCESS command instead of CABPREEMPT, a deadlock would occur.

7.4.4 Enqueue Coprocessor

The Enqueue coprocessor manages the interface between a thread and the Completion Unit and manages the use of the FCBPage that is maintained in the Shared Memory Pool. Each thread has three FCBPage locations in which enqueue information about a frame may be maintained. Two of the pages improve the performance of the Completion Unit interface when they are alternated during consecutive enqueues. The picocode written for the thread does not differentiate between these two pages because hardware manages the swap. The thread uses the third page to allow the picocode to create new frames.

When a thread issues an enqueue command, the first FCBPage is marked as in-use. If the other FCBPage is available, the coprocessor is not considered “busy” and will not stall the CLP even if the command was issued synchronously. The Completion Unit fetches the FCBPage from the Shared Memory pool through the Enqueue coprocessor and provides its information to the EDS (either ingress or egress as indicated by the enqueue command). The FCBPage is then marked as free. If both FCBPages are marked in use, the Enqueue coprocessor is considered busy and stalls the CLP if a synchronous command initiated enqueue. To guarantee that FCBPage data is not corrupted, enqueue commands must always be synchronous.

Note: When an enqueue command is issued and the other location of the FCBPage becomes the “active” page, the data is not transferred between the FCBPages and should be considered uninitialized. This is an important consideration for picocode written to handle egress multicast frames.

7.4.4.1 Enqueue Coprocessor Address Map

Table 7-36. Enqueue Coprocessor Address Map

Name	Register Address	Size	Access	Description
Disp_Label	x‘00’	1	R/W	Indicates whether a label was dispatched to the completion unit for this frame. If the nolabel parameter is not passed during an ENQI or ENQE command, then this bit is used to determine if the enqueue will be done with or without a label. 0 Indicates that a label was not passed to the completion unit for this frame. 1 Indicates that a label was passed to the Completion Unit for this frame.
ActiveFCBPage1	x‘FC’	384	R/W	Active FCB Page for the current thread. This page is initialized at dispatch.
InActiveFCBPage1	x‘FD’	384	R/W	Inactive FCB Page for the current thread. This page is not initialized at dispatch. This array should never be written.
FCBPage2	x‘FE’	384	R/W	Alternate FCBPage

FCBPage Format

The FCBPage format varies based on dispatch parameters (ingress or egress frames) and access methods. The FCBPage can be accessed as a defined field, by word, or by quadword. The set of defined fields varies according to the ingress or egress dispatch parameter. Fields are mapped into locations of the Shared Memory Pool. Fields not defined as a multiple of eight bits are stored in the least significant bits (right-justified) of the byte location.

Table 7-37. Ingress FCBPage Description (Page 1 of 3)

Field	FCB Page Offset	Initialized by Dispatch Unit	Enqueue Info	Size (bits)	Description
SP	x'00'	Y	N	6	Source Port is the port identifier where this frame was received.
Abort	x'01'	Y	N	1	Aborted Frame indicates that the frame had been marked abort at the time of Dispatch.
GT	x'02'	Y	N	1	Guided Traffic indicator. This bit must be set to '1' when the frame is guided traffic.
FCInfo	x'03'	Y	Y	4	Flow Control color and frame drop information. See *Table 7-83: Flow Control Information Values* on page 279. Setting this field to x'F' disables flow control. Flow control must be disabled when enqueing to the GDQ, GFQ, or the discard queue.
WBC	x'04'	Y	N	15	Working byte count. This is the number of bytes available in the Ingress Data Store for this frame at the time it was dispatched.
FCBA	x'06'	Y	Y	11	Frame Control Block address for the frame dispatched
CurrentBuffer	x'08'	Y	Y	11	Ingress Data Store Buffer Address of the frame dispatched
TDMU	x'0C'	N	Y	2	Egress Target DMU. Encode is TDMU(1:0) DMU 00 A 01 B 10 C 11 D

Table 7-37. Ingress FCBPage Description (Page 2 of 3)

Field	FCB Page Offset	Initialized by Dispatch Unit	Enqueue Info	Size (bits)	Description
L3Stk/iDSU	x'0D'	N	Y	8/4	L3Stk (8-bit field). When iUCnMC = 0 (frame is multicast), this field contains the value of the DLL termination offset. The DLL termination offset is defined as the number of bytes starting at the beginning of the frame to the position one byte beyond the end of the data link layer. This value is based upon the encapsulation type. Typically, this is the same as the start of the Layer 3 protocol header, an exception would be for MPLS. iDSU (4-bit field). Data Store unit field in the frame header. Indicates where the frame should be stored when entering the egress side. When iUCnMC = 1 (frame is unicast). When set to 0, hardware determines the value of the Data Store unit field by using the value of the TDMU field and contents of the Ingress TDMU Data Storage Map Register (I_TDMU_DSU) (see *13.12 Ingress Target DMU Data Storage Map Register (I_TDMU_DSU)* on page 459).
PIB	x'0E'	N	Y	6	Point in Buffer. Prior to enqueue, indicates location of the first byte of the frame to be sent across the switch interface
TOS	x'0F'	Y	Y	8	If the frame is an IP frame these bits will be the TOS field in the IP Header, otherwise they will be initialized to 0's. For differentiated services, the following subfields are defined: 7:5 AF Class. Bits are used by the flow control hardware when addressing the Transmit Probability table. 4:2 Drop precedence 1:0 CU (currently unused).
TB	x'10'	N	Y	16	Target Blade Vector or Target Blade Address. When in 16-blade mode these 16 bits are used as a target blade vector for multicast frames. In all other modes and for UC frames this is a target blade address. As a target blade vector, bit 15 corresponds to target blade address 0, that is, TB(0:15) In 64-blade mode, valid unicast target blade addresses are 0 through 63, multicast addresses are 512 to 65535.
iUCnMC	x'12'	N	Y	1	Unicast/Multicast indicator 0 Multicast frame 1 Unicast frame
Priority_SF	x'13'	N	Y	2	Priority and special field indicators defined as: Bit Description 0 Special Field. Indicates enqueues to the discard queue, GDQ, or GCQ. This is normally set by hardware when the QCLASS is used in the ENQI command. 1 Priority. Ingress scheduler priority indicates the user priority assigned to the frame. High priority is indicated by a value of 0.
LID/MID	x'14'	N	Y	21/17	Lookup ID (21-bit field). Ingress picocode uses to pass information to the egress picocode. Used when iUCnMC = 1 (frame is unicast). Multicast ID (17-bit field). Ingress picocode uses to pass information to the egress picocode. Used when iUCnMC = 0 (frame is multicast).
VLANHdr	x'18'	N	Y	16	VLAN Header. This is the Tag Control Information field defined in the IEEE 802.3 standard.

Table 7-37. Ingress FCBPage Description (Page 3 of 3)

Field	FCB Page Offset	Initialized by Dispatch Unit	Enqueue Info	Size (bits)	Description
Ins_OvlVLAN	x'1A'	N	Y	2	Insert or overlay VLAN. Indicates if the VLAN header provided in the VLANHdr scalar register is inserted or overlays an existing VLAN Tag. Bit Description 0 Overlay VLAN 1 Insert VLAN
FHF	x'1B'	N	Y	4	Frame Header Format. 4-bit field used by hardware and set up by picocode. Hardware Classifier uses this value on the egress side to determine the starting instruction address for the frame.
FHE	x'1C'	N	Y	32	Frame header extension. A 4-byte field whose contents are defined by picocode.
CounterControl	x'28'	N	Y	14	Passed to Flow Control for delayed counter manager functions. Bits Description 13 When set to 1 enables counter operation for this enqueue. Counter updates on an enqueue work only when the target is a target blade. Counter updates do not occur when enqueueing to the GDQ, GFQ, or the discard queue. 12 Add/Increment 11:8 Counter Number 7:0 Counter Definition Table Index
CounterData	x'2A'	N	Y	16	Data passed to Ingress Flow Control for delayed counter manager add functions
CounterBlockIndex	x'2C'	N	Y	20	Block Index passed to Ingress Flow Control for delayed counter manager functions

Table 7-38. Egress FCBPage Description (Page 1 of 4)

Field	FCB Page Offset	Initialized by Dispatch Unit	Size (bits)	Description
SB	'00'	Y	6	Source Blade
eUCMC	'01'	Y	3	Egress Unicast/Multicast bits 000 Unicast 001 First Multicast 010 Middle Multicast 011 Last Multicast 100 Unicast Static Frame enqueue 101 First Multicast Static Frame 110 Middle Multicast Static Frame 111 Last Multicast Static Frame
DSUSel	'02'	Y	1	Indicates which DSU is in use by the Dispatch Unit and Read More instructions. 0 DS0 1 DS1
FCInfo	'03'	Y	4	Flow control color information pulled from the frame header by the hardware classifier. See *Table 7-83: Flow Control Information Values* on page 279.
BCI	'04'	Y	20	Byte count indicator passed from a queue (GR0, GR1, GB0, GB1, GPQ, GTQ, GFQ) to the FCBPage. Indicates starting byte location within the first twin, number of data buffers, and ending byte location within the last twin. Bit Description 19:14 Starting Byte 13:6 Number of Data Buffers (Weight) 5:0 Ending Byte Byte numbering within the data buffers starts at 0 and goes to 63.
CurrTwin	'08'	Y	20	At dispatch, indicates the first twin address of the frame
Type	'0C'	Y	3	Type indicates frame type and data store used. Type (2:1) 00 Frame 01 Reserved 10 Reserved 11 Abort Type (0) for GTQ, GPQ 0 DSU0 1 DSU1 Type(0) for GR0, GB0 0 DSU0 1 Both DSU0 and 1 Type(0) GR1, GB1 0 DSU1 1 Both DSU0 and 1
DSU	'0D'	Y	2	Indicates in which DSU(s) the data for this frame is stored. Value is DSU(1:0). Value Description 00 Reserved 01 Stored in DSU 0 10 Stored in DSU 1 11 Stored in both DSU 0 and 1

Table 7-38. Egress FCBPage Description (Page 2 of 4)

Field	FCB Page Offset	Initialized by Dispatch Unit	Size (bits)	Description
QHD	'0E'	N	1	Twin Header Qualifier. Indicates type of twin pointed to by CurrTwin. Used for egress frame alteration. 0 The twin pointed to by the CurrTwin is a data twin 1 The twin pointed to by the CurrTwin is a header twin
OW	'0F'	N	4	Orphan twin weight. Number of twins orphaned by frame alteration actions. When this field is greater than 0, the DATAFirstTwin scalar must be loaded with the location of the first Data Twin. When this field is 0, the EtypeAct and EtypeValue scalar registers can be loaded for insert and overlay Ethertype frame alterations.
QID	'10'	N	20	Queue identifier. The format of the QID is determined by QID(19:18) as follows: QID(19:18) 00 and Scheduler is active, the queue is a Flow QCB QID(10:0) Flow QCBAddress 00 and Scheduler disabled, the queue is a indicates the Target Port where: QID (6) Priority QID (5:0) Target Port ID 11 G queue identifier, where QID(17:0) indicates the queue as: QID (17:0) queue 000 GR0 001 GR1 010 GB0 011 GB1 100 GFQ 101 GTQ 110 GPQ 111 Discard
DATAFirstTwin	'14'	N	19	Address of frame's first data twin. Valid when OW is not 0.
EtypeAct	'15'	N	3	The field is defined as Bits(2:0) Definition 000 Etype value is invalid 001 Etype value is valid and is used when SA/DAinsert/overlay hardware assisted frame alteration is active to insert/overlay the Etype field of the frame being processed. 010-111 Reserved
EtypeValue	'16'	N	16	Ethertype value used in insert / overlay egress frame alteration
SAPtr	'18'	N	10	Source Address Pointer for egress frame alteration. Indicates the SA Array address used by the E-PMM to locate the source address for egress frame alterations. Valid ranges are 0 - 63.
DA47_32	'1A'	N	16	Destination address bits (47:32) used for frame alteration SA/DA insert or overlay actions.
DA31_0	'1C'	N	32	Destination address bits (31:0) used for frame alteration SA/DA insert or overlay actions.

Table 7-38. Egress FCBPage Description (Page 3 of 4)

Field	FCB Page Offset	Initialized by Dispatch Unit	Size (bits)	Description
SAInsOvl	'20'	N	2	Egress Frame alteration controls for overlay of SA, DA, and Ethertype (when EtypeAct is set to "001") Bit Description 1 Indicates insert (field value 10) 0 Indicates overlay (field value 01) Both bits may not be set to 1. (11 = invalid and 00 = no action)
VLAN_MPLS_HWA	'21'	N	2	Hardware assist for deleting VLAN Tags, deleting MPLS Labels and performing MPLS Label swap. The field is defined as follows: 00 no action 01 MPLS Label Delete. 10 VLAN Tag Delete 11 MPLS Label Swap (NP4GS3B (R2.0) only) The location of the VLAN Tag is fixed at offset 12. The location of the MPLS label is determined by the value of the DLL stake field. The MPLS Label Swap function modifies the label stack entry (4 bytes) as follows: - The 20-bit label field is replaced by the contents of the DA(47:28) field - The stack entry Exp and S fields are unchanged. - The stack entry TTL field is decremented.
CRCAction	'22'	N	2	Egress frame alteration controls for modifying the CRC of an Ethernet frame. Value Description 00 No operation 01 Reserved 10 Append CRC 11 Overlay CRC
DLLStake	'23'	N	6	The value of the DLL termination offset. The DLL termination offset is defined as the number of bytes starting at the beginning of the frame to the position one byte beyond the end of the data link layer. This value is based upon the encapsulation type. Typically, this is the same as the start of the Layer 3 protocol header, an exception would be for MPLS.
TTLAssist	'24'	N	2	Egress frame alteration controls for modifying the time to live field in IP headers or the next hop field in IPX headers. Value is TTLAssist(1:0) below: Value Description 00 Disabled 01 IPv4, decrement TTL 10 IPX, increment hop count 11 Reserved

Table 7-38. Egress FCBPage Description (Page 4 of 4)

Field	FCB Page Offset	Initialized by Dispatch Unit	Size (bits)	Description
CounterControl	'28'	N	14	Passed to Flow Control for delayed counter manager functions Bits Description 13 When set to 1 enables counter operation for this enqueue. Counter updates on an enqueue work only when the target is a target port or flow queue. Counter updates do not occur when enqueing to the GRx, GBx, GFQ, GPQ, GTQ or E-GDQ. Counter updates are supported for the Discard Port (PortID = 41) and the Wrap Ports (PortID = 40, 42) 12 Add/$\overline{\text{Increment}}$ 11:8 Counter Number 7:0 Counter Definition Table Index
CounterData	'2A'	N	16	Data passed to Egress Flow Control for delayed counter manager add functions.
CounterBlockIndex	'2C'	N	20	Block Index passed to Egress Flow Control for delayed counter manager functions

FCBPage Initialization During Dispatch

During a dispatch to a thread, the Hardware Classifier and the Dispatch unit provide information about the frame being dispatched that is used to initialize some of the fields within the FCBPage. Values initialized at the time of dispatch are indicated in *Table 7-37* and *Table 7-38*. Values that are not indicated as initialized at dispatch are initialized to '0' for the "active" FCBPage.

7.4.4.2 Enqueue Coprocessor Commands

The following commands are supported by the Enqueue coprocessor:

Command	Opcode	Description
ENQE	0	Enqueue Egress. Enqueues to the Egress EDS via the Completion Unit. For more information, see *ENQE (Enqueue Egress) Command* on page 251.
ENQI	1	Enqueue Ingress. Enqueues to the Ingress EDS via the Completion Unit. For more information, see *ENQI (Enqueue Ingress) Command* on page 253.
ENQCLR	2	Enqueue Clear. Clears (sets all fields to zero in) the specified FCBPage. For more information, see *ENQCLR (Enqueue Clear) Command* on page 255.
Release_Label (NP4GS3B (R2.0))	3	Release Label. Releases the label in the Completion Unit for this frame. For more information, see *RELEASE_LABEL Command* on page 256.

ENQE (Enqueue Egress) Command

ENQE enqueues frames to the Egress target queues.

Table 7-39. ENQE Target Queues ENQE command enqueues a frame in one of these Egress target queues

Target Queue	Description	Note
Target Port/Flow Queues	If the Scheduler is disabled, enqueued frames are transmitted on target ports 0-39, and logical ports 40-42. If the Scheduler is enabled, enqueued frames are enqueued into the flow queues.	
GR0	Enqueued frames are destined for any GDH (or the GFH when it is enabled for data frame processing). A unicast frame must be stored in DS0 when queue GR0 is used. A multicast frame must always be stored in both DS0 and DS1.	1
GR1	Enqueued frames are destined for any GDH (or the GFH when it is enabled for data frame processing). A unicast frame must be stored in DS1 when queue GR1 is used. A multicast frame must always be stored in both DS0 and DS1.	1
GB0	Same as GR0, but treated by the Dispatch Unit as lower priority	1
GB1	Same as GR1, but treated by the Dispatch Unit as lower priority	1
GFQ	Enqueued frames in this queue are destined for the GFH	1
GTQ	Enqueued frames in this queue are destined for the GTH	1
GPQ	Enqueued frames in the queue are destined for the embedded PowerPC	1
Discard Queue (E-GDQ)	Enqueued frames in this queue are discarded, which involves freeing E-DS space (twins). Frames are only discarded when the MCCA (Multicast Counter Address) enqueue parameter equals zero, or when the Multicast Counter itself has the value 1.	

1. When enqueuing to the GR0, GR1, GB0, GB1, GFQ, GTQ, or the GPQ it is recommended to check the depth of the queue. A dead lock can occur if an attempt is made to enqueue to a full queue. When the queue is full, the enqueue should be re-directed to the discard queue, an action performed by code, and the event reported either via a count or guided traffic.

The QID field in the FCBPage selects the Egress target queue. *Table 7-40* shows the coding of the QID for this selection. ENQE takes a QueueClass as a parameter, and some values of QueueClass automatically set some bits in the QID field to a predefined value.

Table 7-40. Egress Target Queue Selection Coding

Scheduler Enabled?	QID(19-18)	Target Queue Class	Queue Address	Priority	Target Queue
Yes	00	Flow Queue	QID(10..0)	-	Flow Queue
No	00	Target Port Queue	QID(5..0) (TPQID)	QID(6) (TPPri)	0-39 Ports 40 Wrap to Ingress GFQ 41 Discard (DPQ) 42 Wrap to Ingress GDQ
-	11	GQueue	QID(2..0) (GQID)	-	000 GR0 001 GR1 010 GB0 011 GB1 100 GFQ 101 GTQ 110 GPQ 111 Discard (E-GDQ)

When a frame is enqueued, the parameters from the FCBPage parameters are extracted and passed to the Egress Target Queue.

Table 7-41. Egress Target Queue Parameters

Queue Type	Queue Select	Enqueue Parameters
Target Port/Flow Queue	QID	QID, BCI, QHD, OW, DATAFirstTwin, SB, CurrTwin, MCCA, MPLS_VLANDel, SAInsOvl, CRCAction, L3Stake, TTLAssist, DSU, SAPtr, DA, FCInfo, CounterControl, CounterData, CounterBlockIndex
GR0, GR1, GB0, GB1, GFQ, GTQ, GPQ	QID	CurrTwin, Type, BCI, MCCA, CounterControl, CounterData, CounterBlockIndex
Discard (E-GDQ)	QID	CurrTwin, Type (see *Table 7-42*), BCI, MCCA

Table 7-42. Type Field for Discard Queue

Type	Definition
001	Discard DS0
010	Discard DS1
Others	Reserved

ENQE takes three parameters: the QueueClass, a NoLabel flag, and the FCBPage. According to the Queue Class parameter, bits 19, 18, and 5..0 in the QID field of the FCBPage are changed by the coprocessor according to *Table 7-44*. Like ENQI, ENQE does not modify the FCBPage.

Table 7-43. ENQE Command Input

		Operand Source		
Name	Size	Direct	Indirect	Description
QueueClass	5	Imm16(4..0)	GPR(4..0)	Egress Queue Class as defined in *Table 7-44*.
NoLabel	1	Imm16(5)	Imm12(5)	0 The CU will use a label if one was dispatched with this frame. This is determined by the status of the Disp_Label register. 1 The Completion Unit will not use a Label for this enqueue. This enqueue is directly executed and is not part of the frame sequence maintenance.
FCBPageID	2	Imm16(7..6)	Imm12(7..6)	00 Active FCBPage is enqueued. 10 FCBPage 2 is enqueued.

Table 7-44. Egress Queue Class Definitions

QueueClass	QID19	QID18	QID2	QID1	QID0	Target Queue	Notes
0	-	-	-	-	-	Reserved	
1	0	0	-	-	-	Port/Flow queue	
2	0	0	QID(5..0) = 40			Wrap GFQ queue	4
3	0	0	QID(5..0) = 41			Discard queue (DPQ)	
4	0	0	QID(5..0) = 42			Wrap Frame queue	
5	1	1	0	0	S	GRx queue	1
6	1	1	0	1	S	GBx queue	1
7	1	1	1	0	0	GFQ	
8	1	1	1	0	1	GTQ	
9	1	1	1	1	0	GPQ	
10	1	1	1	1	1	Discard queue (GDQ)	3
15	-	-	-	-	-	Any queue	2

1. The ENQE instruction may automatically select the appropriate Data Store or queue, depending on the DSUSel bit.
2. Queue class 15 does not modify any QID bits and allows picocode full control of the target queue.
3. The Type field is modified: bit 2 is set to 0 and the DSU bits are copied to bits 0 and 1 of the Type field.
4. When using Queue Class 2, 3, or 4 and the scheduler is enabled, it is the responsibility of the picocode to insure that QCB 40, 41, and 42 are initialized for the Wrap GRQ (40), the Discard port (41), and wrap data queue (42).

Note: '-' - the field is not modified by the enqueue instruction
S - the value of the DSUSel bit in the FCBPage

ENQI (Enqueue Ingress) Command

ENQI enqueues frames to the Ingress target queues.

Table 7-45. ENQI Target Queues

Target Queue	Description
Ingress Multicast queue Priorities 0/1	Enqueued frames are treated as multicast frames. Guided frames must be enqueued in a multicast queue, even when their destination is a single port.
Ingress TP queue Priorities 0/1	Enqueued frames are treated as unicast frames. There are a total of 512 TDMU queues: 256 high priority (priority 0) and 256 low priority.
Ingress Discard queue Priorities 0/1	Enqueued frames are discarded, which involves freeing Ingress buffer space (BCBs and FCBs). Discarding frames on Ingress consumes ingress scheduler slots, i.e., frames are discarded at 58 bytes per slot. The FCBPage's target blade field (TB) must be set to 0.
Ingress GDQ	Enqueued frames are destined for any GDH (or GFH when enabled for data frame processing).
Ingress GFQ	Enqueued frames are destined for the GFH.

Ingress target queues are selected by means of three fields that are part of the FCBPage: iUCnMC, Priority_SF, and TDMU. *Table 7-46* shows the coding of this selection.

Table 7-46. Ingress Target Queue Selection Coding

iUCnMC	Priority	SF	TDMU	Target Queue
0	0	0	-	Ingress Multicast queue - priority 0
0	1	0	-	Ingress Multicast queue - priority 1
1	0	0	0 - 3	Ingress TP queue - priority 0
1	1	0	0 - 3	Ingress TP queue - priority 1
1	0	1	0	Ingress Discard queue - priority 0
1	1	1	0	Ingress Discard queue - priority 1
1	x	1	2	Ingress GDQ
1	x	1	3	Ingress GFQ

When a frame is enqueued the parameters from the FCBPage are extracted and passed to the Ingress Target Queue. *Table 7-47* shows the parameters that are passed to the Ingress EDS.

Table 7-47. Ingress Target Queue FCBPage Parameters

Frame Type	Parameters
UC Ethernet	FCBA, CounterControl, CounterData, CounterBlockIndex, TB, TDMU, FCInfo, Priority_SF, iUCnMC, LID, iDSU, FHF, FHE, VLANHdr, PIB, Ins_OvlVLAN
MC Ethernet	FCBA, CounterControl, CounterData, CounterBlockIndex, TB, Priority_SF, iUCnMC, FCInfo, MID, L3Stk, FHF, FHE, VLANHdr, PIB, Ins_OvlVLAN

ENQI takes three parameters: the QueueClass, a NoLabel flag, and a FCBPage. According to the Queue-Class parameter, the Priority_SF and TDMU fields in the FCBPage are modified by the Enqueue coprocessor according to *Table 7-49* when passed to the Ingress EDS. For example, to enqueue a unicast frame for transmission, the picocode prepares the FCBPage, including the Priority and TP fields and invokes ENQI with QueueClass set to 5.

Table 7-48. ENQI Command Input

		Operand Source		
Name	Size	Direct	Indirect	Description
QueueClass	5	Imm16(4..0)	GPR(4..0)	*Table 7-49: Ingress-Queue Class Definition* on page 255
NoLabel	1	Imm16(5)	Imm12(5)	0 The CU will use a label if one was dispatched with this frame. This is determined by the status of the Disp_Label register. 1 The Completion Unit will not use a Label for this enqueue. This enqueue is directly executed and is not part of the frame sequence maintenance.
FCBPageID	2	Imm16(7..6)	Imm12(7..6)	00 Active FCBPage 1 is enqueued. 10 FCBPage 2 is enqueued.

Table 7-49. Ingress-Queue Class Definition

Queue Class	Symbolic Name	iUCnMC	Priority	SF	TDMU	Target Queue
0	DQ	1	-	1	0	Discard queue. Picocode must set the Priority field. TB field must be set to 0 by the picocode. FCInfo field must be set to x'F'.
2	I-GDQ	1	1	1	2	GDH queue. FCInfo field must be set to x'F'.
4	GFQ	1	1	1	3	GFH queue. FCInfo field must be set to x'F'.
5	TXQ	-	-	0	-	Multicast queue or TDMU QCB queues (transmission queues). Picocode must set iUCnMC and TP fields.
7	ANYQ	-	-	-	-	Any queue. Picocode must set iUCnMC, Priority, SF and TP fields.
Note: A '-' means the FCBPage field is not modified by the ENQI command when passed to the Ingress-EDS.						

ENQI does not modify the FCBPage. For example, if the QueueClass parameter is set to TXQ, the SF field is set to '0'. This means that in the SF field received by the Completion Unit and passed to the Ingress-EDS is modified to '0'. The SF field in the FCBPage is not modified.

ENQCLR (Enqueue Clear) Command

ENQCLR takes one parameter, the FCBPage, and fills the entire FCBPage register with zeros.

Table 7-50. ENQCLR Command Input

		Operand Source		
Name	Size	Direct	Indirect	Description
FCBPageID	2	Imm16(7..6)	Imm12(7..6)	Indicates which FCB Is to be cleared by the command. 00 Active FCBPage is cleared. 10 FCBPage 2 is cleared.

Table 7-51. ENQCLR Output

		Operand Source		
Name	Size	Direct	Indirect	Description
FCBPage	384	Array		The FCBPage array indicated by the input FCBPageID will be reset to all '0's.

RELEASE_LABEL Command

This command (available in NP4GS3B (R2.0)) releases the label in the Completion Unit for this frame. This command has no inputs.

Table 7-52. RELEASE_LABEL Output

		Operand Source		
Name	Size	Direct	Indirect	Description
Disp_Label	1	R		The Disp_Label register is reset on the execution of the release label command.

7.4.5 Checksum Coprocessor

The checksum coprocessor generates checksums using the algorithm found in the IETF Network Working Group RFC 1071 “Computing the Internet Checksum” (available at http://www.ietf.org). As such, it performs its checksum operation on halfword data with a halfword checksum result.

7.4.5.1 Checksum Coprocessor Address Map

Table 7-53. Checksum Coprocessor Address Map

Name	Register (Array) Number	Access	Size (Bits)	Description
ChkSum_Stat	x‘00’	R	2	Status of Checksum coprocessor Bits Description 1 Insufficient Indicator (if set to 1) 0 Bad Checksum (if set to 1)
ChkSum_Acc	x‘01’	R/W	16	When writing this register, the value is a checksum. When reading this register, the value is a Header Checksum (the one’s complement of a checksum).
ChkSum_Stake	x‘02’	R/W	10	Pointer into Data Store Coprocessor Arrays where Checksum is to be performed. Bits Description 9:8 Data Store Coprocessor Array Number 7:0 Byte Offset into the Array
ChkSum_Length	x‘03’	R/W	8	Working Length remaining in the Checksum calculation

7.4.5.2 Checksum Coprocessor Commands

Data for the Checksum coprocessor must be in one of the Data Store coprocessor's arrays. The commands to the Checksum coprocessor include:

Command	Opcode	Description
GENGEN	0	Generate Checksum. Generates a checksum over a data block with a specified length. Options of this command include initiating a new checksum operation or continuing a checksum where a previous checksum has left off. For more information, see *GENGEN/GENGENX Commands* on page 258.
GENGENX	4	Generate Checksum with Cell Header Skip. For more information, see *GENGEN/GENGENX Commands* on page 258.
GENIP	1	Generate IP Checksum. For more information, see *GENIP/GENIPX Commands* on page 259.
GENIPX	5	Generate IP Checksum with Cell Header Skip. For more information, see *GENIP/GENIPX Commands* on page 259.
CHKGEN	2	Check Checksum. Checks a checksum over a data block with a specified length. Options of this command include initiating a new checksum operation or continuing a checksum where a previous checksum has left off. For more information, see *CHKGEN/CHKGENX Commands* on page 259.
CHKGENX	6	Check Checksum with Cell Header Skip. For more information, see *CHKGEN/CHKGENX Commands* on page 259.
CHKIP	3	Check IP Checksum. For more information, see *CHKIP/CHKIPX Commands* on page 260.
CHKIPX	7	Check IP Checksum with Cell Header Skip. For more information, see *CHKIP/CHKIPX Commands* on page 260.

When an IP is indicated, the starting location (i.e., stake) for the Layer 3 header is passed. The hardware determines the length of the IP header from the header length field and loads this value into the Length scalar register. When generating the checksum, a value of zero is substituted for the halfword that contains the current checksum.

When Cell Header Skip is indicated, the cell header in the egress frame is skipped in checksum operations. See *The DataPool for Egress Frames* on page 227 for more details of Cell Header Skip.

GENGEN/GENGENX Commands

Table 7-54. GENGEN/GENGENX Command Inputs

		Operand Source		
Name	Size	Direct	Indirect	Description
Load New Stake	1	Imm(6)	Imm(6)	Indicates: 1 Stake value is passed in the command. 0 Stake value is in ChkSum_Stake.
Clear Accumulation	1	Imm(5)	Imm(5)	ChkSum_Acc contains the seed for the checksum operation. The value in this register indicates whether to use or clear the data in ChkSum_Acc. 0 Use data 1 Clear ChkSum_Acc
Stake Argument	10	Imm(1:0,15:8)	Imm(1:0) GPR(23:16)	The new stake value to be used for the checksum operation if the Load New Stake argument is '1'. The stake argument is comprised of two parts. The first (Imm1:0) is the Data Store coprocessor Array number. The second(Imm(15:8) or GPR(23:16)) is the byte offset within the array.
ChkSum_Stake	10	R		The stake value to be used for the checksum operation if the Load New Stake argument is '0'.
ChkSum_Acc	16	R		Contains the seed for the next checksum operation if the "Clear Accumulation" argument is a '0'. (Otherwise there is no data in ChkSum_Acc).
ChkSum_Length	8	R		The number of halfwords to read when calculating checksum

Table 7-55. GENGEN/GENGENX/GENIP/GENIPX Command Outputs

		Operand Source		
Name	Size	Direct	Indirect	Description
Return Code	1	CPEI Signal		0 KO, operation failed because there was not enough data in the DataPool 1 OK, operation completed successfully.
ChkSum_Stat	2	R		Status of Checksum coprocessor Bits Description 1 Insufficient data in DataPool 0 Bad Checksum
ChkSum_Stake	10	R		Stake Register. Points to the halfword of data following the last halfword used in the checksum command.
ChkSum_Acc	16	R		The seed for the next checksum operation. Contains the resulting checksum if the Return Code is OK.

GENIP/GENIPX Commands

Table 7-56. GENIP/GENIPX Command Inputs

		Operand Source		
Name	Size	Direct	Indirect	Description
Load New Stake	1	Imm(6)	Imm(6)	Indicates: 1 Stake value is passed in the command. 0 Stake value is in ChkSum_Stake.
Clear Accumulation	1	Imm(5)	Imm(5)	ChkSum_Acc contains the seed for the checksum operation. The value in this register indicates whether or not to use or clear the data in ChkSum_Acc. 0 Use data 1 Clear ChkSum_Acc
Clear IP Count	1	Imm(4)	Imm(4)	IP Count clear control. 0 Continue with current count in the Checksum Length register 1 Clear counter and load with value in IP length field.
Stake Argument	10	Imm(1:0,15:8)	Imm(1:0) GPR(23:16)	The new stake value to be used for the checksum operation if the Load New Stake argument is '1'. The stake argument is comprised of two parts. The first (Imm1:0) is the Data Store coprocessor Array number. The second(Imm(15:8) or GPR(23:16)) is the byte offset within the array.
ChkSum_Stake	10	R		The stake value to be used for the checksum operation if the Load New Stake argument is '0'.
ChkSum_Acc	16	R		Contains the seed for the next checksum operation if the "Clear Accumulation" argument is a '0' (otherwise there is no data in ChkSum_Acc).

For GENIP/GENIPX Command Outputs, see *Table 7-55: GENGEN/GENGENX/GENIP/GENIPX Command Outputs* on page 258.

CHKGEN/CHKGENX Commands

Table 7-57. CHKGEN/CHKGENX Command Inputs

		Operand Source		
Name	Size	Direct	Indirect	Description
Load New Stake	1	Imm(6)	Imm(6)	Indicates: 1 Stake value is passed in the command. 0 Stake value is in ChkSum_Stake.
Stake Argument	10	Imm(1:0,15:8)	Imm(1:0) GPR(23:16)	The new stake value to be used for the checksum operation if the Load New Stake argument is '1'. The stake argument is comprised of two parts. The first (Imm1:0) is the Data Store coprocessor Array number. The second(Imm(15:8) or GPR(23:16)) is the byte offset within the array.
ChkSum_Stake	10	R		The stake value to be used for the checksum operation if the Load New Stake argument is '0'.
ChkSum_Acc	16	R		This is the checksum to be verified.
ChkSum_Length	8	R		The number of halfwords to read when calculating the checksum.

Table 7-58. CHKGEN/CHKGENX/CHKIP/CHKIPX Command Outputs

		Operand Source		
Name	Size	Direct	Indirect	Description
Return Code	1	CPEI Signal		0 KO, operation failed. Check status register for reason. 1 OK, operation completed successfully.
ChkSum_Stat	2	R		Status of Checksum coprocessor Bits Description 1 Insufficient data in DataPool 0 Bad Checksum
ChkSum_Stake	10	R		Stake Register. Points to the halfword of data following the last halfword used in the checksum command.
ChkSum_Acc	16	R		The seed for the next checksum operation. If equal to 0 the checksum was correct.

CHKIP/CHKIPX Commands

Table 7-59. CHKIP/CHKIPX Command Inputs

		Operand Source		
Name	Size	Direct	Indirect	Description
Load New Stake	1	Imm(6)	Imm(6)	Indicates: 1 Stake value is passed in the command. 0 Stake value is in ChkSum_Stake.
Clear IP Count	1	Imm(4)	Imm(4)	IP Count clear control. 0 Continue with current count in the Checksum Length register. 1 Clear counter and load with value in IP length field.
Stake Argument	10	Imm(1:0,15:8)	Imm(1:0) GPR(23:16)	The new stake value to be used for the checksum operation if the Load New Stake argument is '1'. The stake argument is comprised of two parts. The first (Imm1:0) is the Data Store coprocessor Array number. The second(Imm(15:8) or GPR(23:16)) is the byte offset within the array.
ChkSum_Stake	10	R		The stake value to be used for the checksum operation if the Load New Stake argument is '0'.
ChkSum_Acc	16	R		This is the checksum to be verified.

For CHKIP/CHKIPX Command Outputs, see *Table 7-58: CHKGEN/CHKGENX/CHKIP/CHKIPX Command Outputs* on page 260.

Results of the commands are found in ChkSum_Acc, ChkSum_Stake, and the 1-bit return code to the CLP. ChkSum_Acc contains the result of the checksum calculation. ChkSum_Stake contains the byte location following the last halfword included in the checksum. The return code indicates the operation completed successfully or was verified. The Status register may need to be read to determine the status on a bad return code.

7.4.6 String Copy Coprocessor

The String Copy coprocessor extends the DPPU's capabilities to move blocks of data without tying up the CLP. The data is moved within the Shared Memory Pool and can start and end on any byte boundary within a defined array.

7.4.6.1 String Copy Coprocessor Address Map

Table 7-60. String Copy Coprocessor Address Map

Name	Register Number	Size (Bits)	Access	Description
StrCpy_SAddr	x'00'	14	R/W	The source address for the data to be copied: Bit Description 14 Cell header skip access mode 13:10 Coprocessor Number 9:8 Array Number from coprocessor address maps 7:0 Byte Offset within the Array
StrCpy_DAddr	x'01'	14	R/W	The destination address for the data to be copied: Bit Description 14 Cell header skip access mode 13:10 Coprocessor Number 9:8 Array Number from coprocessor address maps 7:0 Byte Offset within the Array
StrCpy_ByteCnt	x'02'	8	R	The number of bytes remaining to be moved. This is a working register. Once the coprocessor starts, this register will no longer be valid (it will show the number of bytes remaining).

7.4.6.2 String Copy Coprocessor Commands

Command	Opcode	Description
STRCOPY	0	For more information, see *StrCopy (String Copy) Command* on page 261

StrCopy (String Copy) Command

StrCopy moves multiple bytes of data between arrays in the Shared Memory Pool. The CLP passes the starting byte locations of the source and destination data blocks, and the number of bytes to move.

Table 7-61. StrCopy Command Input

		Operand Source		
Name	Size	Direct	Indirect	Description
StrCpy_SAddr	14	R		Source Address. See *Table 7-60: String Copy Coprocessor Address Map* on page 261
StrCpy_DAddr	14	R		Destination Address. See *Table 7-60: String Copy Coprocessor Address Map* on page 261
NumBytes	8	Imm(7:0)	GPR(7:0)	Number of Bytes to transfer

Table 7-62. StrCopy Command Output

		Operand Source		
Name	Size	Direct	Indirect	Description
StrCpy_SAddr	14	R		Source Address. The offset field of the source address will be incremented by the number of bytes transferred.
StrCpy_DAddr	14	R		Destination Address. The offset field of the destination address will be incremented by the number of bytes transferred.
NumBytes	8	R		This field is 0.

7.4.7 Policy Coprocessor

The Policy coprocessor provides an interface to the Policy Manager for threads. A thread requests an update to the “color” of a frame through this interface. Frame color is part of the network processor's configurable flow control mechanism which determines what actions may be taken on the frame. A thread must wait until the Policy Manager, via the Policy coprocessor, returns a result.

7.4.7.1 Policy Coprocessor Address Map

Table 7-63. Policy Coprocessor Address Map

Name	Register Number	Size (bits)	Access	Description
PolColor	x‘00’	2	R/W	Both the color that is passed to the Policy Manager and the result color that is passed back from the Policy Manager
PolPktLen	x‘01’	16	R/W	The packet length sent to the Policy Manager
PolCBA	x‘02’	20	R	A value of the Policy Control Block Address that was found in a leaf after the frame has been classified and a search was performed

7.4.7.2 Policy Coprocessor Commands

Command	Opcode	Description
POLACCESS	0	For more information, see *PolAccess (Access Policy Manager) Command* on page 262

PolAccess (Access Policy Manager) Command

PolAccess requests that the Policy Manager accesses the policy control block for the flow that this frame is a member of. Operands include the policy control block address, the length of the packet (usually the IP packet length), and the color currently assigned to the frame. The result returned is a new frame color.

Table 7-64. PolAccess Input

		Operand Source		
Name	Size	Direct	Indirect	Description
Policy CBA	20		GPR(19:0)	PolCBA Address
PolColor	2	R		Policy Color
PolPktLen	16	R		Policy Packet Length

Table 7-65. PolAccess Output

		Operand Source		
Name	Size	Direct	Indirect	Description
PolColor	2	R		Returned Policy Color

7.4.8 Counter Coprocessor

The Counter coprocessor provides an interface to the Counter Manager for threads. The Counter coprocessor has an eight-deep queue for holding Counter Access commands issued by any of the four threads running in each DPPU. Except for counter reads, the Counter coprocessor will not stall the CLP on synchronous commands unless the queue is full. This allows for one thread to have multiple counter commands outstanding simultaneously. For example one of the threads may have all the outstanding commands in the queue or each thread may have two each. Normal coprocessor operation would only allow one outstanding command per thread.

7.4.8.1 Counter Coprocessor Address Map

Table 7-66. Counter Coprocessor Address Map

Name	Register Number	Size (bits)	Access	Description
CtrDataLo	x‘00’	32	R/W	Counter Data Low. This register holds the least significant 32 bits of a counter on a read commands. On write or add commands the lower 16 bits serve as the data passed to the Counter Manager. (Only bits 15..0 are write accessible).
CtrDataHi	x‘01’	32	R	Counter Data High. This register holds the most significant 32 bits of a counter on a read commands.
CtrControl	x‘02’	12	R/W	Counter Control. The bits have the following meaning: 11:8 = Counter Number. Defines which counter in the Counter-Block should be updated. 7:0 = Block Definition Index. An index in the CounterDefMem.

7.4.8.2 Counter Coprocessor Commands

The Counter coprocessor provides the following commands:

Command	Opcode	Description
CtrInc	0	Counter Increment. Initiates a Modify and Increment command to the Counter Manager. For more information, see *CtrInc (Counter Increment) Command* on page 264.
CtrAdd	1	Counter Add. Initiates a Modify and Add command to the Counter Manager. The coprocessor passes the Counter Manager a 16-bit value to add to the indicated counter. For more information, see *CtrAdd (Counter Add) Command* on page 265.
CtrRd	4	Counter Read. Initiates a Read and No Clear command to the Counter Manager. The Counter Manager returns the counter value to the Counter coprocessor and leaves the counter unmodified. For more information, see *CtrRd (Counter Read) / CtrRdClr (Counter Read Clear) Command* on page 265.
CtrRdClr	5	Counter Read with Counter Clear. Initiates a Read and Clear command to the Counter Manager. The Counter Manager returns the counter value to the Counter coprocessor and resets the counter. For more information, see *CtrRd (Counter Read) / CtrRdClr (Counter Read Clear) Command* on page 265.
CtrWr15_0	6	Counter Write Bits 15:0 of a Counter. Initiates a Write Command to the Counter Manager. The coprocessor passes a 16-bit value to be loaded into bits 15:0 of the counter. Uses LSB of counter data low register. For more information, see *CtrWr15_0 (Counter Write 15:0) / CtrWr31_16 (Counter Write 31:16) Command* on page 266.
CtrWr31_16	7	Counter Write Bits 31:16 of a Counter. Initiates a Write Command to the Counter Manager. The coprocessor passes a 16-bit value to be loaded into bits 31:16 of the counter. Uses LSB of counter data low register. For more information, see *CtrWr15_0 (Counter Write 15:0) / CtrWr31_16 (Counter Write 31:16) Command* on page 266.

CtrInc (Counter Increment) Command

CtrInc performs an access to the central counter manager to increment a counter. This command does not cause synchronous commands to stall if the Counter coprocessor queue is not full.

Table 7-67. Ctrinc Input

		Operand Source		
Name	Size	Direct	Indirect	Description
BlockIndex	20		GPR(19..0)	Defines a CounterBlock within an array of CounterBlocks
CtrControl	12		R(11..0)	Counter Control. The bits have the following meaning: 11:8 = Counter Number. Defines which counter in the Counter-Block should be updated. 7:0 = Block Definition Index. An index in the CounterDefMem.

CtrAdd (Counter Add) Command

CtrAdd performs an access to the central counter manager to add a 16-bit value to a counter. This command will not cause synchronous commands to stall if the Counter coprocessor queue is not full.

Table 7-68. CtrAdd Input

		Operand Source		
Name	Size	Direct	Indirect	Description
BlockIndex	20		GPR(19..0)	Defines a CounterBlock within an array of CounterBlocks
CtrDataLo	16		R(15..0)	The value to be added to the counter.
CtrControl	12		R(11..0)	Counter Control. The bits have the following meaning: 11:8 = Counter Number. Defines which counter in the Counter-Block should be updated. 7:0 = Block Definition Index. An index in the CounterDefMem.

CtrRd (Counter Read) / CtrRdClr (Counter Read Clear) Command

CtrRd / CtrRdClr performs an access to the central counter manager to read a counter. The CtrRdClr command also clears the counter after the read is performed.

Table 7-69. CtrRd/CtrRdClr Input

		Operand Source		
Name	Size	Direct	Indirect	Description
BlockIndex	20		GPR(19..0)	Defines a CounterBlock within an array of CounterBlocks
CtrControl	12		R(11..0)	Counter Control. The bits have the following meaning: 11:8 = Counter Number. Defines which counter in the Counter-Block should be updated. 7:0 = Block Definition Index. An index in the CounterDefMem.

Table 7-70. CtrRd/CtrRdClr Output

		Operand Source		
Name	Size	Direct	Indirect	Description
CtrDataLo	32		R	For 32-bit counters this register contains the value of the counter once the read is performed. For 64-bit counters, this register contains the least significant 32 bits of the counter once the read is performed.
CtrDataHi	32		R	For 32-bit counters this register is not valid. For 64-bit counters, this register contains the most significant 32 bits of the counter once the read is performed.

CtrWr15_0 (Counter Write 15:0) / CtrWr31_16 (Counter Write 31:16) Command

CtrWr15_0/CtrWr31_16 performs an access to the central counter manager to write a 16-bit value to a counter. The CtrWr15_0 writes the 16-bit data value to bits 15 ..0 of the counter and the CtrWr31_16 writes the value to bits 31 ..16 of the counter. This command does not cause synchronous commands to stall if the Counter coprocessor queue is not full.

Table 7-71. CtrWr15_0/CtrWr31_16 Input

		Operand Source		
Name	Size	Direct	Indirect	Description
BlockIndex	20		GPR(19..0)	Defines a CounterBlock within an array of CounterBlocks
CtrDataLo	16		R(15..0)	The value to be written to the counter
CtrControl	12		R(11..0)	Counter Control. The bits have the following meaning: 11:8 = Counter Number. Defines which counter in the CounterBlock should be updated. 7:0 = Block Definition Index. An index in the CounterDefMem.

7.4.9 Semaphore Coprocessor

The semaphore manager and coprocessor are available in NP4GS3B (R2.0). The Semaphore coprocessor provides an interface for threads to the Semaphore Manager. The Semaphore coprocessor supports one outstanding coprocessor command per thread, and indicates a busy status until the command has been serviced.

7.4.9.1 Semaphore Coprocessor Commands

The Semaphore coprocessor provides the following commands:

Command	Opcode	Description
Semaphore Lock	0	Request to lock a semaphore. Parameters include: thread semaphore number, orderID, semaphore value. This command is complete when the semaphore is locked. The minimum time to complete a lock is five cycles. This represents the amount of time busy signal is asserted: five cycles if the lock is granted immediately, more if it is blocked.
Semaphore Unlock	1	Request to unlock a semaphore. Parameters include: thread semaphore number. This command is complete when the semaphore is unlocked. The time to complete an unlock is three cycles (the amount of time the busy signal is asserted).
Reservation Release	2	Request to remove a semaphore reservation from a queue. Parameters include: orderID. This command is complete when the reservation is released. The time to complete a release is three cycles (the amount of time the busy signal is asserted).

Note: The busy signal will not be asserted if a Lock no-op, Unlock no-op, or Reservation Release no-op is issued.

The following tables show the details of what is included in the commands:

Table 7-72. Semaphore Lock Input

		Operand Source		
Name	Size	Direct	Indirect	Description
SemNr	1	Imm16(0)	Imm12(0)	Selects one of the two semaphores that can be owned by a thread.
OrderID	2	Imm16(3..2)	Imm12(3..2)	00: Use Unordered Semaphore 01: Use Ordered Semaphore ID = 0 10: Use Ordered Semaphore ID = 1 11: no-op
4MSBAddressBits	4	Imm16(7..4)	Imm12(7..4)	These four bits are ORed to the upper 4 bits of address.
Address	32	Imm16(15..8)	GPR(31..0)	The Semaphore Value (in Direct Mode, the 8 Address bits are right-justified, the 4 MSBAddress Bits are ORed with x'0' and left-justified, and the remaining bits are 0s)

Note: There are no restrictions about how OrderID and SemNr are used in conjunction with each other. For example, although perfectly legal, there is no requirement that a lock request wishing to use Ordered Semaphore ID = 1 also request SemNr = 1. It is acceptable to request Ordered Semaphore ID = 1 and SemNr = 0, and vice versa.

Table 7-73. Semaphore Unlock Input

		Operand Source		
Name	Size	Direct	Indirect	Description
SemNr	2	Imm16(1..0)	GPR(1..0)	Selects the semaphores that can be owned by a Thread. 00: no-op 01: Unlock Semaphore SemNr 0 10: Unlock Semaphore SemNr 1 11: Unlock Semaphore SemNr 0 AND 1

Table 7-74. Reservation Release Input

		Operand Source		
Name	Size	Direct	Indirect	Description
OrderID	2	Imm16(3..2)	GPR(1..0)	00: no-op 01: Release Ordered Semaphore ID 0 10: Release Ordered Semaphore ID 1 11: Release Ordered Semaphore ID 0 AND 1

Note: When using the Reservation Release instruction, the thread must wait for completion of this instruction before exiting. The Reservation Release command must be issued synchronously, or it must be issued asynchronously followed by a wait command to the Semaphore coprocessor.

7.4.9.2 Error Conditions

These error conditions generate error interrupts on a per-thread basis:

1. Exit and Locked. If an Exit instruction is executed and the thread still has a locked semaphore, the semaphore manager will receive information from the DPPU indicating that a thread has exited. The semaphore manager unlocks the semaphore and then generates an error. If another thread was pending on the thread that causes the error, the pending thread might hang.

If a thread issues an asynchronous lock request that goes pending and then exits before the request is completed, this error will be reported via the Semaphore Errors Register. This might cause this thread to hang during a subsequent dispatch, or cause another thread requiring the requested semaphore to hang.

2. Lock Same Sem Value. If a thread tries to lock a second semaphore with the same value as the first one it already has locked, the semaphore manager will not lock the semaphore and an error will be reported via the Semaphore Errors Register.
3. Lock Same Sem Number. If a thread tries to lock a semaphore number (0 or 1) that it already has locked (regardless of semaphore value), the semaphore manager will not grant the lock. It will unlock the semaphore that was in that position and will generate an error. If another thread was pending on the thread that causes the error, the pending thread might hang.
4. Queue Not Enabled. If a thread tries to lock an ordered semaphore, but the OrderEnable[ThreadNum] bit is not set, an error is generated. The semaphore manager will grant the lock anyway. The lock request will internally be made to look like an unordered lock request and will be processed as though it were an unordered lock request originally.
5. Label Released and Reservation Unused. When an Enqueue With Label or a Release Label instruction is executed and the thread still has an entry pending on the ordered semaphore queues ID = 0 or ID = 1 which it has not used, an error will be reported via the Semaphore Errors Register.

There is a precedence with regard to multiple errors present in one command (only errors 2, 3, and 4 described above can happen all in one request). The error precedence order for errors 2, 3, and 4 is as follows:

1. Error 3 (Lock Same Sem Number) will be detected and will prevent Errors 2 and 4 from being detected.
2. Error 4 (Queue Not Enabled) and Error 2 (Lock Same Sem Val) will both be detected if Error 3 is not present.

For example, a thread in its initial state might have no OrderID queues enabled and SemNr 0 locked with a Semaphore Value X. If that thread sends in a request for an ordered lock of SemNr 0 and Semaphore Value X, it results in error conditions 2, 3, and 4. However, the Semaphore Manager will detect one of the errors first (Error 3), generate the error interrupt and complete the request before detecting any of the other errors. On the other hand, assuming the same initial state as above, if a thread sends in a request for an ordered lock of SemNr 1 and Semaphore Value X, which results in errors 3 and 4, both errors will be detected and reported.

7.4.9.3 Software Use Models

A few rules should be followed when writing software that will use semaphores in order to prevent software lockups due to improper use of semaphores. These rules apply when the software is attempting to have two semaphores locked at the same time.

1. SemNr 0 and SemNr 1 should always be different “families” of semaphore values. In other words, a semaphore value locked in position SemNr 0 should never be locked in position SemNr 1. One way to accomplish this is to use the four most significant address bits to represent resources that are allowed to be locked in one of the two “families” of semaphore values.
2. SemNr 0 should always be locked first, followed by SemNr 1.
3. Ordered semaphore operations (ordered lock requests or reservation releases) must be completed before the first enqueue and are not permitted after that.

7.5 Interrupts and Timers

The NP4GS3 provides a set of hardware and software interrupts and timers for the management, control, and debug of the processor. When an interrupt event occurs or a timer expires a task is scheduled to be processed by the Embedded Processor Complex. The interrupt or timer task does not preempt threads currently processing other tasks, but is scheduled to be dispatched to the next idle thread that is enabled to process the interrupt or timer. The starting address of the task is determined by the Interrupt or Timer Class and read from *Table 7-78: Port Configuration Memory Content* on page 274.

7.5.1 Interrupts

The interrupt mechanism within the NP4GS3 has several registers: the Interrupt Vector Registers 0-3, Interrupt Mask Register 0-3, Interrupt Target Register 0-3. and the Software Interrupt Registers.

7.5.1.1 Interrupt Vector Registers

The Interrupt Vector Register is a collection of interrupts that will share a common code entry point upon dispatch to a thread in the EPC. A bit representing the individual interrupt within the Interrupt Vector Register is only set on the initial event of the interrupt. Even if the Interrupt Vector Register is cleared, an outstanding interrupt will not set the bit in the register again until it is detected that the interrupt condition is going from an inactive to active state. Picocode can access the Interrupt Vector registers either through the dashboard or through the master copy. The Interrupt Vector Register is cleared when it is read from its Master Copy address. When read from the dashboard, the register is not cleared.

7.5.1.2 Interrupt Mask Registers

The Interrupt Mask Registers have a bit to correspond with each bit in the Interrupt Vector Registers. The Interrupt Mask Registers indicate which interrupts in the Interrupt Vector Registers cause an task to be scheduled for processing by the EPC. The Interrupt Mask Registers have no affect on the setting of the Interrupt Vector Registers.

7.5.1.3 Interrupt Target Registers

The Interrupt Target Register indicates which Thread types in the EPC are enabled to process the interrupt of a given class 0-3.

7.5.1.4 Software Interrupt Registers

The Software Interrupt Registers provide 12 unique interrupts (three in each of the four classes) that can be defined by Software and accessed through CAB addresses. Writing a Software Interrupt Register sets the corresponding bit within the Interrupt Vector Register 0-3 and has the same effect as a hardware-defined interrupt.

7.5.2 Timers

The NP4GS3 has four Timer Interrupt Counters that can be used to generate delayed interrupts to the EPC.

7.5.2.1 Timer Interrupt Counters

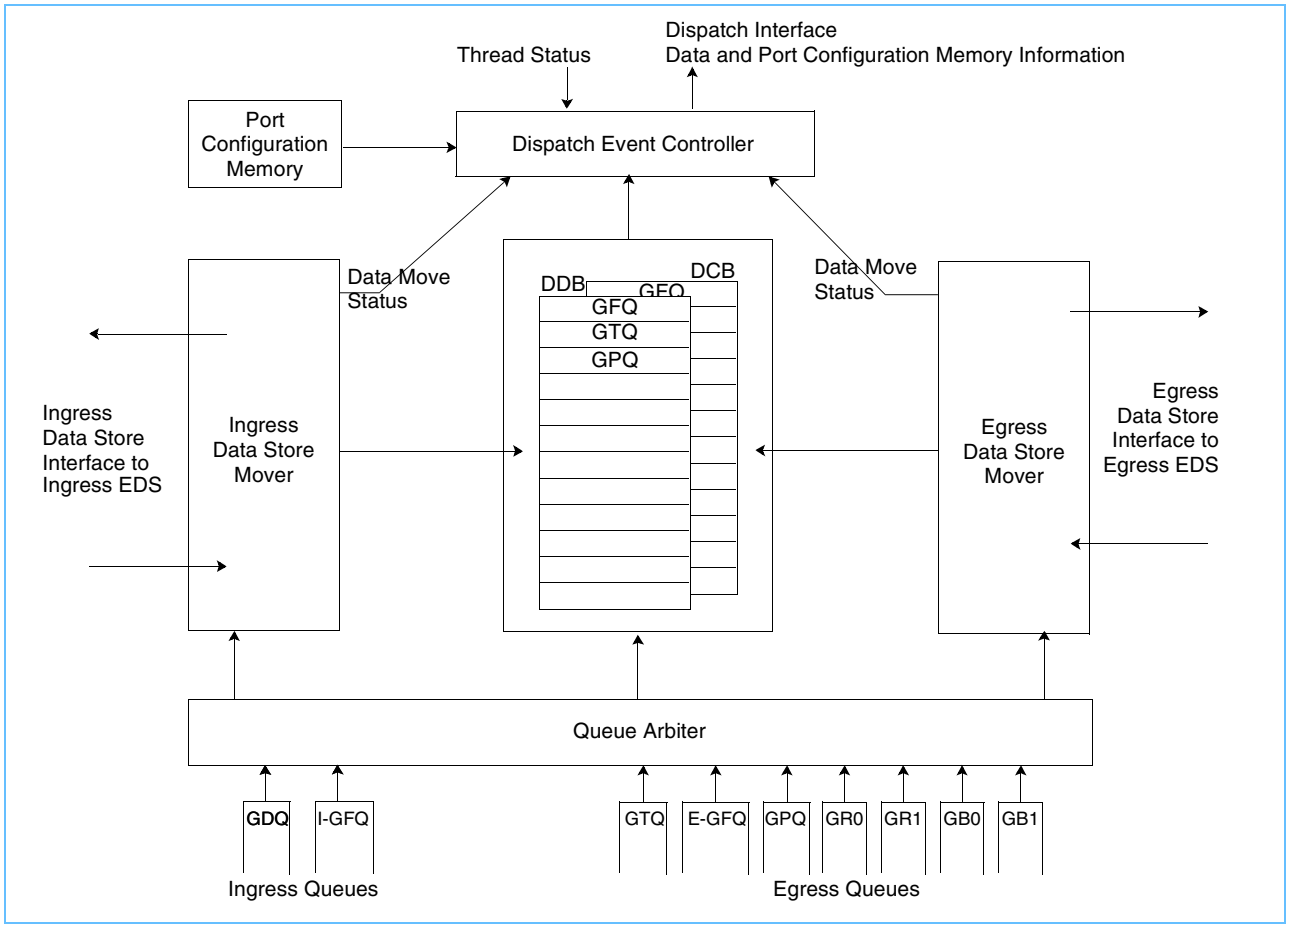
Timer Interrupt Counters 0-2 are 24 bits in length and decrement at 1 ms intervals. Timer Interrupt Counter 3 is 32 bits in length and decrements at 10 μs intervals. The Timer Interrupt Counters are activated by writing a non-zero value to the register. When the Timer decrements to a zero value it will schedule a timer task to be processed by the EPC

7.6 Dispatch Unit

The Dispatch Unit tracks thread usage and fetches initial data of frames prior to assigning a thread to a task. It also handles timers and interrupts by dispatching the work for these to an available thread.

The Dispatch Unit fetches frame data from the Ingress and Egress Data Stores for frame traffic work. The data is placed into the Dispatch Data Buffer (DDB), an array maintained by the Dispatch Unit. There are 12 entries in the array in NP4GS3A (R1.1) and 24 entries in NP4GS3B (R2.0). Each entry holds data for one frame dispatch. Three of the locations are fixed in use. The remaining nine (NP4GS3A (R1.1)) or 12 entries (NP4GS3B (R2.0)) are used for work from the remaining egress frame queues, GR0, GR1, GB0, and GB1, and the ingress GDQ queues.

Figure 7-18. Dispatch Unit



The three fixed locations hold data for frame traffic from the ingress and egress Guided Frame Handler (GFQ) queues, the egress General Table Handler (GTQ) queue, and the request and egress only General PowerPC Handler (GPQ) queues.

The Dispatch Unit selects work from interrupts, timers, and frame queues. There are nine frame queues, four timer interrupts, and four hardware interrupts. If a queue is not empty and there is room in the DDB for data for a queue type, then the Dispatch Unit's Queue Arbiter considers the queue a candidate for selection via a priority, ingress/egress driven, round-robin process. See *Table 7-75: Priority Assignments for the Dispatch Unit Queue Arbiter* on page 271 for the queues and priority weights. The lower the priority number, the higher the priority selection weight.

Selection toggles between the ingress groups and egress groups. If there are no candidates in one group, then the other group may be selected during consecutive opportunities. In order to keep either the ingress or the egress work from taking up the entire DDB and thus starving the opposite group, a threshold is maintained for both. These thresholds are compared against the nine entries (NP4GS3A (R1.1)) or 12 entries (NP4GS3B (R2.0)) in the DDB from the ingress and egress work groups. If a threshold is exceeded, then no further work for that group is allowed into the DDB. Simulation has shown that a value of 6 (NP4GS3A (R1.1)) or 16 (NP4GS3B (R2.0)) for each group's threshold maximizes the dispatch unit throughput and does not allow either group to starve from lack of processor resources.

Table 7-75. Priority Assignments for the Dispatch Unit Queue Arbiter

Queue	Priority
Ingress group	
I-GFQ	1
GDQ	2
Egress group	
E-GFQ	1
GTQ	2
GPQ	3
GR0	4
GR1	4
GB0	5
GB1	5

Once a frame has been selected by the queue arbiter, that frame's data is fetched into the DDB. Any relevant information about the frame's queue entry is fetched into the Dispatch Control Block (DCB). The amount of data fetched is dependent on the queue's port configuration memory contents. The port configuration memory is an array used by the dispatch unit that contains entries for all ingress ports, interrupts, and egress work queues.

The Dispatch Event Controller (DEC) schedules the dispatch of work to a thread. It monitors the status of all 32 threads in the EPC, the status of data movement into the DDB, and the status of the four hardware interrupts and four timers. Work from the GFQ, GTQ, and GPQ may only be processed by the GFH, GTH, and GPH-Req threads respectively. Threads that are allowed to handle interrupts and timers are configurable; they can be restricted to a single thread type, or can be processed by any thread. The DEC assures that there is a match between an available thread and the type of work to be performed. The DEC load balances threads on the available DPPUs and CLPs, keeping the maximum number of threads running in parallel in the EPC.

When a thread is available for work, and there is a match between the thread and ready work unit, and all the data has been moved for the work unit, then the work unit is dispatched to the thread for processing. The DEC provides the data fetched from the DDB and the contents of the Port Configuration Memory corresponding to the entry. When multiple units of work are ready to go that match available threads, the DEC toggles between ingress and egress work units.

There is no data movement for timers and interrupts. Only the contents of the Port Configuration Memory entry are passed to the thread.

7.6.1 Port Configuration Memory

Table 7-78: Port Configuration Memory Content on page 274 provides control, default, and software defined information on each dispatch and is passed to the thread to be stored in the Configuration Quadword array in the Data Store coprocessor.

7.6.1.1 Port Configuration Memory Index Definition

The Port Configuration Memory Index consists of 64 entries that are indexed based upon multiple parameters including Ingress port, Egress queues, timers, and interrupts as defined in *Table 7-76*.

Table 7-76. Port Configuration Memory Index

Port Configuration Memory Index	Definition
0 .. 39	Ingress SP (from GDQ)
40	Ingress Wrap Frame (I-GDQ)
41	Reserved
42	I-GFQ
43	Ingress Wrap Guided
44	Reserved
45	GPQ
46	Egress GFQ
47	GTQ
48	Egress frame in either DS0 or DS1
49	Egress frame in DS0 and DS1
50	Reserved
51	Reserved
52	Reserved
53	Reserved
54	Egress Abort of frame in either DS0 or DS1
55	Egress Abort of frame in DS0 and DS1
56	Interrupt 0
57	Interrupt 1
58	Interrupt 2
59	Interrupt 3
60	Timer 0
61	Timer 1
62	Timer 2
63	Timer 3

Table 7-77. Relationship Between SP Field, Queue, and Port Configuration Memory Index

SP field in FCB1	Queue	Port Configuration Memory Index
0 .. 39 (denotes physical port)	GDQ	0 .. 39
0 .. 39 (denotes physical port)	I-GFQ	42
40 (denotes wrap port)	GDQ	40
40 (denotes wrap port)	I-GFQ	43

7.6.2 Port Configuration Memory Contents Definition

Bits 127.. 24 are software defined and are for use by the picocode. The remaining bits are used by the hardware, as defined in *Table 7-78*.

Table 7-78. Port Configuration Memory Content

Field Name	Bits	Description
	127 .. 24	For Software use
POS_AC	23	0 AC not Present 1 AC Present
Ethernet/PPP	22	0 PPP port 1 Ethernet port
CodeEntryPoint	21.. 6	The default code entry point. Can be overwritten by the hardware classifier (if enabled).
CULabGenEnabled	5	0 No label is generated 1 The Hardware Classifier generates a label that is used by the Completion Unit to maintain frame sequence This field must be set to 0 for Port Configuration Memory entries 54, 55 (representing aborted frames on the Egress), 56-59 (interrupts), and 60-63 (timers).
HardwareAssistEnabled	4	0 Hardware Classifier is disabled 1 Hardware Classifier is enabled and the classifier may overwrite the CodeEntryPoint
Reserved	3 .. 2	Reserved. Set to ‘00’.
NumberOfQuadWords	1.. 0	Defines the number of quadwords that the Dispatch Unit will read from the frame and store in the DataPool. A value of ‘00’ represents four quadwords. For Port Configuration Memory entries 56-63 (interrupts and timers), this field is ignored and the Dispatch Unit will not write any quadword into the DataPool.

7.7 Hardware Classifier

The Hardware Classifier provides hardware assisted parsing of the ingress and egress frame data that is dispatched to a thread. The results are used to precondition the state of a thread by initializing the thread's General Purpose and Coprocessor Scalar Registers along with the registers' resources and a starting instruction address for the CLP. Parsing results indicate the type of Layer 2 encapsulation, as well as some information about the Layer 3 frame. Recognizable Layer 2 encapsulations include PPP, 802.3, DIX V2, LLC, SNAP header, and VLAN tagging. Reported Layer 3 information includes IP and IPX network protocols, five programmable network protocols, the detection of option fields, and IP transport protocols (UDP and TCP). If enabled, the Hardware Classifier also generates labels that are passed to the Completion Unit with a thread identifier. The CU uses them to maintain frame order within a flow.

7.7.1 Ingress Classification

Ingress classification, the parsing of frame data which originated in the Ingress EDS and is now being passed from the Dispatch Unit to the DPPU, can be applied to Ethernet/802.3 frames with the following Layer 2 encapsulation: DIX V2, 802.3 LLC, SNAP header, and VLAN Tagging. Classification can also be done on POS frames using the Point-to-Point Protocol with or without the AC Field Present (POS_AC) field.

7.7.1.1 Ingress Classification Input

The Hardware Classifier needs the following information to classify an ingress frame:

- Port Configuration Memory Table Entry (*Table 7-78* on page 274). The Hardware Classifier uses the following fields:
  - CodeEntryPoint - the default starting instruction address.
  - HardwareAssistEnabled
  - CULabGenEnabled
  - Ethernet/PPP
  - POS AC
- Frame Data. Four quadwords must be dispatched (per frame) for ingress classification.
- Protocol Identifiers: The Hardware Classifier compares the values in the Protocol Identifier registers with the values of the fields in the frame that correspond to those identifiers to determine if one of the configured protocols is encapsulated in the frame. The Hardware Classifier supports seven Ethernet Protocols (five of which are configurable) and eight Point-to-Point Protocols (five of which are configurable). Two registers need to be configured for each Ethernet Protocol, the Ethernet Type value and an 802.2 Service Access Point value. The Protocol Identifiers are configured from the CAB.

Table 7-79. Protocol Identifiers

CAB Address	Access	Bits	Description
x‘2500 0000’	R/W	16	Ethernet Type for Protocol 0
x‘2500 0010’	R/W	16	Ethernet Type for Protocol 1
x‘2500 0020’	R/W	16	Ethernet Type for Protocol 2
x‘2500 0030’	R/W	16	Ethernet Type for Protocol 3
x‘2500 0040’	R/W	16	Ethernet Type for Protocol 4
x‘2500 0050’	R	16	Ethernet Type for IPX (x‘8137’)
x‘2500 0060’	R	16	Ethernet Type for IP (x‘0800’)
x‘2500 0070’		16	Reserved
x‘2500 0080’	R/W	16	Point to Point Type for Protocol 0
x‘2500 0090’	R/W	16	Point to Point Type for Protocol 1
x‘2500 00A0’	R/W	16	Point to Point Type for Protocol 2
x‘2500 00B0’	R/W	16	Point to Point Type for Protocol 3
x‘2500 00C0’	R/W	16	Point to Point Type for Protocol 4
x‘2500 00D0’	R	16	Point to Point Type for IPX (x002B’)
x‘2500 00E0’	R	16	Point to Point Type for IP (x0021’)
x‘2500 00F0’	R	16	Point to Point Control Type Frame (MSBs of type field is ‘1’)
x‘2500 0100’	R/W	8	Service Access Point for Protocol 0
x‘2500 0110’	R/W	8	Service Access Point Type for Protocol 1
x‘2500 0120’	R/W	8	Service Access Point Type for Protocol 2
x‘2500 0130’	R/W	8	Service Access Point Type for Protocol 3
x‘2500 0140’	R/W	8	Service Access Point Type for Protocol 4
x‘2500 0150’	R	8	Service Access Point Type for IPX (x‘E0’)
x‘2500 0160’	R	8	Service Access Point Type for IP (x‘06’)
x‘2500 0170’		8	Reserved

7.7.1.2 Ingress Classification Output

The outputs of the ingress hardware classification are:

- The Starting Instruction Address that is stored in the HCCIA table. This address is only used when the hardware classification is enabled. When the hardware classification is disabled, or if a protocol match is not found, the Code Entry Point from the Port Configuration Memory table (*Table 7-78: Port Configuration Memory Content* on page 274) is used as the Starting Instruction Address and is passed to the thread. If a protocol match does occur, the starting instruction address is retrieved from the last 24 entries of the HCCIA table. HCCIA values are configured from the CAB. The address into HCCIA are provided in *Table 7-80: HCCIA Table* on page 277.

Table 7-80. HCCIA Table

HCCIA CAB Address	Bits	Classification
x'2500 0400' x'2500 05F0'	16	Egress Locations (see section *7.7.2.1 Egress Classification Input* on page 279)
x'2500 0600'	16	Ethernet Protocol 0 classification with no 802.1Q VLAN
x'2500 0610'	16	Ethernet Protocol 1 classification with no 802.1Q VLAN
x'2500 0620'	16	Ethernet Protocol 2 classification with no 802.1Q VLAN
x'2500 0630'	16	Ethernet Protocol 3 classification with no 802.1Q VLAN
x'2500 0640'	16	Ethernet Protocol 4 classification with no 802.1Q VLAN
x'2500 0650'	16	Ethernet IPX classification with no 802.1Q VLAN
x'2500 0660'	16	Ethernet IP classification with no 802.1Q VLAN
x'2500 0670'	16	Ingress Aborted Frame at time of dispatch
x'2500 0680'	16	Ethernet Protocol 0 classification with 802.1Q VLAN
x'2500 0690'	16	Ethernet Protocol 1 classification with 802.1Q VLAN
x'2500 06A0'	16	Ethernet Protocol 2 classification with 802.1Q VLAN
x'2500 06B0'	16	Ethernet Protocol 3 classification with 802.1Q VLAN
x'2500 06C0'	16	Ethernet Protocol 4 classification with 802.1Q VLAN
x'2500 06D0'	16	Ethernet IPX classification with 802.1Q VLAN
x'2500 06E0'	16	Ethernet IP classification with 802.1Q VLAN
x'2500 06F0'	16	Ethernet VLAN frame with an ERIF
x'2500 0700'	16	Point to Point Protocol 0 classification
x'2500 0710'	16	Point to Point Protocol 1 classification
x'2500 0720'	16	Point to Point Protocol 2 classification
x'2500 0730'	16	Point to Point Protocol 3 classification
x'2500 0740'	16	Point to Point Protocol 4 classification
x'2500 0750'	16	Point to Point IPX classification
x'2500 0760'	16	Point to Point IP classification
x'2500 0770'	16	Point to Point Control Frame

Table 7-81. Protocol Identifiers for Frame Encapsulation Types

Frame Encapsulation Type	Data Store Coprocessor Register Setting
SNAP	Ethernet Type
DIX V2	Ethernet Type
SAP	DSAP/SSAP
Point to Point Protocol	Point to Point Type

- Ingress Protocol Type Register

  Contains the output of the Ingress Hardware Classifier. This Data Store coprocessor register is loaded with the protocol identifier that identifies the frame for the given encapsulation type.

  The fields in the frame data that correspond to Data Store coprocessor Register Settings (see *Table 7-81*) are passed to the Ingress Protocol Type register. If a VLAN tagged frame with an E-RIF field is present within the frame, or if the Hardware Classifier is disabled, this field is invalid.

- DLL termination offset

  If the Hardware Classifier is enabled, the DLL termination offset is loaded into GPR R0. The DLL termination offset is defined as the number of bytes, starting at the beginning of the frame, to the position one byte beyond the end of the data link layer. This value is based upon the encapsulation type. Typically, this is the same as the start of the Layer 3 protocol header, an exception would be for MPLS.

- Classification Flags:

  If the Hardware Classifier is enabled, classification flags will be loaded into the thread's GPR R1.

Table 7-82. General Purpose Register Bit Definitions for Ingress Classification Flags

Bit	Definition
Bit 15	Protocol 7 detected
Bit 14	Protocol 6 detected
Bit 13	Protocol 5 detected
Bit 12	Protocol 4 detected
Bit 11	Protocol 3 detected
Bit 10	Protocol 2 detected
Bit 9	Protocol 1 detected
Bit 8	Protocol 0 detected
Bit 7	'0'
Bit 6	Indicates IP Options field present
Bit 5	DIX encapsulation
Bit 4	Indicates SAP encapsulation
Bit 3	Indicates SNAP encapsulation
Bit 2	Indicates 802.1q VLAN frame
Bit 1	Indicates the 802.1q VLAN ID was non-zero
Bit 0	Indicates an ERIF present

- Flow Control Information

  The Hardware Classifier initializes the FCBPage's Flow Control Information (FCInfo) field. The field's value is based on IP frame information that includes the frame color indicated by bits 4:3 of the IP header's TOS field and the TCP header's SYN bit. The Hardware Classifier never sets FCInfo field to '1111' but once the field is in the FCBPage it can be written by picocode to be a '1111'.

Table 7-83. Flow Control Information Values

FCInfo	Definition
0000	TCP - Green
0001	TCP - Yellow
0010	TCP - Red
0011	Non-IP
0100	UDP - Green
0101	UDP - Yellow
0110	UDP - Red
0111	Reserved
1000	TCPSYN- Green
1001	TCPSYN - Yellow
1010	TCPSYN - Red
1011	Reserved
1100	Other IP - Green
1101	Other IP - Yellow
1110	Other IP - Red
1111	Disable Flow Control

7.7.2 Egress Classification

Egress classification, the parsing of frame that originated in the Egress EDS and is being transferred from the Dispatcher to the DPPU is limited to choosing a starting instruction address and generating a label to pass to the Completion Unit.

7.7.2.1 Egress Classification Input

For egress frames, the Hardware Classifier needs the following information to classify the frame:

- Port Configuration Memory Table Entry (*Table 7-78* on page 274). The Hardware Classifier uses the following fields:
  - CodeEntryPoint- the default starting instruction address
  - HardwareAssistEnabled
  - CULabGenEnabled
- Frame Data. One quadword must be dispatched (per frame) for egress classification.

7.7.2.2 Egress Classification Output

The outputs of the Egress hardware classification are:

- Starting Instruction Address.

  The starting instruction address stored in the HCCIA memory is only used when the hardware classification is enabled. When the hardware classification is disabled, the Code Entry Point from the Port Configuration Memory table (*Table 7-78: Port Configuration Memory Content* on page 274) is used as the Starting Instruction Address and is passed to the thread. The address into HCCIA is given by the UC field and by the FHF field in the frame header:

Table 7-84. HCCIA Index Definition

1	4
UC	FHF

- Frame Data Offset

  GPR R0 is always (i.e. also when the Hardware Classification is disabled) set according to *Table 7-10: Egress Frames DataPool Quadword Addresses* on page 228

- Classification Flags (NP4GS3B (R2.0)):

  If the Hardware Classifier is enabled, classification flags will be loaded into the thread's GPR R1.

Table 7-85. General Purpose Register 1 Bit Definitions for Egress Classification Flags

Bit	Definition
Bit 15:1	Reserved
Bit 0	A link pointer error was found during Dispatch Unit access of the Egress data store. Recommended action is to discard the frame.

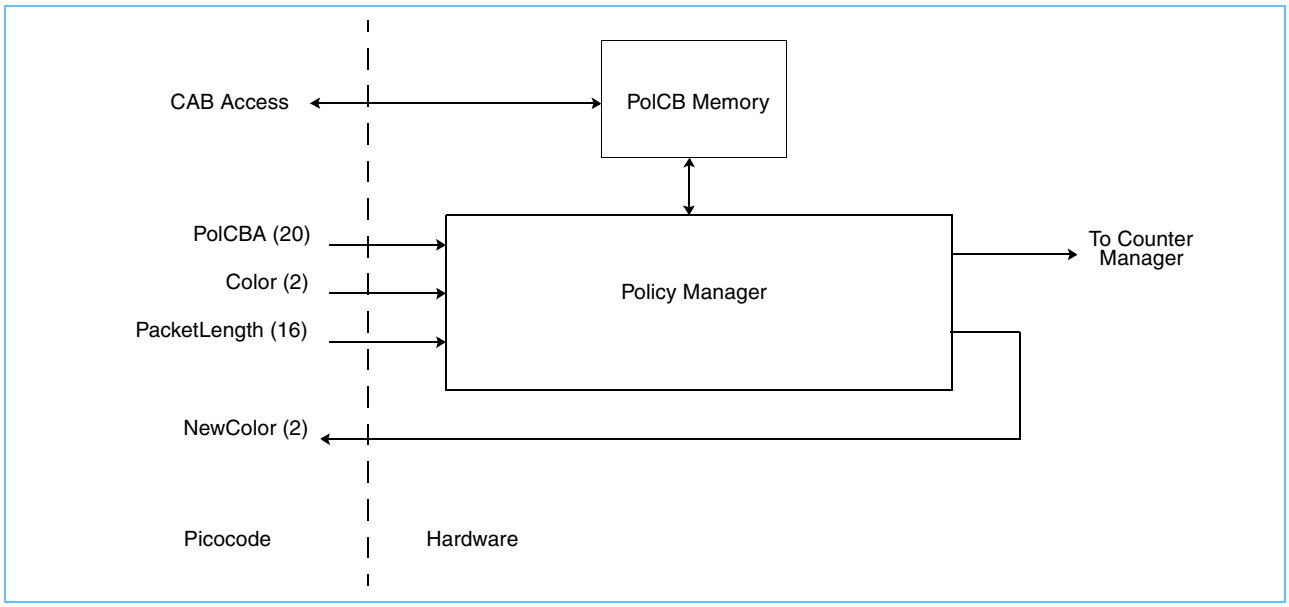
7.8 Policy Manager

The Policy Manager is a hardware assist of the Embedded Processor Complex that performs policy management on up to 1 K ingress flows. It supports four management algorithms. One algorithm pair is "Single Rate Three Color Marker," operated in color-blind or color aware mode. The other is "Two Rate Three Color Marker," operated again in color-blind or color-aware mode. The algorithms are specified in IETF RFCs 2697 and 2698. The algorithms are specified in IETF RFCs 2697 and 2698 (available at http://www.ietf.org).

The Policy Manager maintains up to 1024 leaky bucket meters with selectable parameters and algorithms. The picocode sends the Policy Manager a Policy Manager Control Block Address (PolCBA), a Color, and a Packet Length for each incoming packet. According to the Policy Management Control Block (PolCB), two token counters stored in internal memory are regularly incremented (subject to an upper limit) by a rate specified in the PolCB and, when a packet arrives, are decremented by one of four possible algorithms (depending upon the incoming Packet Length). After both actions are complete, the token counters generally have new values and a new color is returned to the picocode.

In addition there are three 10-bit wide packet counters in the PolCB (RedCnt, YellowCnt, and GreenCnt) that use the output packet colors to count the number of bytes (with a resolution of 64 bytes) of each color. When these counters overflow, the Policy Manager invokes the Counter Manager with an increment instruction and counters maintained by the Counter Manager are used for the overflow count. Counter Definition 0 is reserved for the Policy Manager, and must be configured for these overflow counts.

Figure 7-19. Split between Picocode and Hardware for the Policy Manager



The PolCB must be configured before use. Configuration is accomplished via the CAB. The contents of the PolCB are illustrated in *Table 7-86: PolCB Field Definitions* on page 282.

Classification of a frame by the picocode must result in a PolCBA. The Hardware Classifier provides the color of the frame in the FCBPage. The frame length used must be parsed from the IP packet header by the picocode.

The Policy Manager receives the following inputs from the picocode:

- PolCBA (20 bits)

- Color (2 bits), the color of the incoming packet. These are re-encoded as received in the DS Byte as 00 = green, 01 = yellow, 10 = red. Note that the encoding used does not conform to the RFC 2597.
- Packet Length (in bytes, 16 bits)

The Policy Manager reads the PolCB from the memory, executes the algorithm configured by the type field in the PolCB, writes the updated PolCB back to the memory and returns the new color to the picocode. The Policy Manager can perform these operations once every 15 core clock cycles. Picocode might use this information as follows:

- Perform no special action
- Discard the packet
- Change the DS Byte (i.e., (re-)mark the frame)

Table 7-86. PolCB Field Definitions (Page 1 of 2)

Field	Size	Description
Type	4	Algorithm type. This field must be initialized by picocode. 0000 Color blind single rate three color marker 0001 Color aware single rate three color marker 0010 Color blind two rate three color marker 0011 Color aware two rate three color marker 0100-1111 Reserved
PA_Time	32	Previous arrival time in ticks. This field must be initialized to 0 by the picocode. PA_Time is compared to a running 32-bit counter which is incremented every 165/150 ns. Selection of the accuracy of the counter tick is controlled by the setting of the DRAM Parameter Register bit 22 (11/$\overline{10}$). When set to 1 the tick rate is 165 ns when set to 0 the tick rate is 150 ns.
C_Token	26	Token Counter for Committed rate accounting in bytes. This field must be initialized by picocode to contain the same value as C_BurstSize. (Format is 17.9)
EP_Token	26	Token Counter for Excess or Peak rate accounting in bytes. This field must be initialized by picocode to contain the same value as EP_BurstSize. (Format is 17.9)
CIR	12	Committed Information Rate in bytes/tick used for two rate algorithms. CIR uses an exponential notation X * 8^{Y-3} where 11:3 X 2:0 Y; valid values of Y are '000' through '011' A tick for the policy manager is defined to be either 165 or 150 ns. Selection of the value for a tick is controlled by the setting of the DRAM Parameter Register bit 22 (11/$\overline{10}$). When set to 1 the tick is 165 ns, when set to 0 the tick is 150 ns. This field must be initialized by picocode to meet the service level agreement. The PIR must be equal to or greater than the CIR. CIR can be defined in the range of 100 Kbps through 3 Gbps.
PIR	12	Peak Information Rate in bytes/tick used for two rate algorithms. PIR uses an exponential notation X * 8^{Y-3} where 11:3 X 2:0 Y; valid values of Y are '000' through '011' A tick for the policy manager is defined to be either 165 or 150 ns. Selection of the value for a tick is controlled by the setting of the DRAM Parameter Register bit 22 (11/$\overline{10}$). When set to 1 the tick is 165 ns, when set to 0 the tick is 150 ns. This field must be initialized by picocode to meet the service level agreement. The PIR must be equal to or greater than the CIR. PIR can be defined in the range of 100 Kbps through 3 Gbps.

Table 7-86. PolCB Field Definitions (Page 2 of 2)

Field	Size	Description
C_Burstsize	17	Committed burst size in bytes. This field must be initialized by picocode to meet the service level agreement. For the single rate algorithms, either the C_BurstSize or the EP_BurstSize must be larger than 0. It is recommended that when the value of C_BurstSize or the EP_BurstSize is larger than 0, it is larger than or equal to the size of the MTU for that stream. For the two rate algorithms, C_BurstSize must be greater than 0. It is recommended that it is larger than or equal to the size of the MTU for that stream.
EP_Burstsize	17	Excess or Peak Burst Size in bytes. Definition depends on algorithm selected. This field must be initialized by picocode to meet the service level agreement. For the single rate algorithms, either the C_BurstSize or the EP_BurstSize must be larger than 0. It is recommended that when the value of C_BurstSize or the EP_BurstSize is larger than 0, it is larger than or equal to the size of the MTU for that stream. For the two rate algorithms, EP_BurstSize must be greater than 0. It is recommended that it is larger than or equal to the size of the MTU for that stream.
GreenCnt	10	Number of bytes (with 64-byte resolution) in packets flagged as “green” by the Policy Manager. When this counter overflows, the Policy Manager uses the Counter Manager interface to increment an extended range counter. This field must be initialized to 0 by picocode. The counter control block for the Policy Manager must be configured at Counter Definition Table entry 0. The Green Count is counter number 0.
YellowCnt	10	Number of bytes (with 64-byte resolution) in packets flagged as “yellow” by the Policy Manager. When this counter overflows, the Policy Manager uses the Counter Manager interface to increment an extended range counter. This field must be initialized to 0 by picocode. The counter control block for the Policy Manager must be configured at Counter Definition Table entry 0. The Yellow Count is counter number 1.
RedCnt	10	Number of bytes (with 64-byte resolution) in packets flagged as “red” by the Policy Manager. When this counter overflows, the Policy Manager uses the Counter Manager interface to increment an extended range counter. This field must be initialized to 0 by picocode. The counter control block for the Policy Manager must be configured at Counter Definition Table entry 0. The Red Count is counter number 2.

7.9 Counter Manager

The Counter Manager is a hardware assist engine used by the EPC to control various counts used by the picocode for statistics, flow control, and policy management. The Counter Manager is responsible for counter updates, reads, clears, and writes, and it allows the picocode to access these functions using single instructions. The Counter Manager arbitrates between all requestors and acknowledges when the requested operation is completed. The Counter Manager works in concert with the Counter coprocessor logic to allow the picocode access to the various counters.

The Counter Manager supports the following:

- 64-bit Counters
- 32-bit Counters
- 24/40-bit Counters
- Read, Read/Clear, Write, Increment, and Add functions
- A maximum of 1 K 64-bit, 2 K 32-bit, or some mix of the two not to exceed a total size of 64 Kb, of fast internal counters
- Up to 4 M 64-bit or 32-bit external counters. Two 32-bit counters are packed into a 64-bit DRAM line. Selection of the counter is accomplished by the low-order address bit.
- Counter Definition Table for defining counter groups and storage locations
- Interfaces to all eight DPPUs, the Policy Manager, Ingress and Egress Flow Control
- Five Independent Counter Storage locations

Figure 7-20. Counter Manager Block Diagram

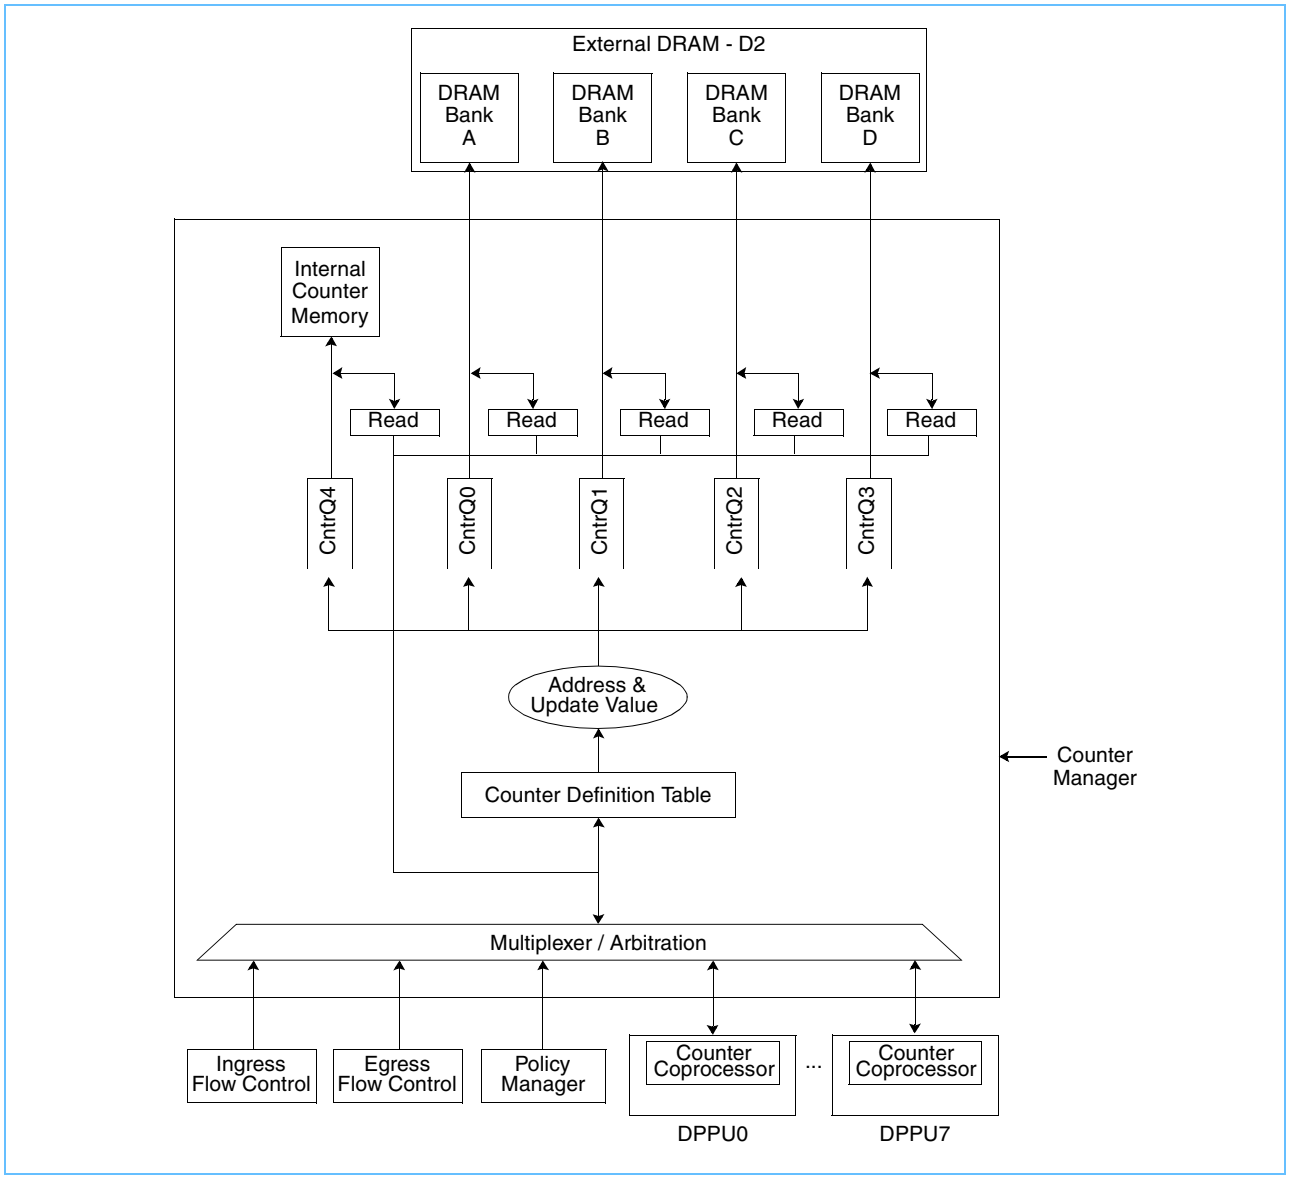


Table 7-87. Counter Manager Components

Component Name	Description
Counter Definition Table	Contains definitions for each counter block (256 entries). A counter block is made up of the counter's memory storage location (Bank A, Bank B, Bank C, Bank D, or Internal), the base address within that memory, the number of counters within the set, and the counter size.
Multiplexing and Arbitration	Multiplexing and arbitration logic selects the next counter action from all requestors according to priority. Flow Control has the highest priority, Policy Manager the next, and the set of DPPUs the lowest priority. Multiplexing and arbitration logic uses two work conserving round-robins: one between the two Flow Control requestors and one for the set of DPPUs. This logic returns the read data to the appropriate requestor during counter reads.
Address and Update Value	Address and Update Value logic uses information gathered from the Counter Definition Table and the parameters passed from the requestor to create the final counter address and update value.
CntrQ0 - CntrQ4	Five Counter Queues used to temporarily hold the counter request and allow the Counter Manager to access all five memory locations independently. The request is placed into the appropriate queue based on the memory storage location information found in the Counter Definition Table.
Read	Read logic gathers the read data from the appropriate memory location and returns it to the requestor.
Internal Counter Memory	Internal Counter Memory holds the "fast" internal counters and can be configured to hold 64-bit, 24/40-bit, or 32-bit counters. The Internal Counter Memory size is 1024 locations x 64 bits.

Table 7-88. Counter Types

Type Name	Description
64-bit Counter	Counter that holds up to a 64-bit value.
24/40-bit Counter	Special 64-bit counter that has a standard 40-bit portion and a special 24-bit increment portion. The 40-bit portion is acted upon by the command passed and the 24-bit portion is incremented. This counter allows "byte count" and "frame count" counters to be in one location; the 40-bit portion is the byte count, and the 24-bit portion is the frame count.
32-bit Counter	Counter that holds up to a 32-bit value.

Table 7-89. Counter Actions

Action Name	Description
Read	Read Counter and return value (either 64 or 32 bits) to the EPC.
Read/Clear	Read Counter and return value (either 64 or 32 bits) to the EPC. Hardware then writes counter to zero.
Write	Write 16 bits to the counter (either bits 31:16 or 15:0) and zero all other bits.
Increment	Add one to the counter value and store updated value in memory.
Add	Add 16 bits to the counter value and store updated value in memory.

7.9.1 Counter Manager Usage

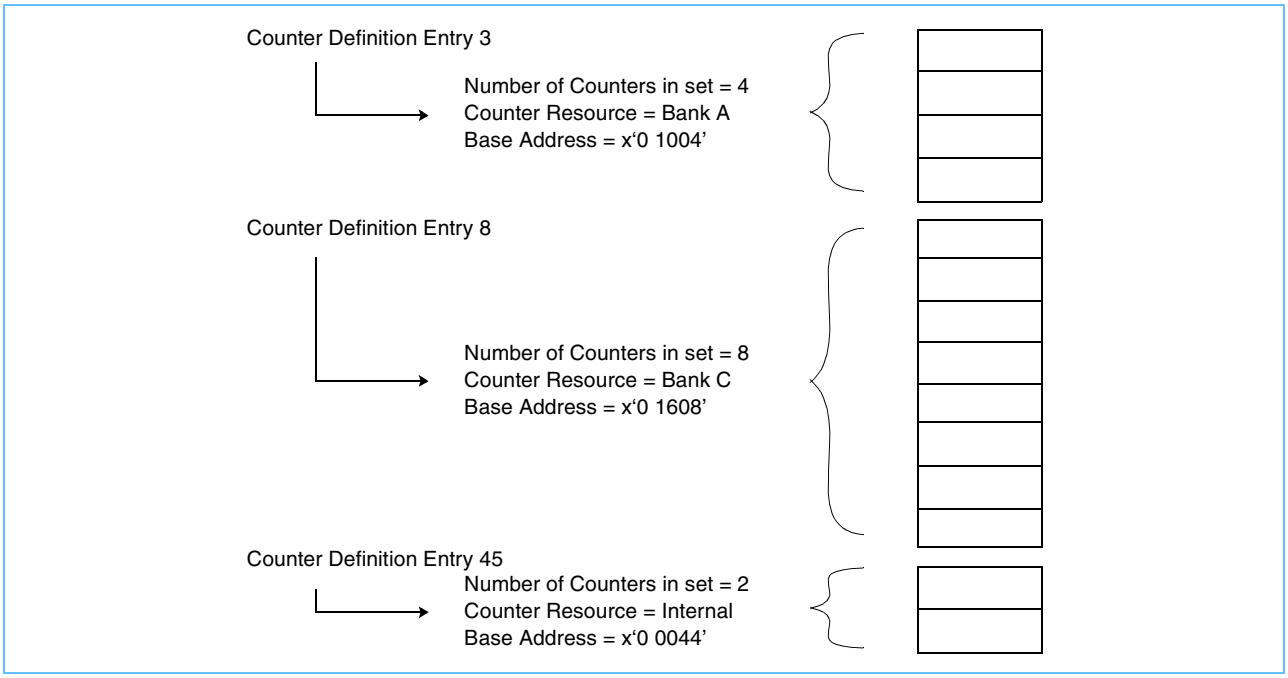
The Counter Manager manages various counters for the EPC. The EPC, Policy Manager, and the Ingress and Egress Flow Control have the ability to update these counters. The picocode accesses these counters for statistics, flow control actions, and policy decisions. Before a counter can be used, its counter definition entry must be configured. This entry defines where the counter is stored, how many counters are associated with this set, and the counter's size. The Counter Manager supports 256 different counter definition entries. The counter definition entry is written to the Counter Definition Table using the CAB. The entry format in shown in *Table 7-90*.

Table 7-90. Counter Definition Entry Format

Field	Bits	Definition
Reserved	31:30	Not used.
24/40	29	Flag to indicate 24/40 counter (1 = 24/40). If set, 64 / $\overline{32}$ must also be set to 1.
64 / $\overline{32}$	28	Flag to indicate a 64-bit counter (1 = 64) or a 32-bit counter (0 = 32).
Number of Counters	27:23	Number of counters within this counter set. Legal values: 1, 2, 4, 8, or 16
Counter Resource Location	22:20	Storage used for the counter block. 000 Bank A 001 Bank B 010 Bank C 011 Bank D 100 Internal Memory
Base Address	19:0	Base Address within the memory where the counter block starts. Counter addresses are based on a 64-bit word, however, all address bits are not used for all counter resource locations and when a 32-bit counter is indicated (bit 28 is set to 0), address bit 0 indicates the counter location within the 64-bit word (0 = bits 31:0, 1 = bits 63:32). The following illustrates the use of the base address bits. 32-bit counter / Counter Resource Location / 64-bit word address Yes '000' - '011' 19:1 Yes '100' 11:1 No '000' - '011' 19:0 No '100' 10:0

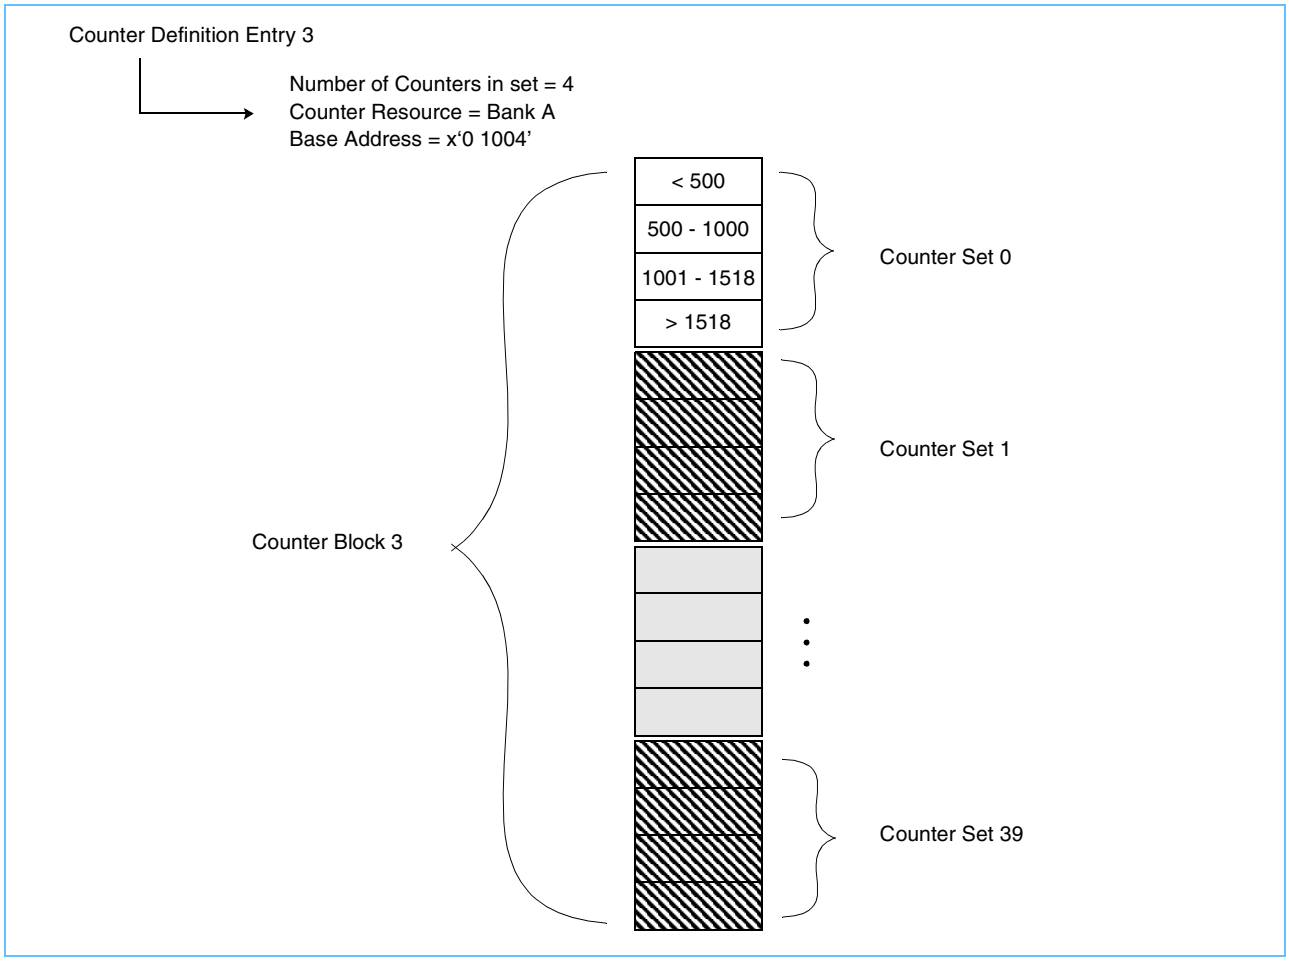
The Counter Definition Entry describes a set of counters that have similar characteristics and are referenced from the picocode as a single group. The following figure shows several counter definition examples.

Figure 7-21. Counter Definition Entry



Each Counter Definition Entry can be used for a block of counter sets. The definition describes one counter set and the picocode can reference several consecutive counter sets using the same definition. For example, a counter set is defined as four counters: one for frames less than 500 bytes, one for frames between 500 and 1000 bytes, one for frames between 1001 and 1518 bytes, and the last one for frames greater than 1518. One Counter Definition Entry describes the counters, and picocode can use the definition to reference 40 similar sets of these counters, that is, one for each source port. Counter Set 0 is located at the Base Address defined by the entry, Counter Set 1 is located at the next available address, and so on. *Figure 7-21* shows an example of counter blocks and sets.

Figure 7-22. Counter Blocks and Sets



To reference the correct counter, the requestor must pass the Counter Manager several parameters. These parameters are described in *Table 7-91*.

Table 7-91. Counter Manager Passed Parameters

Parameter	Bits	Definition
Counter Definition Table Index	8	Counter Definition Entry to use for this action
Counter Set Index	20	Set of counters to reference
Counter Number	4	Counter within the set to reference
Action	3	Action to perform on the counter Modify 000 Increment by 1 001 Add 16 bits to counter Read 100 Standard read 101 Read then Clear value Write 110 Write bits 15:0 of counter 111 Write bits 31:16 of counter All other code points are reserved.
Add/Write Value	16	Value to add to counter when Modify/Add selected Value to write to counter when Write selected
Flow Control Action (Counter Definition Table Index Offset)	2	Only used by Flow Control Interfaces 00 Standard Enqueue 01 Discard (resulting from the Transmit Probability table) 10 Tail Drop Discard 11 Reserved

The Counter Manager builds the actual counter address using the following algorithm:

Address = Base Address + (Counter Set Index * Number of Counters) + Counter Number

This address is used to access the counter within the appropriate memory (Bank A, Bank B, Bank C, Bank D, or Internal). When a 32-bit counter is accessed, the low order bit of the address selects which 32 bits of the 64-bit memory word are being used: 0 = bits 31:0, 1 = bits 63:32.

The location of the counter and its size determine how many address bits are used by the Counter Manager as seen in *Table 7-92*.

Table 7-92. Counter Manager use of Address Bits

Memory Location	Counter Size	Number of Counters stored at Single Memory Address	Number of Address bits used	Total Counters Possible
Internal	32	2	11 (10:0) where bit 0 selects upper or lower 32 bits	1K loc * 2 per = 2K
	64, 24/40	1	10 (9:0)	1K loc * 1 per = 1K
DRAM Banks (A, B, C, or D)	32	2	20 (19:0) where bit 0 selects upper or lower 32 bits	512K loc * 2 per * 4 banks = 4M
	64, 24/40	1	20 (19:0)	1M loc * 1 per * 4 banks = 4M

The Counter Manager supports a special mode of operation when used by the Ingress or Egress Flow Control. This mode allows “delayed increments” to occur based on flow control information. Both Flow Controls pass an additional parameter, Flow Control Action, that causes the Counter Manager to modify which Counter Definition Entry is used. A standard enqueue sent by either Flow Control logic causes the Counter Manager to use the Counter Definition Index that is passed with the request. A discard resulting from the Transmit Probability table causes the Counter Manager to access the Counter Definition Entry that is located at Index+1. A Tail Drop Discard causes the Counter Manager to access the Counter Definition Entry located at Index+2. Each type of flow control action uses a different counter definition.

When the Policy Manager requests use of the Counter Manager, it always uses a Counter Definition Table Index of 0. This location is reserved for use by the Policy Manager.

The Counter Manager arbitrates for a new counter action at a rate of one each 15 ns. When accessing the internal memory, the Counter Manager can update these counters at a rate of one every 15 ns. The external DRAM rates are once each 150 ns or each 165 ns depending on DRAM cycle configuration (10- or 11-cycle windows), and one to four counters (one per bank) will be updated during this time. If the Counter Manager is updating some (but not all) DRAM banks, the banks not being updated by the Counter Manager will have their last location (address = all 1's) written during the DRAM write window. Therefore, the last location of each DRAM bank must be reserved for this use and cannot be assigned as a counter location.

The Counter Manager supports the following actions: read, read/clear, write/lower, write/upper, increment and add. The DPPUs can read any counter in the Counter Manager. The Flow Control and Policy Manager logic do not perform counter reads. When a counter is read, the Counter Manager returns the read data (either 32 or 64 bits) with the acknowledge signal. The picocode can also clear the counter (set to zero) after the read is performed by passing the Read/Clear action. Counter writes of 16 bits are supported and either bits 15:0 or bits 31:16 of the selected counter are set to the write value with all other bits set to zero (this feature is provided to assist in chaining unused counters into a free list).

The Counter Manager also supports incrementing or adding to the selected counter. The add value can be up to 16 bits in size and will be added to the counter (either 32, 40, or 64 bits). When a 24/40 counter is incremented or added, the 24-bit portion of the counter is incremented and the 40-bit portion receives the increment/add action.

The Counter Manager supports the following maximum numbers of counters (actual number depends on size of DRAM used and the Counter Definition Table information):

- Up to 1 K 64-bit, or 2 K 32-bit Internal Counters, or some mix of 64 and 32-bit counters not to exceed 64 Kb total size.
- Up to 1 M 64-bit, or 1 M 32-bit External Counters per DRAM Bank, or some mix of 64- and 32-bit counters not to exceed 1 M total counters per bank.

7.10 Semaphore Manager

The semaphore manager and coprocessor are available in NP4GS3B (R2.0). The semaphore manager is centrally located within the EPC and is controlled by a thread through a semaphore coprocessor.

A semaphore is a mechanism for acquiring ownership or “locking down” an entity. In this implementation a semaphore is a 32-bit value. once a thread has exclusive ownership of a semaphore, it is guaranteed that there are no other threads that own a semaphore with the same value (though there may be other threads owning semaphores with different values). Thus, other threads that also want ownership of a semaphore with the same value are blocked until the semaphore is unlocked.

It is upon the programmer to attach a meaning to a semaphore. That is, the semaphore manager does not know what a semaphore represents - it is just a string of 32 bits. Semaphores can be seen as having a 32-bit address space and the programmer can map this to anything, like the Tree Search Memory, the data store, or the Embedded PowerPC. For example, a tree search memory can have the upper four bits of the semaphore value set to ‘0000’, an ingress data store address can have the upper four bits of the semaphore value set to ‘0001’, and the embedded PowerPC mailbox may have the upper four bits set to ‘1111’.

In NP4GS3B (R2.0), when configured for ordered semaphores, a thread may have only one semaphore locked at a time. When the NP4GS3B (R2.0) is configured for unordered semaphores only, then a thread may have two semaphores (unordered) locked at a time.

- Unordered Semaphores - When multiple threads request a semaphore, the semaphore manager will grant the request through a round-robin fairness algorithm. A thread can lock-and-unlock an unordered semaphore as often as it wants. For example, it can lock-and-unlock, execute some code, lock again, execute more code, unlock, etc.
- Ordered Semaphores - When multiple threads request a semaphore, the semaphore manager will grant the request in the order of frame dispatch for a given flow. In other words, when a thread is processing a frame of a certain flow that has been dispatched before any other frames of the same flow, then it is guaranteed by the semaphore manager that this thread will get a certain semaphore value before any other threads that are processing frames of the same flow. The dispatch order will be maintained by placing a “reservation” into a queue. Only semaphore requests in which their reservation is on the top of the queue will be serviced. It will be the responsibility of the picocode to release a reservation if it isn’t needed or a deadlock situation will occur.

To use ordered semaphores, they must be enabled. This is done by writing the ordered semaphore enable register in the hardware classifier. There is one bit for the semaphore 0 ID queue, and one bit for the semaphore 1 ID queue. At dispatch time, the hardware classifier may assign a label to a frame as per the Port Configuration table. If a label is assigned, the hardware classifier will also look at the ordered semaphore enable register to see if ordered semaphores are enabled as well. If no labels are assigned, ordered semaphores will not be enabled. The label is treated as a 29-bit tag, allowing 2^{29} flows. The frame flow queue and the semaphore ordering queues use the same label. If a frame order label is released (via an enqueue with label or release label), the semaphore order label must first have either been used or released, otherwise an error will occur.

A thread can lock-and-unlock an ordered semaphore up to two times (this is an implementation restriction). During a request, the thread must specify the OrderID, which is 0 or 1. An order queue can only be used once, with two order queues implemented for a total of two ordered semaphores per thread. In other words, a thread can only lock OrderID 0 once, and OrderID 1 once.

Each thread can have ownership of up to two semaphores simultaneously. When using two semaphores, the programmer must take great care to avoid deadlock situations (semaphores can only be requested one by one). For example, a semaphore lock *must* be followed at some point by a semaphore unlock or a deadlock will occur.

The semaphore manager employs a pending concept to ordered semaphore lock requests, which enables it to look past the head of the completion unit queues. The basic idea is if a thread is requesting an ordered lock for a particular semaphore value that is already locked, it will be moved into a pending state, and it's request will not be considered complete. At this point, the threads that are behind it in the flow queues can now be considered for locking as long as their semaphore values are different. Once the original semaphore value that was locked is unlocked, then the pending thread's semaphore value will lock and that thread's request will be completed. It is important to note that only one thread per semaphore value will go into the pending state.

The semaphore manager will process the three semaphore coprocessor command types in parallel:

- Lock commands for ordered semaphores at the head of the queue and lock commands for unordered semaphores will be evaluated at the same priority level and a winner will be chosen using a round-robin fairness algorithm.
  - Lock commands will be evaluated in parallel with Unlock and Reservation Release commands.
- Unlock commands
  - Unlock commands will be evaluated in parallel with Lock and Reservation Release commands.
- Reservation Release commands
  - Reservation Release commands will be evaluated in parallel with Lock and Unlock commands.

8. Tree Search Engine

8.1 Overview

The Tree Search Engine (TSE) is a hardware assist that performs table searches. Tables in the network processor are maintained as Patricia trees, with the termination of a search resulting in the address of a leaf page. The format of a leaf page or object is defined by the picocode; the object is placed into a control store, either internal (H0, H1) or external (Z0, D0 - D3).

8.1.1 Addressing Control Store (CS)

References to the control store use a a 26-bit address as shown in *Table 8-1*. Each address contains a memory ID, a bank number, and address offset.

Table 8-1. Control Store Address Mapping for TSE References

26-bit Address Used to Reference the Control Store		
4 bits	2 bits	20 bits
Memory ID	Bank Number	Offset
Virtual Bank Address		

Table 8-2: CS Address Map and Use on page 295 provides addressing information and recommended uses for each memory that is supported by the CSA and that is accessible via the TSE. The memory type provides access width and memory size information. Selection for D0 as either single or double wide is by configuration (*13.1.2 DRAM Parameter Register (DRAM_Parm)* on page 440).

Table 8-2. CS Address Map and Use (Page 1 of 2)

Memory Id	Bank No.	Memory Name	Type	Offset width (bits)	Recommended Use
0000	00	Null		20	
	01-11	Reserved			
0001	00	Z0	External ZBT SRAM 512K x 36	19	Fast PSCB
	01-11	Reserved			
0010	00	H0	Internal SRAM 2K x 128	11	Fast Leaf pages
	01	H1	Internal SRAM 2K x 36	11	Fast internal SRAM
	10	Reserved			
	11	Reserved			
0011	00-11	Reserved			
0100 - 0111	00-11	Reserved			

Table 8-2. CS Address Map and Use (Page 2 of 2)

Memory Id	Bank No.	Memory Name	Type	Offset width (bits)	Recommended Use
1000	00-11	D0 banks A - D	DDR DRAM D0_Width = 0 8 MB 16 MB 32 MB D0_Width = 1 16 MB 32 MB 64MB	18 - 20	Single (D0_width = 0) or double wide (D0_width = 1) configuration. Leaf Pages
1001	00-11	D1 banks A - D	DDR DRAM 8 MB 16 MB 32 MB	18 - 20	Leaf Pages
1010	00-11	D2 banks A - D			Leaf or Counter pages
1011	00- 1	D3 banks A - D			DT entries and PSCB entries
1100	00- 1	D6 banks A - D	DDR DRAM 8 MB (R2.0) 16 MB (R2.0) 32 MB 64MB 128 MB	20	PowerPC external memory
1101					
1110					
1111					
Note: DDR DRAM is specified as: Number of banks x number of entries x burst access width (in bits).					

8.1.2 D6 Control Store.

The NP4GS3 supports the following DDR DRAM types for the D6 control store:

DDR DRAM	Total memory space (MB)	Notes
4x1Mx16 x1chip	8	1
4x2Mx16 x1chip	16	1
4x4Mx4 x4 chips	32	
4x4Mx16 x1chip	32	1
4x8Mx4 x4 chips	64	
4x16Mx4 x4chips	128	
Note: 1. NP4GS3B (R2.0) or later		

The D6 control store can be accessed either via the TSE or by the embedded PowerPC's Processor Local Bus (PLB) (see *10.2 Processor Local Bus and Device Control Register Buses* on page 366).

8.1.3 Logical Memory Views of D6

Using the PLB, the embedded PowerPC or a PCI attached host views a flat, contiguous address space addressable on byte boundaries.

Access via the TSE uses the Control Store address mapping described in *8.1.1 Addressing Control Store (CS)* on page 295, and is composed of a Memory ID, Bank Number and offset. The offset limits addressing capability to 8-byte boundaries within the DDR DRAM.

Table 8-3 illustrates the PLB to D6 control store address translation. The PLB address is shown within the body of the table and the D6 control store address is formed using the Memory ID, Bank Number, and Offset.

Table 8-3. PLB and D6 Control Store Addressing

Memory ID (4 bits)	Bank A ('00')	Bank B ('01')	Bank C ('10')	Bank C ('11')	Offset (20 bits)
'1100'	0-7	8-x'F	x'10-x'17	x'18 - x'1F	x‘00 0000’
	x'20-x'27	x'28-x'2F	x'30-x'37	x'38-x'3F	x‘00 0001’
	x'07F FFE0 - x'07F FFE7	x'07F FFE8 - x'07F FFEF	x'07F FFF0 - x'07F FFF7	x'07F FFF8 - x'07F FFFF (8MB-1)	x‘03 FFFF’
	x'0FF FFE0 - x'0FF FFE7	x'0FF FFE8 - x'0FF FFEF	x'0FF FFF0 - x'0FF FFF7	x'0FF FFF8 - x'0FF FFFF (16MB-1)	x‘07 FFFF’
	x'1FF FFE0 - x'1FF FFE7	x'1FF FFE8 - x'1FF FFEF	x'1FF FFF0 - x'1FF FFF7	x'1FF FFF8 - x'1FF FFFF (32MB-1)	x‘0F FFFF’
'1101'	x'200 0000 - x'200 0007	x'200 0008 - x'200 000F	x'200 0010 - x'200 0017	x'200 0018 - x'200 001F	x‘00 0000’
	x'3FF FFE0 - x'3FF FFE7	x'3FF FFE8 - x'3FF FFEF	x'2FF FFF0 - x'2FF FFF7	x'3FF FFF8 - x'3FF FFFF (64MB-1)	x‘0F FFFF’
	x'400 0000 - x'400 0007	x'400 0008 - x'400 000F	x'400 0010 - x'400 0017	x'400 0018 - x'400 001F	x‘00 0000’
	x'5FF FFE0 - x'5FF FFE7	x'5FF FFE8 - x'5FF FFEF	x'5FF FFF0 - x'5FF FFF7	x'5FF FFF8 - x'5FF FFFF (96MB-1)	x‘0F FFFF’
'1111'	x'600 0000 - x'600 0007	x'600 0008 - x'600 000F	x'600 0010 - x'600 0017	x'600 0018 - x'600 001F	x‘00 0000’
	x'7FF FFE0 - x'7FF FFE7	x'7FF FFE8 - x'7FF FFEF	x'7FF FFF0 - x'7FF FFF7	x'7FF FFF8 - x'7FF FFFF (128MB-1)	x‘0F FFFF’

D6 control stores implemented in DDR DRAM of up to 32 MB in size are accessed by the TSE using only Memory ID '1100'. Larger D6 control stores require Memory IDs of '1101' (up to 64 MB), '1110' (up to 96 MB) and '1111' (up to 128 MB).

A method to share memory objects between the embedded PowerPC or attached PCI host using the PLB, and picocode running on the NP4GS3 using TSE instructions is to specify the object (as viewed by the TSE) with a height of one and a width of four. This allows the TSE access to all of the D6 control store, on 32-byte boundaries, and is consistent with the PLB's flat contiguous address space view. Successive objects with a height of one and a width of four are accessed by incrementing the TSE address until a 32MB boundary is reached. At the boundary it is necessary to increment the Memory ID to address the next successive object.

8.1.4 Control Store Use Restrictions

The following restrictions apply:

- When D2 is used by the counter manager, the last location (highest address) in each bank must not be assigned for any use.
- DT entries can be stored only in H1, Z0, or D3.

  For NP4GS3A (R1.1), LPM DT entries are restricted to D3 only.
- PSCBs can be stored only in H1, Z0, or D3.
- Leaf pages can be stored only in H0, D0, D1, and D2.

8.1.5 Object Shapes

Object shapes specify how the control store stores an object such as a leaf or pattern search control block (PSCB). A leaf is a control block that contains the reference key as a reference pattern. The pattern uniquely identifies the leaf in a tree and contains the data needed by the application initiating a tree search. The data is application-dependent, and its size or memory requirements are defined by the LUDefTable entry for the tree. See *Table 8-5: Height, Width, and Offset Restrictions for TSE Objects on page 301* and *Table 8-17. LUDefTable Entry Definitions* on page 312 for details.

Shape is defined by two parameters, height and width. Objects small enough to fit within a single memory or bank location are defined as having a height and width of 1 (denoted by 1,1), and therefore do not require shaping. For example, both a 32-bit and a 48-bit object stored in a DDR SDRAM bank would have a shape of (1,1).

Table 8-4. DTEntry, PSCB, and Leaf Shaping

Object	Shape
FM DTEntry/PSCB	Always has a shape of height = 1, width = 1.
SMT DTEntry/PSCB	Always has a shape of height = 1, width = 1.
LPM DTEntry/PSCB	Has a shape of height = 1, width = 1 or height = 2, width = 1 depending on the memory in which the PSCB resides. A memory with a line width of at least 64 bits should be used with height = 1 and a memory of 36 bits should be used with height = 2.
Leaf	Can have any shape that is allowed by the memory in which the leaf is located - maximum of 512 bits.

When objects do not fit into a single memory or bank location, they have heights and/or widths > 1:

- Height denotes the number of consecutive address locations in which an object is stored. For example, if the height of an object = 4 and the control store address = A, the object is stored in locations A, A+1, A+2, and A+3.
- Width denotes the number of consecutive banks in which the object is stored. Width always = 1 for objects stored in ZBT SRAM, and could be > 1 for objects in DDR SDRAM. For example, if the width of an object = 3, and its height = 1, the object is stored in three consecutive banks (the virtual bank address is incremented by 1).
- An offset increment can carry out into the bank address bits. This is not a supported use of the CS memory, and table allocation algorithms must be defined to avoid this condition.

- For height and width, the hardware automatically reads the appropriate number of locations. From a picocode point of view, an object is an atomic unit of access. Restrictions to height, width, and offset are given in *Table 8-5: Height, Width, and Offset Restrictions for TSE Objects on page 301*. *Table 8-17: LUDefTable Entry Definitions* on page 312 specifies the leaf and PSCB shapes.

Figure 8-1. Example Shaping Dimensions on page 300 illustrates some example placement of objects with different shapes in control store. An object may span more than one DRAM as shown in examples (b) and (c) with the following restrictions:

- An object may span D1 and D2.
- When D0 is configured as a single wide (D0_Width = 0), then an object may span D0 and D1.
- Objects may not span out of D0 when D0 is configured as a double wide (D0_Width = 1).
- Objects may not span into or out of Z0, H0, H1, D3 or D6.
- Shape object can define a maximum of 512 bits for any memory.

Figure 8-1. Example Shaping Dimensions

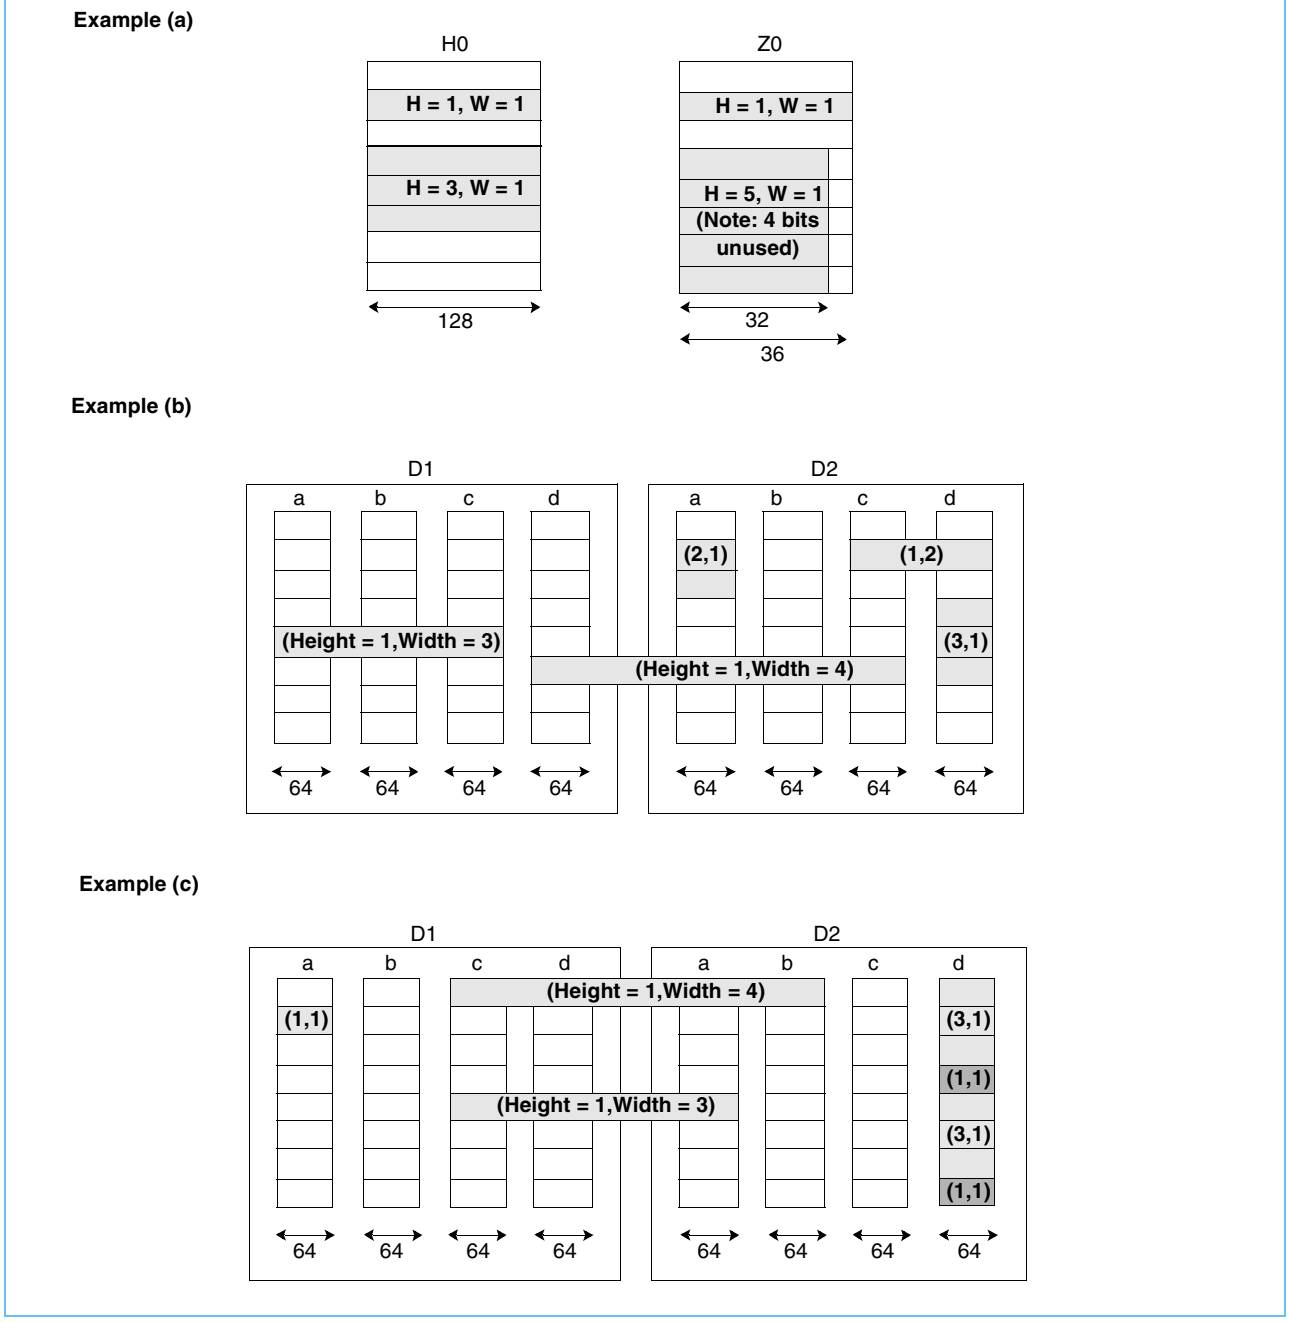


Table 8-5. Height, Width, and Offset Restrictions for TSE Objects

Memory	Height	Width	Total Object Size (bits)	Control Store Address Offset Must Be Divisible By
H0	1 2 3 4	1 1 1 1	128 256 384 512	1 2 4 4
H1	1 2 3 4 5 6 7 8	1 1 1 1 1 1 1 1	36 64 96 128 160 192 224 256	1 2 4 4 8 8 8 8
Z0	1 2 3 4 5 6 7 8	1 1 1 1 1 1 1 1	36 64 96 128 160 192 224 256	1 2 4 4 8 8 8 8
D0 (D0_Width = 1; double wide configuration)	1 2 3 4 1 2 1 1	1 1 1 1 2 2 3 4	128 256 384 512 256 512 384 512	1 2 4 4 1 2 1 1
D0-D1-D2-D3-D6 (D0_Width = 0; single wide configuration)	1 2 3 4 5 6 7 8 1 2 3 4 1 2 1 2	1 1 1 1 1 1 1 1 2 2 2 2 3 3 4 4	64 128 192 256 320 384 448 512 128 256 384 512 192 384 256 512	1 2 4 4 8 8 8 8 1 2 4 4 1 2 1 2

8.1.6 Illegal Memory Access

When the TSE uses an undefined MemoryID (that is, reserved) or an illegal memory shape, the TSE aborts the current command, returns a KO status, and sets an exception flag at bit 2 in interrupt class 3 (TSM_Illegal_Memory_Access). The exception flag can be set to cause an interrupt by setting bit 2 of interrupt mask 3 to ‘1’ (TSM_Illegal_Memory_Access). For debugging purposes, an exception can switch a programmable set of threads into single-step mode.

8.1.7 Memory Range Checking (Address Bounds Check)

Memory range checking can flag access to a programmable range within Min_addr_Bounds and Max_addr_Bounds for read, write or both using Addr_Bounds_Cntl. Min_addr_Bounds. Memory range checking can be performed for any TSE Control Store accesses only. When memory range checking is enabled, any Control Store read, write, or read/write address falling outside the defined range, generates an exception (an exception does not stop TSE operation) and sets an exception flag at bit 1 in interrupt class 3 (TSM_Addr_Range_Violation). The exception flag can be set to cause an interrupt by setting bit 1 of interrupt mask 3 to ‘1’ (TSM_Addr_Range_violation). For debug purpose, Bounds Violation Register (Bounds_vio), indicates which GxH has caused an address bounds exception.

8.2 Trees and Tree Searches

The TSE uses trees to store and retrieve information. Tree searches, retrievals, inserts and deletes are performed according to a key that is similar to a MAC source address or a concatenation of an IP source and destination address. Information is stored in one or more leaves that contain the key as a reference pattern and, typically, contain aging and user information for forwarding purposes such as target blade and target port numbers.

To locate a leaf, a search algorithm processes input parameters that include the key and hashes the key. The algorithm then accesses a direct table (DT) and walks the tree through the PSCBs. There are three types of trees, each with its own search algorithm and tree-walk rules: full match (FM); longest prefix match (LPM); and software managed (SMT).

The data structure of FM and LPM trees is the Patricia tree. When a leaf is found, the leaf is the only candidate that can match the input key. A “compare-at-end” operation compares the input key with a reference pattern stored in the leaf to verify a match. Search results are “OK” when a match is found and “KO” in all other cases.

The data structure of SMT trees is similar to that of FM trees, but SMT trees can have multiple leaves that can be chained in a linked list. All leaves in the chain are checked against the input key until a match is found or the chain is exhausted. Search results are “OK” when a match is found and “KO” in all other cases.

Table 8-6. FM and LPM Tree Fixed Leaf Formats

Field Name	Byte Length	Description
NLARope	4	Leaf chaining pointer, aging, and direct leaf information
Prefix_Len	1	Length of the pattern (in bits) for LPM only. Not used by TSE for FM trees and can be used by picocode.
Pattern	2-24	Pattern to be compared with HashedKey. Always present. Length given by P1P2_max_size from *Table 8-17: LUDefTable Entry Definitions* on page 312. For FM: Unused bit between (p1p2_max_size - Hashedkey_length) must be initialize to zero. For LPM: Unused bits between (p1p2_max_size - Prefix_Len), do not have to be initialized and can be used by user data since these bits do not take part in comparsion.
UserData	Variable	Under picocode control. For example, field can include one or more counters.

Table 8-7. SMT Tree Fixed Leaf Formats

Field Name	Byte Length	Description
NLASMT	4	Leaf chaining pointer to chain leaves for SMT. Includes shape of chained leaf.
Comp_Table_Index	1	Defines index in CompDefTable that defines compare between Pattern1, Pattern2, and HashedKey.
Pattern1 and Pattern2	4-48	Contains Pattern1 and Pattern2 bitwise interleaved (even bits represent Pattern1 and odd bits represent Pattern2). That is, bit 0 of the field contains bit 0 of Pattern1, bit 1 contains bit 0 of pattern 2, etc. Length given by 2*P1P2_Max_Size from *Table 8-17: LUDefTable Entry Definitions* on page 312. For SMT: Unused bit between (2 * p1p2_max_size - 2 * Hashedkey_length) must be initialized to zero.
UserData	Variable	Under picocode control. For example, field can include one or more counters.

Table 8-8. Search Input Parameters

Parameter	Bit Length	Description
Key	192	Key must be stored in the Shared Memory Pool. All 192 bits must be set correctly (for Key Length shorter than 192, remaining bits in Shared Memory Pool must be set to 0).
Key Length	8	Contains Key Length minus 1 in bits.
LUDefIndex	8	Index into LUDefTable that points to an entry containing a full definition of the tree in which the search occurs. See section *8.2.5.1 The LUDefTable* on page 312.
TSEDPA	4	TSE Thread Shared Memory Pool Address - stores location of Key, KeyLength, and Color and determines Leaf destination. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', x'A', x'C', and x'E'.
LCBANr	1	Search results can be stored in either TSRx, as specified by TSEDPA. Leaf addresses are stored in LCBA0 or LCBA1 as specified by LCBANr. During a TSE search, picocode can access the other TSR to analyze the results of previous searches.
Color	16	For trees with color enabled, as specified in the LUDefTable, the contents of the color register are inserted into the key during hash operation. See section *8.2.1 Input Key and Color Register for FM and LPM Trees* on page 304 for an explanation of the process.

8.2.1 Input Key and Color Register for FM and LPM Trees

For FM and LPM trees, the input key is hashed into a HashedKey according to the hash algorithm specified by the Hash_type field in the LUDefTable. To minimize the depth of the tree that begins after the direct table, the hash function output is always a 192-bit number with a one-to-one correspondence to the original input key. Maximum output entropy is contained in the hash function's most significant bits. The N highest bits of the HashedKey register are used to calculate an index into the direct table, where N is determined by the definition of the DT (Direct Table) entry for the tree.

When colors are enabled for a tree, the 16-bit color register is inserted after the input key has been hashed. This occurs immediately after the direct table. If the direct table contains 2^N entries, the 16-bit color value is inserted at bit position N. The hash function output and the inserted color value (when enabled) are stored in the HashedKey register. When colors are disabled, the 192-bit hash function is unmodified.

Colors can be used to share a single direct table among multiple independent trees. For example, color could indicate a VLANID in a MAC source address table. The input key would be the MAC SA and the color the VLANID (VLANID is 12 bits and 4 bits of the color would be unused, that is, set to 0). After the hash function, the pattern would be 48 + 16, or 64 bits. The color would be part of the pattern to distinguish MAC addresses of different VLANs.

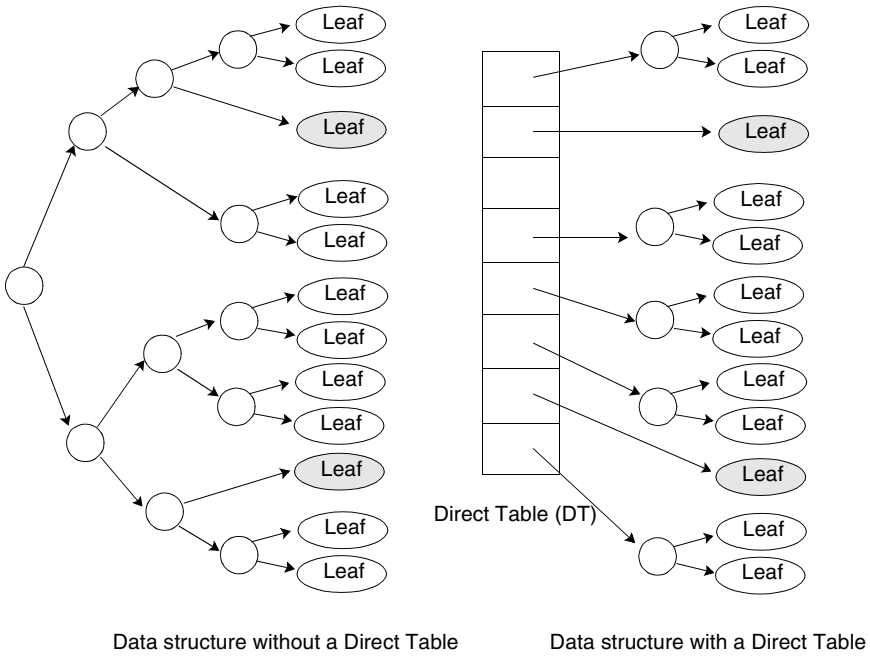
8.2.2 Input Key and Color Register for SMT Trees

For SMT trees, the input key is a 192-bit pattern and the color register is ignored. No hashing is performed.

8.2.3 Direct Table

A search starts when a DTEntry is read from the direct table. The read address is calculated from the N highest bits of the HashedKey and from the tree properties defined in the LUDefTable. The DTEntry can be represented as the root of a tree, with the actual tree data structure depending upon tree type. A Patricia tree data structure is used with FM trees. Extensions to the Patricia tree are used with LPMs and SMTs. Using a DT can reduce search time (PSCB access time). Increasing DT size is a trade-off between memory usage and search performance. When a single leaf is attached to a DTEntry, the read data includes a pointer to the leaf. When more than one leaf is attached, the read data defines the root of a tree. When the DTEntry is empty, no leaf information is attached.

Figure 8-2. Effects of Using a Direct Table



8.2.3.1 Pattern Search Control Blocks (PSCB)

A search begins when a DTEntry has been read if the DTEntry is neither empty nor contains a direct leaf. A tree walk search starts at the DTEntry and passes one or more PSCBs until a leaf is found. For an FM tree, the PSCB represents a node in the tree, or the starting point of two branches, “0” and “1”. Each PSCB is associated with a bit position “p” in the HashedKey. Bit p is the next bit to test (NBT) value stored in the previous PSCB or in the DTEntry. Leaves reachable from a PSCB through the 0 branch have a ‘0’ in bit p, and leaves reachable through the 1 branch have a ‘1’. Leaves reachable through either branch have patterns where bits 0..p-1 are identical, because pattern differences begin at bit p.

When an FM tree search encounters a PSCB, the TSE continues the tree walk on the 0 or 1 branch depending on the value of bit p. Thus, PSCBs are only inserted in the tree at positions where leaf patterns differ. This allows efficient search operations since the number of PSCBs, and thus the search performance, depends on the number of leaves in a tree, not on the length of the patterns.

8.2.3.2 Leaves and Compare-at-End Operation

The entire HashedKey is stored in the leaf as a reference pattern, not as the original input key. During a tree walk, only the HashedKey bits for which a PSCB exists are tested. When an FM leaf is found, its reference pattern must be compared to the full HashedKey to make sure all the bits match. For SMT, if the leaf contains a chain pointer or NLA field to another leaf, the new leaf's reference pattern is compared to the HashedKey. Lacking a match or another NLA field, the search ends and the failure is indicated by a KO status. If the pattern matches, the original input key is checked. If that matches, the whole leaf page is returned to the network processor. If there is no match, the leaf page is returned with a no-match message.

8.2.3.3 Cascade/Cache

The direct table can be used as a cache to increase tree search performance since these trees are generally small and contain most likely entries. During a search, the TSE first determines whether the DT contains a pointer to a leaf matching the HashedKey. If so, the leaf is returned, eliminating the need for a search. To the TSE, a cache lookup is identical to a normal search, that is, the input key is hashed into a HashedKey and the DT is accessed.

Cascades/caches are enabled in the LUDefTable on a per-tree basis. If a cache search uses LUDefTable entry I and the search ends with KO, another search using LUDefTable entry I+1 starts automatically. This allow multiple search chaining, although the full tree should be stored under LUDefTable entry I+1. Cascading/caching of more than one LUDefTable entry is not supported in the current design, therefore the LUDefTable entry I + 1 must have the cache enable bit set to '0' (i.e., disabled). Also, whenever Cascade/cache is enabled, the UseLuDefCopyReg operand option for GTH should be set to '0' for current version of the device.

8.2.3.4 Cache Flag and NrPSCBs Registers

Picocode initiates insert and delete operations to and from the cache. Each search result stores information about the cache in the CacheFlag and NrPSCBs registers as shown in *Table 8-9*. Each register is divided into two sections, one for searches using TSE 0 coprocessor and the other for searches using TSE 1 coprocessor. There are two copies of these registers for each TSE 0 and TSE 1 resource.

Table 8-9. Cache Status Registers

Register	Bit Length	Description
CacheFlag(0)	1	CacheEmpty bit. Set when cache search finds an empty DTEntry in cache DT.
CacheFlag(1)	1	CacheLeafFound bit. Set when cache search finds a leaf and cache search returns OK. When leaf found bit has been set, full search has not been performed.
CacheFlag(2)	1	CacheKO bit. Set when cache search returns KO. When cache is empty, this bit is also set.
NrPSCBs	8	After any search, contains the number of PSCBs read during a tree walk. When a cache search finds no leaf and a full search starts, contains the number of PSCBs read during the search.

8.2.3.5 Cache Management

Cache management is performed using picocode. Cache inserts are controlled by inspecting the CacheFlag and NrPSCBs registers after each tree search. Inserts are treated like normal FM tree inserts, allowing the association of multiple leaves with a single DTEntry, because normal FM inserts create PSCBs to handle multiple leaves. Inserts can also be done by writing directly to a DTEntry, although only using single leaves. Cache deletes use the tree aging mechanism whereby every N seconds all entries in the cache are deleted.

8.2.3.6 Search Output

The output of a search operation consists of the parameters listed in *Table 8-10*.

Table 8-10. Search Output Parameters

Parameter		Description
OK/KO flag		0 KO: Unsuccessful Operation 1 OK: Successful Operation that is, leaf pattern matches HashedKey
TSRx	Shared memory pool	Leaf contents are stored at TSEDPA address of the shared memory pool, specified by the tree search command operand.
LCBA0 / 1	Scalar registers	Leaf address is stored in LCBA0 / 1 based on LCBANr input value.
CacheFlags(2)		CacheEmpty bit
CacheFlags(1)		CacheLeafFound bit
CacheFlags(0)		CacheKO bit
NrPSCBs		Number of PSCBs read during last search. Can be used as a criterion to insert FM cache entry.

8.2.4 Tree Search Algorithms

The TSE provides hardware search operations for FM, LPM, and SMT trees. Software initializes and maintains trees. Leaves can be inserted into and removed from FM and LPM trees without control point function (CPF) intervention, permitting scalable configurations with CPF control when needed.

8.2.4.1 FM Trees

Full Match (FM) trees provide a mechanism to search tables with fixed size patterns, such as a Layer 2 Ethernet Unicast MAC tables which use fixed six-byte address patterns. Searches of FM trees are efficient because FM trees benefit from hash functions. The TSE offers multiple fixed hash functions that provide very low collision rates.

Each DTEntry is 36 bits wide and contains the formats listed in *Table 8-11*. PSCBs have the same structure as DTEntrys except they contain two PSCBLines, each of which can have one of the two pointer formats listed in this table*: Next Pointer Address (NPA) or Leaf Control Block Address (LCBA)*. The two PSCBLines are allocated consecutively in memory and are used as walking branches in the tree. The NBT value signifies which of the two PSCBLines is used.

Table 8-11. DTEntry and PSCBLine Formats

Format	Conditions	Valid in DTEntry?	Valid in PSCB?	Format (2 bits)	NPA/LCBA (26 bits)	NBT (8 bits)
Empty DTEntry	No leaves	Yes	No	00	0	0
Pointer to next PSCB	DTEntry contains pointer	Yes	Yes	00	NPA	NBT
Pointer to leaf	Single leaf associated with DTEntry; LCBA field contains pointer	Yes	Yes	01	LCBA	0

8.2.4.2 LPM Trees

Longest Prefix Match (LPM) trees provide a mechanism to search tables with variable length patterns or prefixes, such as a Layer 3 IP forwarding table where IP addresses can be full match host addresses or prefixes for network addresses. The CPF manages LPM trees with assistance from the GTH for inserting and removing leaf entries. LPM DTEntrys, each of which can contain a node address, an NPA, and an LCBA, differ from FM DTEntrys which cannot contain both a node and leaf address.

Each DTEntry is 64 bits wide and contains the formats listed in *Table 8-12: LPM DTEntry and PSCBLine Formats* on page 308. PSCBs have the same structure as DTEntrys except PSCBs contain two PSCBLines, each of which can have one of the three LCBA formats listed in the table. The two PSCBLines are allocated consecutively in memory and are used as walking branches in the tree. One of the PSCB lines may be empty, which is not allowed in FM PSCBs.

Table 8-12. LPM DTEntry and PSCBLine Formats

Format	Conditions	Valid in DTEntry?	Valid in PSCB?	Format (2 bits)	NPA (26 bits)	NBT (8 bits)	LCBA (26 bits)	Spare (2 bits)
Empty DTEntry	No leaves	Yes	Yes	00	0	0	0	0
LCBA not valid	DTEntry contains pointer to PSCB	Yes	Yes	00	NPA	NBT	0	0
LCBA valid; NPA/ NBT not valid	Single leaf associated with DTEntry; LCBA contains pointer to leaf; No pointer to next PSCB	Yes	Yes	01	0	0	LCBA	0
LCBA valid; NPA/ NBT valid	Single leaf associated with DTEntry; LCBA contains pointer to leaf; Pointer to next PSCB	Yes	Yes	01	NPA	NBT	LCBA	0

8.2.4.3 SMT Trees

Software-managed (SMT) trees provide a mechanism to create trees that follow a Control Point Function (CPF)-defined search algorithm such as an IP quintuple filtering table containing IPSA, IPDA, source port, destination port, and protocol. SMT trees use the same PSCBs as FM trees, but only the first leaf following a PSCB is shaped by the *Table 8-17: LUDefTable Entry Definitions* on page 312. The following leaves in a leaf chain are shaped according to the five bits in the chaining pointer contained in the NLASMT leaf field (see *Table 8-13*). Unlike FM and LPM, SMT trees allow leaves to specify ranges, for instance, that a source port must be in the range of 100..110. SMT trees always contain two patterns of the same length in a leaf to define a comparison range. When the first leaf is found after a PSCB, a compare-at-end operation is performed. If OK, the search stops. If the comparison returns KO and the NLASMT field is non-zero, the next leaf is read and another compare-at-end operation is performed. This process continues until an “OK” is returned or until the NLASMT field is zero, which returns a KO.

Table 8-13. NLASMT Field Format

1 bit	2 bits	3 bits	26 bits
Reserved	Width of next leaf	Height of next leaf	NLA (Next Leaf Address)

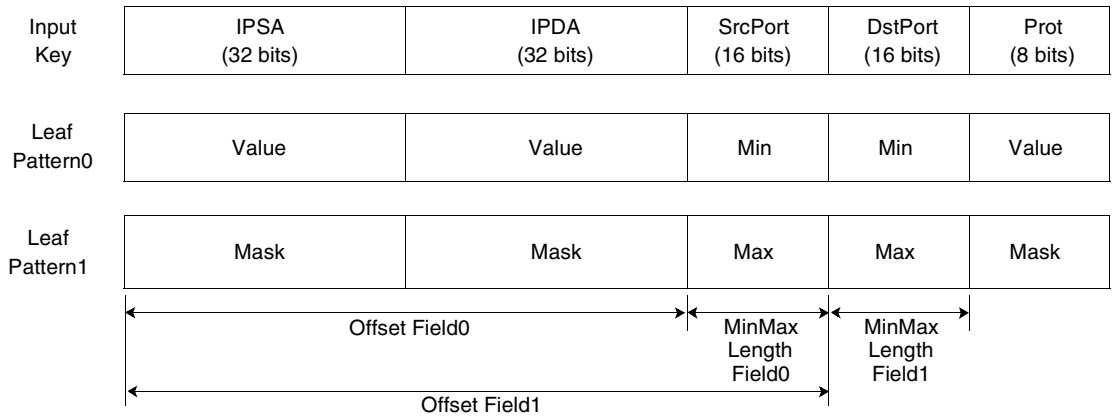
8.2.4.4 Compare-at-End Operation

The input key and the two reference patterns stored in each leaf can be logically divided into multiple fields (see *Figure 8-3* on page 309). One of two comparisons can be performed on each field:

1. Compare under mask. The input key bits are compared to Pattern0 bits under a mask specified in Pattern1. A '1' in the mask means the corresponding bit in the input key must equal the corresponding bit in Pattern0. A '0' means the corresponding bit in the input key has no influence on the comparison. The entire field matches only when all bits match, in which case the TSE returns OK.
2. Compare under range. The input key bits are treated as an integer and checked to determine whether the integer is within the range specified by Min and Max, inclusive. If so, the TSE returns OK, otherwise the TSE returns KO.

When all fields return OK, the entire compare-at-end returns OK. Otherwise, KO returns. This operation uses CompTableDef for definition and type of compare indication.

Figure 8-3. Example Input Key and Leaf Pattern Fields



Logical field definitions are specified in the compare definition table CompDefTable. *Table 8-14* shows the entry format for the CompDefTable. Fields are compare-under-mask unless specified by the CompDefTable. Each entry specifies one or two range comparisons, although multiple entries can specify more than two range comparisons. Each range comparison is defined by offset and length parameters. The offset, which is the position of the first bit in the field, must be at a 16-bit boundary and have a value of 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 174, or 192. The length of the field must be 8, 16, 24, or 32 bits.

Table 8-14. CompDefTable Entry Format

Field	Range	Bit Length	Value
Range 1 Offset (R1_Offset)	1	8	Starting bit position for first range compare. It is defined by compare_table(35 to 28) bits but only 4 upper bits are used to define the offset i.e (bits 35 to 32) and bits (31 to 28) are ignored. Therefore, this field must be in 16 bit boundary
Range 1 Length (R1_Len)	1	8	Length and number of bits to be used as a part of range compare starting/ beginning from R1_Offset.This field is specified as the number of bits multiplied by 4. It is defined by compare_table(27 to 20) bits, but only 3 MSBs are used to define the length (i.e. bits 27,26 & 25) and bits 24 to 20 are ignored.
Range 2 Offset (R2_Offset)	2	8	Starting bit position for second range compare. It is defined by compare_table(19 to 12) bits but only 4 upper bits are used to define the offset; i.e bits 19 to 16 and bits 15 to 12 are ignored. Therefore, this field must be in 16-bit bound.
Range 2 Length (R2_Len)	2	8	Length and number of bits to be used as a part of range compare starting/ beginning from R2_Offset. This field is specified as the number of bits multiplied by 4. It is defined by compare_table(11 to 4) bits but only 3 MSBs are used to define the length (i.e. bits 11 to 9) and bits (8 to 4) are ignored.
Range 2 Valid (R2_Valid)	--	1	Range 2 Valid value. This field indicates whether or not the Range 2 Offset and Length fields are valid. 0 Range 1 Offset and Length valid, but Range 2 Offset and Length not valid. 1 Range 1 and Range 2 Offset and Length all valid. It is defined by compare_table(3) bit.
Continue (Cont)	--	1	Continue indicator value. This field indicates whether the compare operation is continued in the next sequential entry of the table. 0 Comparison not continued 1 Comparison continued It is defined by compare_table(2) bit.

In the input key shown in *Figure 8-3: Example Input Key and Leaf Pattern Fields* on page 309, the compare-under-range for the Source Port (SrcPort) field would have Offset0 set to 64 and MinMaxLength0 set to 16. The compare-under-range for the Destination (DstPort) field would have Offset1 set to 80 and MinMaxLength1 set to 16. If more than two range comparisons are required, the Continue bit would be set to 1 so the next CompDefTable entry could be used for additional compare-under-range definitions.

The CompDefTable index used for tree comparisons is specified in the leaf Comp_Table_Index field (see *Table 8-7: SMT Tree Fixed Leaf Formats* on page 303). Each compare-under-range operation takes one clock cycle, so use as few compare-under-range operations as possible. If a range is a power of two, or 128-255, no compare-under-range is required since this range can be compared using compare-under-mask. When a compare-at-end fails and the SMTNLA leaf field is not 0, the TSE reads the next leaf and performs additional compare-at-end operations until the compare returns OK or until the SMTNLA is 0.

8.2.4.5 Ropes

As shown in the following figure, leaves in a tree can be linked together in a circular list called a rope. The first field in a leaf is the chaining pointer, or the NLARope. Picocode can “walk the rope,” or sequentially inspect all leaves in a rope. Ropes can be created by setting the NLARope_En bit to ‘1’ in the LUDefTable. See *Table 8-15: LUDefTable Rope Parameters* on page 311.

Figure 8-4. Rope Structure

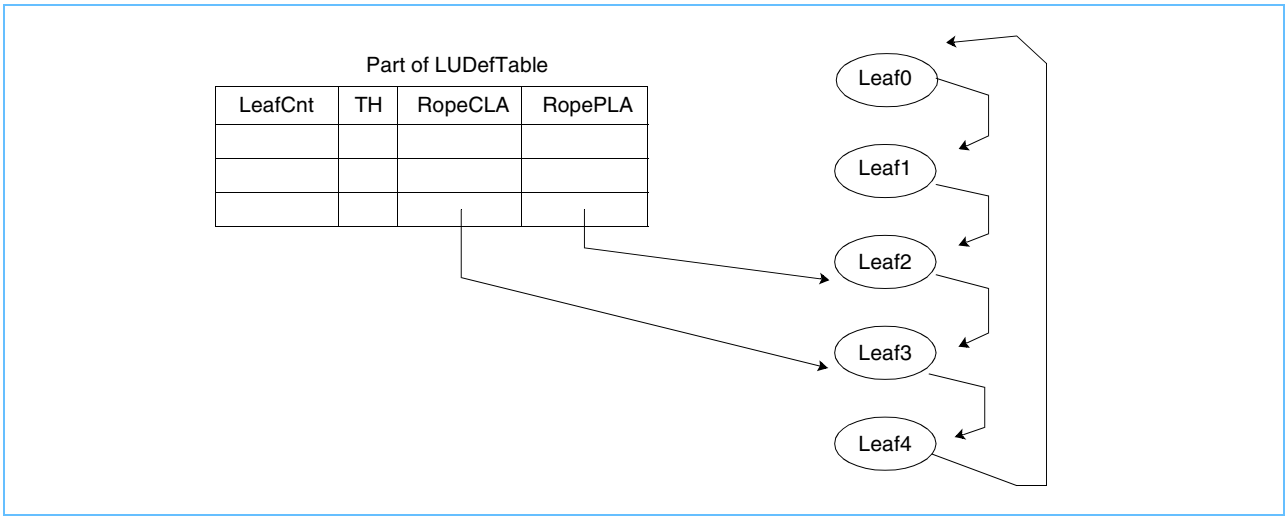


Table 8-15. LUDefTable Rope Parameters

Parameter	Description
RopeCLA	Current leaf address in the rope. All TSE instructions related to the rope such as RCLR, ARDL and TLIR (see section *8.2.8 GTH Hardware Assist Instructions* on page 336) relate to the leaf addressed by RopeCLA.
RopePLA	Previous leaf address in the rope. Always the previous leaf if the rope is related to RopeCLA unless the rope contains no leaf or one leaf. The following condition is always true for trees with two or more leaves: RopePLA -> NLARope == RopeCLA.
LeafCnt	Leaf count - number of leaves in the tree
LeafTh	Leaf threshold causes an exception to be generated when the LeafCnt exceeds the threshold.

Leaf insertion is always done between a RopeCLA and RopePLA. After insertion, the RopePLA is unchanged and the RopeCLA points to the newly inserted leaf.

Leaf deletion is done two ways:

1. When the rope is not being walked, the rope is a single-chained linked list without a previous pointer. Leaves cannot be deleted without breaking the linked list. Setting the DeletePending bit postpones the deletion until the rope is walked again. A leaf is deleted by setting the DeletePending bit of the NLARope field. In this case, leaves are completely deleted and leaf pattern searches will return a KO.
2. When the rope is being walked and the DeletePending bit is set, the TSE deletes the leaf automatically.

8.2.4.6 Aging

Aging is enabled whenever a rope is created. The NLARope field contains one aging bit that is set to ‘1’ when a leaf is created. When a leaf that matches the leaf pattern is found during a tree search, the TSE sets the aging bit to ‘1’ if it has not previously done so, and then writes this information to the control store. An aging function controlled by a timer or other device can walk the rope to delete leaves with aging bits set to ‘0’ and then write the leaves to the control store with aging bits set to ‘0’. When no aging is desired, picocode should not alter the aging bit, since bits set to ‘1’ cannot be changed.

Table 8-16. NLARope Field Format

2 bits	1 bit	2 bits	1 bit	26 bits
Reserved	Aging Counter	Reserved	Delete Pending	NLA (Next Leaf Address)

8.2.5 Tree Configuration and Initialization

8.2.5.1 The LUDefTable

The lookup definition table (LUDefTable), an internal memory structure that contains 128 entries to define 128 trees, is the main structure that manages the control store. The table indicates in which memory (DDR-SDRAM, SRAM, or internal RAM) trees exist, whether caching is enabled, key and leaf sizes, and the search type to be performed. Each DTEntry contains two indexes to the Pattern Search and Leaf Free Queue (PSCB_Leaf_FQ). The first index defines which memory to use to create tree nodes, that is, where PSCBs are located. The second defines which memory to use to create leaves within a tree. When an entry is added to a tree, the memory required for the insert comes from the PSCB_Leaf_FQ and is returned when the entry is deleted. For SMT trees, an LU_Def_Tbl can be defined to match a value into a given range, but an index to an internal Compare Type Index must be given for the Compare Table (Cmp_Tbl).

Table 8-17. LUDefTable Entry Definitions (Page 1 of 3)

Field	Bit Length	Description
Cascade_entry/ Cache_entry	1	0 Normal tree entry (not a cache entry) 1 A Cascade/cache entry. When a search returns with KO, and Cache_entry = 1, TS instructions will restart using the next entry in the LUDefTable (that is, LUDefIndex + 1). Special Note: LUDefIndex +1 entry must have this bit set to '0' (i.e., disabled).
Search_Type	2	Search Type value. This field indicates the type of search to be performed. 00 Full Match (FM). 01 Longest Prefix Match (LPM). 10 Software Managed Tree Longest Prefix Match (SMT LPM). 11 Reserved.
Hash_Type	4	Hash type 0000 No Hash 0001 192-bit IP Hash 0010 192-bit MAC Hash 0011 192-bit Network Dispatch Hash 0100 No Hash 0101 48-bit MAC Swap 0110 60-bit MAC Swap 0111 Reserved 1000 8-bit Hash 1001 12-bit Hash 1010 16-bit Hash Special Note: When using Hash_Type 1000, 1001, and 1010, Hashedkey and HashedKey_length will be extended by 8, 12, or 16 bits, respectively.
Color_En	1	Color Enable control value. This field controls whether the Color value is used to form the hashed key value. 0 Color register not used. 1 Color register is used

Table 8-17. LUDefTable Entry Definitions (Page 2 of 3)

Field	Bit Length	Description
P1P2_Max_Size	5	Maximum size of Pattern1 and Pattern2 in leaf - Indicates size in half words (that is, 16 bits) reserved for the “pattern” as a part of leaf in bytes. The maximum pattern size is 12, which represents 192 bits. P1P2_Max_size mapping: 00000 0 byte (no pattern) 00001 2 byte 00010 4 bytes 00011 6 bytes 00100 8 bytes 00101 10 bytes 00110 12 bytes 00111 14 bytes 01000 16 bytes 01001 18 bytes 01010 20 bytes 01011 22 bytes 01100 24 bytes Others 0 byte (Reserved) NOTE: For FM: Unused bits between p1p2_max_size - hkey_length must be initilized to zero. For LPM: Unused bits between (p1p2_max_size - prefix_length) do not have to be initialized and can be used by userdata since these bits do not take part in the comparsion. For SMT: Unused bit between (2 * p1p2_max_size - 2 * Hashedkey_length) must be initialized to zero.
NLARope_En	1	NLA Rope Enable control value. This field indicates whether or not the leaf contains a Next Leaf Address Rope (NLA Rope) field. 0 Leaf does not contain NLARope field 1 Leaf contains NLARope field (enables aging)
PSCB_FQ_Index	6	Pattern Search Control Block Free Queue Index value. This is the index of the PSCB free list.
PSCB_Height	1	Height (part of the Shape) of a PSCBEntry. Width of a PSCB is always 1. 0 Height = 1 (FM/SMT ZBT SRAM, FM/SMT H1 SRAM, FM/LPM/SMT DDR SDRAM) 1 Height = 2 (LPM ZBT SRAM, LPM H1 SRAM) In NP4GS3B (R2.0), this field is unused and does not affect operation.
DT_Base_Addr	26	Direct Table Base Address value.

Table 8-17. LUDefTable Entry Definitions (Page 3 of 3)

Field	Bit Length	Description
DT_Size	4	Direct Table Size value - defines the number of DT entries within a memory bank. 0001 4 entries, (2 bits) 0010 16 entries, (4 bits) 0011 64 entries, (6 bits) 0100 256 entries, (8 bits) 0101 1 K entries, (10 bits) 0110 4 K entries, (12 bits) 0111 16 K entries, (14 bits) 1000 64K entries (16 bits), NP4GS3A (R1.1); 32K entries (16 bits), NP4GS3B (R2.0) 1001 256K entries (18 bits), NP4GS3A (R1.1); 64K entries (14 bits), NP4GS3B (R2.0) 1010 1M entries (20 bits), NP4GS3A (R1.1); 128K entries (17 bits), NP4GS3B (R2.0) 1011 256K entries, (18 bits) NP4GS3B (R2.0) 1100 512 K entries, (19 bits) NP4GS3B (R2.0) 1101 1 M, (20 bits) NP4GS3B (R2.0) Others Reserved
Leaf_FQ_Index	6	Defines index of leaf free list
Leaf_Width	2	Leaf width
Leaf_Height	3	Leaf height
LUDef_State	2	LUDef state - used by Product Software/User Code to indicate current status of the entry. These bits do not affect Tree Search operation.
LUDef_Invalid	1	Indicates whether or not this entry is valid for normal Tree Search command or not. This bit blocks any tree search while the tree is being built or swapped. 0 Valid 1 Invalid When the LUDef Read request initiated by the Tree Search command finds this bit set to '1', it will re-read this LUDefEntry every 16 cycles until it is set to Valid. This halts the tree search for this particular thread.
Following fields are valid for GTH Only		
RopeCLA	26	Current leaf address for rope
RopePLA	26	Previous leaf address for rope
LeafCnt	26	Number of leaves in tree
LeafTh	10	Threshold for the number of leaves in a tree. If the LeafCnt is greater than or equal to this assigned threshold, then a class 0 interrupt is generated (bit 9 of the class 0 interrupt vector). For NP4GS3A (R1.1), whenever the LUDef Table Entry is read, checking of threshold is performed. This checking is not restricted to rope commands. Therefore, this checking happens for all the commands (e.g., tree search). For NP4GS3B (R2.0), checking of the threshold is performed only for the TLIR rope command. The threshold is formed by the generation of two 26-bit numbers that are bit-wise ORed resulting in a threshold value that is compared to the LeafCnt: threshold(25:0) = 2**(LeafTh(9:5))or 2**(LeafTh(4:0))

8.2.5.2 TSE Free Lists (TSE_FL)

The GTH has access to a set of 64 TSE free list control blocks, each defining a free list using the format shown in *Table 8-18*. Free lists typically chain unused PSCBs and leaves into a linked list, but can also be used by picocode to manage memory. The link pointer is stored in the control store at the address of the

previous list object. Objects stored in different memories and with different shapes should be placed in different free lists. For example, a list of 64-bit PSCBs stored in both ZBT SRAM and internal RAM should have different entries. The GTH thread executes the TSENQFL and TSDQFL commands to enqueue and dequeue addresses on a free list. See section *8.2.8.3 Tree Search Enqueue Free List (TSENQFL)* on page 338 and section *8.2.8.4 Tree Search Dequeue Free List (TSDQFL)* on page 338.

A free list of N objects, each with shape of width = W, height = H and a start address of "A", is created by enqueueing address A, A+H, A+2H, A+3H, … A+(N-1)H in the free list. To prevent memory bottlenecks, free lists can also be created in a "sprayed" manner for objects contained in SDRAM. For example, when searching a large LPM tree with five PSCBs in a single bank, the bank must be accessed five times before reaching a leaf. When the PSCBs are sprayed among multiple banks, the number of accesses remains identical but accesses are to multiple banks, thus eliminating bottlenecks.

Table 8-18. Free List Entry Definition

Field	Bit Length	Description
Head	26	Free list head address in the control store.
Tail	26	Free list tail address in the control store.
QCnt	26	Number of entries in the free list.
Threshold	5	Threshold value for the free list control block entry. This field is initialized to 0. The threshold is determined as 2**Threshold. When the QCnt is less than or equal to the threshold, a Class 0 interrupt (bit 8) is generated.

8.2.6 TSE Registers and Register Map

Table 8-19. TSE Scalar Registers for GTH Only (Page 1 of 2)

Name	Read/ Write	Hex Address	Bit Length	Description
Color	R/W	00	16	Color - see section *8.2.1 Input Key and Color Register for FM and LPM Trees* on page 304 and section *8.2.2 Input Key and Color Register for SMT Trees* on page 304.
LCBA0	R/W	02	26	Leaf Control Block Address 0 - typically contains the control store address of the leaf in TSR0, but is also used as an address register for various TSE commands.
LCBA1	R/W	03	26	Leaf Control Block Address 1 - typically contains the control store address of the leaf in TSR1, but is also used as an address register for various TSE commands.
DTA_Addr	R/W	04	26	DTEntry Address - valid after a hash has been performed.
DTA_Shape	R/W	05	5	Shape of a DTEntry - always (1,1) when direct leaves are disabled. Equals the leaf shape as defined in LUDefTable when direct leaves are enabled. Always set to '00000'.
HashedKeyLen	R/W	06	8	Pattern length minus 1 in HashedKey
CacheFlags	R	07	3	See section *8.2.3.3 Cascade/Cache* on page 306
NrPSCBs	R	08	8	See section *8.2.3.3 Cascade/Cache* on page 306
HashedKey	R/W	0A-0F	192	Contains HashedKey
HashedKey 191_160	R/W	0A	32	Bits 191..160 of HashedKey
HashedKey 159_128	R/W	0B	32	Bits 159..128 of HashedKey
HashedKey 127_96	R/W	0C	32	Bits 127..96 of HashedKey
HashedKey 95_64	R/W	0D	32	Bits 95..64 of HashedKey

Table 8-19. TSE Scalar Registers for GTH Only (Page 2 of 2)

Name	Read/ Write	Hex Address	Bit Length	Description
HashedKey 63_32	R/W	0E	32	Bits 63..32 of HashedKey
HashedKey 31_0	R/W	0F	32	Bits 31..0 of HashedKey
LUDefCopy	R	10-12	96	Contains LU_Def_Table index in use and a copy of the following LU_Def_Table fields: Field bits definition reserved 95:88 x'00'reserved LU_Def_Index 87:80 Index of the location from where the content was read. For remaining field definitions, see *Table 8-17: LUDefTable Entry Definitions* on page 312, with exceptions noted. LU_Def_Invalid 79 LU_Def_State 78:77 Reserved 76:75 reserved Leaf_Height 74:72 Leaf_Width 71:70 Leaf_FQ_Index 69:64 Reserved 63:62 reserved DT_Size 61:58 DT_Base_Addr 57:32 Reserved 31:23 PSCB_Height 22 PSCB_FQ_Index 21:16 Reserved 15:14 reserved NLA_Rope_Ena 13 P1P2_Max_Size 12:8 Color_Ena 7 Hash_Type 6:3 Search_Type 2:1 Cascade/Cache Entry 0
LUDefCopy 95_64	R	10	32	Bits 95:64 of the LUDefCopy register
LUDefCopy 63_32	R	11	32	Bits 63..32 of LUDefCopy
LUDefCopy 31_0	R	12	32	Bits 31..0 of LUDefCopy
SetPatbit_GDH	R/W	1B	1	Contains one bit from the pattern stored in TSRx. Set by SetPatBit_GDH command.
DistPosReg_GDH	R	1A	8	Contains result of DISTPOS command from DistPos_GDH
LUDefCopy_GDH	R	19	26	Contains LUDefTable index in use and a copy of the following LUDefTable fields: Reserved = LUDefCopy_GDH(25,24,23), Leaf_format_type = LUDefCopy_GDH(22,21), P1P2_max_size = LUDefCopy_GDH(20 to 16), DT_size= LUDefCopy_GDH(15 to 12), NLARope_en = LUDefCopy_GDH(11), color_en = LUDefCopy_GDH(10), Tree_Type = LUDefCopy_GDH(9,8), LuDefTable_index= LUDefCopy_GDH(7 to 0)
LUDefCopy_GDH 31_0	R	19	26	Bit 31..0 of LUDefCopy_GDH

Table 8-20. TSE Array Registers for All GxH

Name	Read/ Write	Starting Hex Address	Ending Hex Address	Bit Length	Description
TSR0	R/W	32	47	2048	Tree Search Result Area 0 Note: Portion of the data overlaps with TSR1
TSR1	R/W	40	47	1024	Tree Search Result Area 1 Note: Portion of the data overlaps with TSR0
TSR2	R/W	48	63	2048	Tree Search Result Area 2 Note: Portion of the data overlaps with TSR3
TSR3	R/W	56	63	1024	Tree Search Result Area 3 Note: Portion of the data overlaps with TSR2
Note: In this table, starting and ending Address represents the offset for a given thread's starting address in the Shared Memory Pool.					

Table 8-21. TSE Registers for GTH (Tree Management)

Name	Read/ Write	Hex Address	Bit Length	Description
PatBit_TSR0	R/W	1E	1	Contains one bit from the pattern stored in TSR0. Set by TRS0PAT command.
DistPosReg	R	1F	8	Contains result of DISTPOS command
LURopeCopyTH	R	13	10	Contains copy of LeafTH field of LUDefTable
LURopeCopyQCnt	R	14	26	Contains copy of LeafCnt field of LUDefTable
LURopeCopyPrev	R	15	26	Contains copy of RopePLA field of LUDefTable
LURopeCopyCurr	R	16	26	Contains copy of RopeCLA field of LUDefTable

Table 8-22. TSE Scalar Registers for GDH and GTH

Name	Read/ Write	Hex Address	Bit Length	Description
LCBA0	R/W	02	31	Leaf Control Block Address 0 - typically contains the control store address of the leaf in TSRx, but is also used as an address register for various TSE commands. Bits 30:26 The Leaf Control Block Address Shape which is used by CMPEND instruction only Bits 25:0 Leaf Control Block Address
LCBA1	R/W	03	31	Leaf Control Block Address 1 - typically contains the control store address of the leaf in TSRx, but is also used as an address register for various TSE commands. Bits 30:26 The Leaf Control Block Address Shape which is used by CMPEND instruction only Bits 25:0 Leaf Control Block Address
CacheFlags	R	07	3	See section *8.2.3.3 Cascade/Cache* on page 306
NrPSCBs	R	08	8	See section *8.2.3.3 Cascade/Cache* on page 306

Table 8-22. TSE Scalar Registers for GDH and GTH

Name	Read/ Write	Hex Address	Bit Length	Description
SetPatbit_GDH	R/W	1B	1	Contains one bit from the pattern stored in TSRx. Set by SetPatBit_GDH command
DistPosReg_GDH	R	1A	8	Contains result of DISTPOS command from DistPos_GDH
LUDefCopy_GDH	R	19	26	Contains LUDefTable index in use and a copy of the following LUDefTable fields: Reserved = LUDefCopy_GDH(25,24,23), Leaf_format_type = LUDefCopy_GDH(22,21), P1P2_max_size = LUDefCopy_GDH(20 to 16), DT_size= LUDefCopy_GDH(15 to 12), NLARope_en = LUDefCopy_GDH(11), color_en = LUDefCopy_GDH(10), Tree_Type = LUDefCopy_GDH(9,8), LuDefTable_index= LUDefCopy_GDH(7 to 0)

Table 8-23. PSCB Register Format

Field	Bit Length	Control Store Address for PSCB
NPA0	26	Next PSCB address - pointer to next PSCB in tree for PSCB part 0
NBT0	8	Next bit to test for PSCB part 0
LCBA0	26	Leaf control block address: Pointer to leaf for PSCB part 0
NPA1	26	Next PSCB address - Pointer to next PSCB in tree for PSCB part 1
NBT1	8	Next bit to test for PSCB part 1
LCBA1	26	Leaf control block address - Pointer to leaf for PSCB part 1
Index	8	Index of current PSCB physically stored in previous PSCB
PatBit	1	Value of HashedKey[Index] based on value of index field in PSCB register

Table 8-24. TSE GTH Indirect Registers

Indirect Register	Bit Length	Description	Notes
PSCBx.NPA_HK	26	Selects either the NPA0 field from PSCBx or the NPA1 field depending on value of register PSCBx.Index	1, 2, 3
PSCBx.NPA_TSR0	26	Selects either the NPA0 field from PSCBx or the NPA1 field depending on value of register PatBit_TSR0. (Register PatBit_TSR0 must have been initialized previously using TSR0PAT command)	1, 2, 4
PSCBx.NBT_HK	8	Selects either the NBT0 field from PSCBx or the NBT1 field depending on value of register PSCBx.Index	1, 2, 3
PSCBx.NBT_TSR0	8	Selects either the NBT0 field from PSCBx or the NBT1 field depending on value of register PatBit_TSR0	1, 2, 4
PSCBx.LCBA_HK	26	Selects either the LCBA0 field from PSCBx or the LCBA1 field depending on value of register PSCBx.Index	1, 2, 3
PSCBx.LCBA_TSR0	26	Selects either the LCBA0 field from PSCBx or the LCBA1 field, depending on value of register PatBit_TSR0	1, 2, 4
PSCBx.NotNPA_HK	26	Selects either the NPA0 field from PSCBx or the NPA1 field depending on inverse value of register PSCBx.Index	1, 2, 3
PSCBx.NotNPA_TSR0	26	Selects either the NPA0 field from PSCBx or the NPA1 field depending on inverse value of register PatBit_TSR0	1, 2, 4

Table 8-24. TSE GTH Indirect Registers (Continued)

Indirect Register	Bit Length	Description	Notes
PSCBx.NotNBT_HK	8	Selects either the NBT0 field from PSCBx or the NBT1 field depending on inverse value of register PSCBx.Index	1, 2, 3
PSCBx.NotNBT_TSR0	8	Selects either the NBT0 field from PSCBx or the NBT1 field depending on inverse value of register PatBit_TSR0	1, 2, 4
PSCBx.NotLCBA_HK	26	Selects either the LCBA0 field from PSCBx or the LCBA1 field depending on inverse value of register PSCBx.Index	1, 2, 3
PSCBx.NotLCBA_TSR0	26	Selects either the LCBA0 field from PSCBx or the LCBA1 field depending on inverse value of register PatBit_TSR0	1, 2, 4

1. x must equal 0, 1, or 2.
2. The Indirect registers of the TSE select, via dedicated hardware assist, one of the TSE registers listed in section *8.2.6 TSE Registers and Register Map* on page 315. The Indirect registers appear in the TSE Register Map with a unique register number.
3. PSCBx.Index points to a specific bit in the HashedKey. The bit's value determines whether the 0 or 1 part of PSCBx will be read or written.
4. Value of PatBit_TSR0 determines whether the 0 or 1 part of PSCBx will be read or written.

Table 8-25. Address Map for PSCB0-2 Registers in GTH

PSCBx	Read/Write	PSCB0	PSCB1	PSCB2	Size
NPA0	R/W	80	A0	C0	26

8.2.7 TSE Instructions

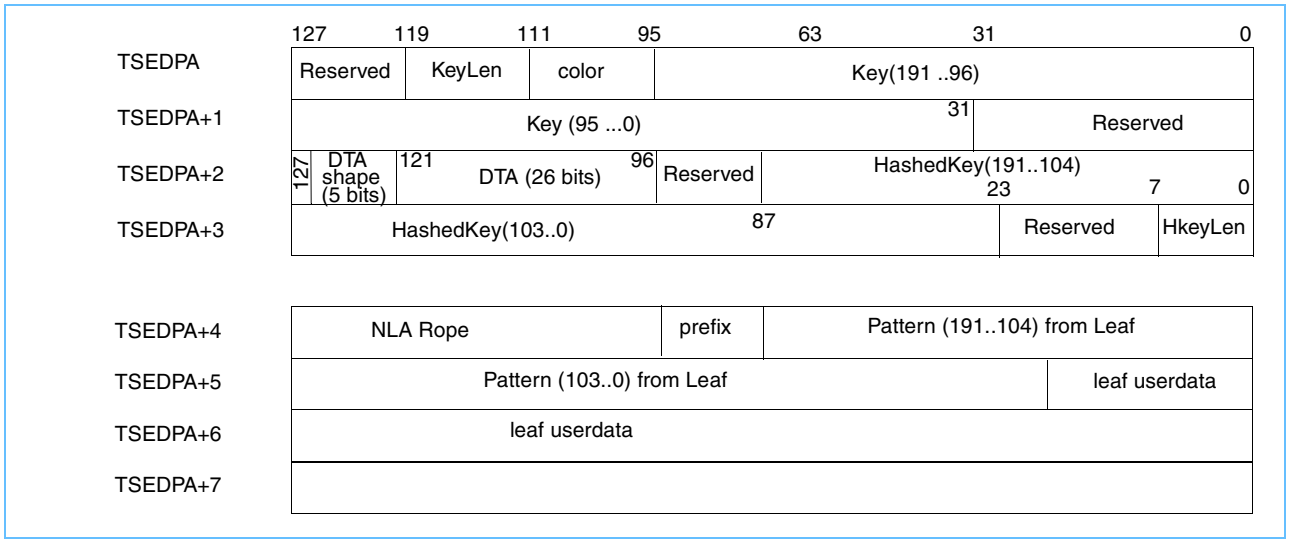
The Tree Search Engine (TSE) provides facilities for conducting and managing tree searches. Two TSE coprocessor interfaces are provided for each thread: TSE0 and TSE1. Therefore, each thread can issue instructions to each of these TSE0 and TSE1 resources.

Table 8-26. General TSE Instructions

Opcode	Command	Detail Section
0	Null	
1	TS_FM	*8.2.7.1 FM Tree Search (TS_FM)* on page 321
2	TS_LPM	*8.2.7.2 LPM Tree Search (TS_LPM)* on page 322
3	TS_SMT	*8.2.7.3 SMT Tree Search (TS_SMT)* on page 324
4	MRD	*8.2.7.4 Memory Read (MRD)* on page 325
5	MWR	*8.2.7.5 Memory Write (MWR)* on page 326
6	HK	*8.2.7.6 Hash Key (HK)* on page 327
7	RDLUDEF	*8.2.7.7 Read LUDefTable (RDLUDEF)* on page 328
8	COMPEND	*8.2.7.8 Compare-at-End (COMPEND)* on page 329
9	DistPos_GDH	*8.2.7.9 DistinguishPosition for Fast Table Update (DISTPOS_GDH)* on page 330
10	RDPSCB_GDH	*8.2.7.10 Read PSCB for Fast Table Update (RDPSCB_GDH)* on page 332
11	WRPSCB_GDH	*8.2.7.11 Write PSCB for Fast Table Update (WRPSCB_GDH)* on page 333
12	SetPatBit_GDH	*8.2.7.12 SetPatBit_GDH* on page 334
13 to15	Reserved	
Note: Commands can be executed by all GxHs with threads.		

Since two types of instruction set groupings differentiate GDH and GTH commands, the assembler uses *TSE0_* to indicate the GDH commands and *TSE1_* prefixes to indicate the GTH commands. On the GTH thread only one GTH command can be executed at a time, and a second *TSE* (GDH or GTH) command is not permitted.

Figure 8-5. General Layout of TSE Fields in Shared Memory Pool



8.2.7.1 FM Tree Search (TS_FM)

Table 8-27. FM Tree Search Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable that controls the search.
LCBANr	1	Imm16(0)	Imm12(0)	0 search results are stored in TSRx/LCBA0. 1 search results are stored in TSRx/LCBA1.
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address. Stores location of Key, Key-Length, and Color and determines Leaf destination. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', x'A', x'C', and x'E'.
Key	192	Shared Memory Pool		Key. Pattern to be searched, located in Shared Memory Pool. Must be initialized before search (NP4GS3A (R1.1) only). The key must be initialized only in the byte boundary of the key length (NP4GS3B (R2.0) only).
KeyLength	8	Shared Memory Pool		KeyLength. Length of pattern minus 1 in key. Must be initialized before search. Located in shared memory pool.
Color	16	Shared Memory Pool		Color. Used only when enabled in LUDefTable. Must be initialized before search. Located in Shared Memory Pool.
Following is available for GTH only.				
UseLUDefCopyReg	1	Imm16(13)	Imm12(5)	Enables TSE read of LUDefCopy register. Can save clock cycles, especially when RDLUDEF is executed asynchronously with the picocode that sets the key. 0 TSE reads LUDefTable. 1 TSE does not read the LUDefTable and uses information contained in LUDefCopy register. Assumes LUDefTable was read previously using RDLUDEF.
LUDefCopy	96	Register		Input only when UseLUDefCopyReg is '1'.

Table 8-28. FM Tree Search Results (TSR) Output

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 KO: Unsuccessful Operation. 1 OK: Successful Operation.
TSRx	512	Shared Memory Pool	When OK/KO is '1', leaf is read and stored in TSRx. TSRx is mapped into the Shared Memory pool, at an offset of 4 QW past the starting QW indicated by the input TSEDPA parameter. That is, the Shared Memory Pool QW location = TSEDPA*4 + 4
LCBA0 / 1	26	Register	When OK/KO is '1', leaf address is stored in LCBA0 / 1.
CacheFlags	3	Register	See section *8.2.3.3 Cascade/Cache* on page 306.
NrPSCBs	8	Register	See section *8.2.3.3 Cascade/Cache* on page 306.
LUDefCopy_GDH	26	Register	Contains LUDefTable index in use and a copy of the following LUDefTablefields: Reserved LUDefCopy_GDH(25,24,23) Leaf_format_type LUDefCopy_GDH(22,21) P1P2_max_size LUDefCopy_GDH(20 to 16) DT_size LUDefCopy_GDH(15 to 12) NLARope_en LUDefCopy_GDH(11) color_en LUDefCopy_GDH(10) Tree_Type LUDefCopy_GDH(9,8) LuDefTable_index LUDefCopy_GDH(7 to 0) Will be stored in scalar register and its address in Register Address Map is '019'.
Following is available for GTH only.			
LUDefCopy	96	Register	Output only when UseLUDefCopyReg is '0'. Set to contents of LUDefTable at entry pointed to by LUDefIndex.

8.2.7.2 LPM Tree Search (TS_LPM)

Table 8-29. LPM Tree Search Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable used to control the search
LCBANr	1	Imm16(0)	Imm12(0)	0 search results are stored in TSRx/LCBA0 1 search results are stored in TSRx/LCBA1
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address. Stores location of Key, Key-Length, and Color and determines Leaf destination. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', x'A', x'C', and x'E'.
Key	192	Shared Memory Pool		Key. Pattern to be searched, located in Shared Memory Pool. Must be initialized before search (NP4GS3A (R1.1) only). The key must be initialized only in the byte boundary of the key length (NP4GS3B (R2.0) only).
KeyLength	8	Shared Memory Pool		KeyLength - length of pattern minus 1 in key. Must be initialized before search. Located in shared memory pool.
Color	16	Shared Memory Pool		Color - used only when enabled in LUDefTable. Must be initialized before search. Located in Shared Memory Pool.

Table 8-29. LPM Tree Search Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
Following is available for GTH only.				
UseLUDefCopyReg	1	Imm16(13)	Imm12(5)	Enables TSE read of LUDefCopy register Can save clock cycles, especially when RDLUDEF is executed asynchronously with the picocode that sets the key. 0 TSE reads LUDefTable 1 TSE does not read the LUDefTable and uses information contained in LUDefCopy register. Assumes LUDefTable was read previously using RDLUDEF. Special Note: UseLUDefCopyReg = '1' is not supported for LUDefEntry with Cache_enable.
LUDefCopy	96	Register		Input only when UseLUDefCopyReg is '1'. Set to contents of LUDefTable at entry given by LUDefIndex.

Table 8-30. LPM Tree Search Results Output

Result	Bits	Source	Description
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation
TSRx	512	Shared Memory Pool	When OK/KO is '1', leaf is read and stored in TSRx TSRx is mapped into the Shared Memory pool, at an offset of 4 QW past the starting QW indicated by the input TSEDPA parameter. That is, Shared Memory Pool QW location = TSEDPA*4 + 4
LCBA0 / 1	26	Register	When OK/KO is '1', leaf address is stored in LCBA0 / 1
CacheFlags	3	Register	See section *8.2.3.3 Cascade/Cache* on page 306
NrPSCBs	8	Register	See section *8.2.3.3 Cascade/Cache* on page 306
LUDefCopy_GDH	26	Register	Contains LUDefTable index in use and a copy of the following LUDefTablefields: ReservedLUDefCopy_GDH(25,24,23) Leaf_format_typeLUDefCopy_GDH(22,21) P1P2_max_sizeLUDefCopy_GDH(20 to 16) DT_size LUDefCopy_GDH(15 to 12) NLARope_enLUDefCopy_GDH(11) color_enLUDefCopy_GDH(10) Tree_TypeLUDefCopy_GDH(9,8) LuDefTable_indexLUDefCopy_GDH(7 to 0) Will be stored in scalar register, and its address in Register Address Map is '019'.
The following is available for GTH only.			
LUDefCopy	96	Register	Output only when UseLUDefCopyReg is '0'. Set to contents of LUDefTable at entry given by LUDefIndex.

8.2.7.3 SMT Tree Search (TS_SMT)

Table 8-31. SMT Tree Search Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable used to control the search
LCBANr	1	Imm16(0)	Imm12(0)	0 search results are stored in TSRx/LCBA0 1 search results are stored in TSRx/LCBA1
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address - stores location of Key, KeyLength, and Color and determines Leaf destination. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', x'A', x'C', and x'E'.
Key	192	Shared Memory Pool		Key. Pattern to be searched, located in shared memory pool. Must be initialized before search (NP4GS3A (R1.1) only). The key must be initialized only in the byte boundary of the key length (NP4GS3B (R2.0) only).
KeyLength	8	Shared Memory Pool		KeyLength. Length of pattern minus 1 in key. Must be initialized before search. Located in shared memory pool.
Color	16	Shared Memory Pool		Color. Used only when enabled in LUDefTable. Must be initialized before search. Located in shared memory pool.
Following is available for GTH only.				
UseLUDefCopyReg	1	Imm16(13)	Imm12(5)	Enables TSE read of LUDefCopy register Can save clock cycles, especially when RDLUDEF is executed asynchronously with the picocode that sets the key. 0 TSE reads LUDefTable 1 TSE does not read the LUDefTable and uses information contained in LUDefCopy register. Assumes LUDefTable was read previously using RDLUDEF. Special Note: UseLUDefCopyReg = '1' is not supported for LUDefEntry with Cache Enable.
LUDefCopy	96	Register		Input only when UseLUDefCopyReg is '1'. Set to contents of LUDefTable at entry given by LUDefIndex.

Table 8-32. SMT Tree Search Results Output

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation
TSRx	512	Shared Memory Pool	When OK is '1', leaf is read and stored in TSRx. TSRx is mapped into the Shared Memory pool, at an offset of 4 QW past the starting QW indicated by the input TSEDPA parameter. That is, Shared Memory Pool QW location = TSEDPA*4 + 4
LCBA0 / 1	26	Register	When OK is '1', leaf address is stored in LCBA0 / 1
CacheFlags	3	Register	See section *8.2.3.3 Cascade/Cache* on page 306
NrPSCBs	8	Register	See section *8.2.3.3 Cascade/Cache* on page 306

Table 8-32. SMT Tree Search Results Output

Result	Bit Length	Source	Description
LUDefCopy_GDH	26	Register	Contains LUDefTable index in use and a copy of the following LUDefTablefields: Reserved = LUDefCopy_GDH(25,24,23), Leaf_format_type = LUDefCopy_GDH(22,21), P1P2_max_size = LUDefCopy_GDH(20 to 16), DT_size = LUDefCopy_GDH(15 to 12), NLARope_en = LUDefCopy_GDH(11), color_en = LUDefCopy_GDH(10), Tree_Type = LUDefCopy_GDH(9,8), LuDefTable_index = LUDefCopy_GDH(7 to 0) Will be stored in scalar register, and its address in Register Address Map is '019'.
Following are available for GTH only.			
LUDefCopy	96	Register	An output only when UseLUDefCopyReg is '0'. Set to contents of LUDefTable at entry given by LUDefIndex.

8.2.7.4 Memory Read (MRD)

The memory read command provides direct read capability from any location in the control store. LCBA0 / 1 provide the full read address. Shape is provided by the LUDefTable (for Leaf or PSCB) or directly as part of the command field for the object. The content to be read is stored in TSRx.

Table 8-33. Memory Read Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
ShapeCtrl	2	Imm16(14..13)	GPR(9..8)	00 Direct shape 10 PSCB shape is based on address and tree type from LudefTable. That is, LPM tree type and ZBT or H1 address shape will be set to (1x2), and for any other case, shape will be set to (1x1). 11 Leaf shape from LUDefTable
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	LUDefTable entry used to read shape information. Valid only when ShapeCtrl is '10' or '11'.
Width	2	Imm16(9..8)	GPR(4..3)	Width of object to be read. Valid only when ShapeCtrl is '00'.
Height	3	Imm16(7..5)	GPR(2..0)	Height of object to be read. Valid only when ShapeCtrl is '00'.
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address determines the destination location for the data to be read. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary.
LCBANr	1	Imm16(0)	Imm12(0)	0 Address to be read is LCBA0 1 Address to be read is LCBA1
LCBA0 / 1	26	Register		Address to be read

Table 8-34. Memory Read Output Results

Result	Bit Length	Source	Description
TSRx	512	Shared Memory Pool	TSRx is mapped into the Shared Memory pool, starting at the QW indicated by the input TSEDPA parameter for a length of 4 QW.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.7.5 Memory Write (MWR)

The memory write command provides direct write capability to any location in the control store. LCBA0 / 1 provide the full write address. Shape is provided by the LUDefTable (for Leaf or PSCB) or directly as part of the command field for the object. The content to be written is stored in TSRx.

Table 8-35. Memory Write Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
ShapeCtrl	2	Imm16(14..13)	GPR(9..8)	00 Direct Shape 10 PSCB shape is based on address and tree type from LudefTable. That is, LPM tree type and ZBT or H1 address shape will be set to (1x2), and for any other case, shape will be set to (1x1). 11 Leaf shape from LUDefTable
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	LUDefTable entry used to read shape information. Valid only when ShapeCtrl is ‘10’ or ‘11’.
Width	2	Imm16(9..8)	GPR(4..3)	Width of object to be read. Valid only when ShapeCtrl is ‘00’.
Height	3	Imm16(7..5)	GPR(2..0)	Height of object to be read. Valid only when ShapeCtrl is ‘00’.
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address determines the source location for the data to be written. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary.
LCBANr	1	Imm16(0)	Imm12(0)	0 Address to be written is LCBA0 1 Address to be written is LCBA1
LCBA0 / 1	26	Register		Address to be written
TSRx	512	Shared Memory Pool		Data to be written. TSRx is mapped into the Shared Memory pool, starting at the QW indicated by the input TSEDPA parameter for a length of 4 QW.

8.2.7.6 Hash Key (HK)

Table 8-36. Hash Key Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable containing Hash Type
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address - stores location of Key, Key-Length, and Color and determines Hash Key destination. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', x'A', x'C', and x'E'.
Direct_ HashType_En	1	Imm16(0)	Imm12(0)	Enable Direct HashType definition 0 HashType defined by LUDefEntry 1 HashType defined via command
Direct_ HashType	4	Imm16(8..5)	GPR(3..0)	Use defined Hash Type for Hashing. Valid when Direct_HashType_En = 1
Key	192	Shared Memory Pool		Key - pattern to be searched, located in Shared Memory Pool. Must be initialized before search (NP4GS3A (R1.1) only). The key must be initialized only in the byte boundary of the key length NP4GS3B (R2.0) only).
KeyLen	8	Shared Memory Pool		Defines length of pattern minus 1 in key. Must be initialized before search. Located in the Shared Memory Pool.
Color	16	Shared Memory Pool		Must be initialized before search - used only when enabled in LUDefTable. Located in the shared memory pool. Invalid when Direct_HashType_En is set to value '1'.

Table 8-37. Hash Key Output Results (Page 1 of 2)

Result	Bit Length	Source	Description
HashedKeyReg	192	Shared Memory Pool	Hashed key register - contains the HashedKey (including color when enabled in LUDefTable) according to section *8.2.1 Input Key and Color Register for FM and LPM Trees* on page 304 and section *8.2.2 Input Key and Color Register for SMT Trees* on page 304. Hash function is defined in the LUDefTable. Stored in the Shared Memory Pool QW location = TSEDPA*4 + 2 & 3.
HashedKeyLen	8	Shared Memory Pool	Hashed key length contains the length of pattern minus 1 in HashedKeyReg. Stored in the shared memory pool QW location = TSEDPA*4 + 3 bit (7:0).
DTA	26	Shared Memory Pool	DTEntry Address. Stored in shared memory pool QW location = TSEDPA*4 + 2, bits (121:96). **Note:** Not valid when Direct_HashType_En is set to value '1'.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

Table 8-37. Hash Key Output Results (Page 2 of 2)

Result	Bit Length	Source	Description
LUDefCopy_GDH	26	Register	Contains LUDefTable index in use and a copy of the following LUDefTablefields: Reserved = LUDefCopy_GDH(25,24,23), Leaf_format_type = LUDefCopy_GDH(22,21), P1P2_max_size = LUDefCopy_GDH(20 to 16), DT_size = LUDefCopy_GDH(15 to 12), NLARope_en = LUDefCopy_GDH(11), color_en = LUDefCopy_GDH(10), Tree_Type = LUDefCopy_GDH(9,8), LuDefTable_index = LUDefCopy_GDH(7 to 0) Will be stored in scalar register, and its address in Register Address Map is '019'.
The following is available for GTH only.			
LUDefCopy	96	Register	Set to contents of LUDefTable at entry given by LUDefIndex.

8.2.7.7 Read LUDefTable (RDLUDEF)

RDLUDEF reads LUDefTable at a specified entry and stores the result in the LUDefCopy register field in the shared memory pool.The TSE can read LUDefTable while picocode builds a key because RDLUDEF is executed asynchronously.

Figure 8-6. General Layout of TSE RDLUDEF in Shared Memory Pool

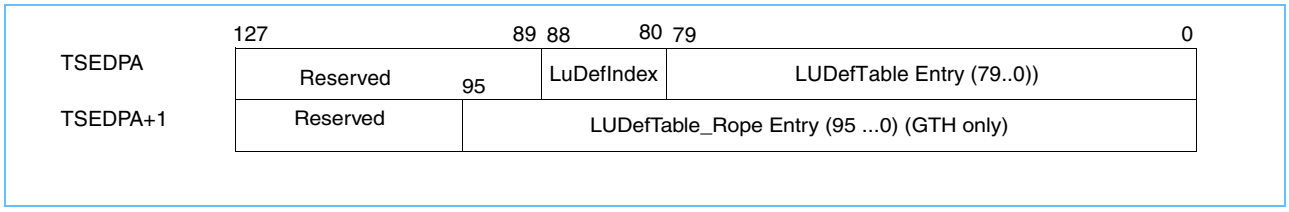


Table 8-38. RDLUDEF Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address determines the destination location for the LUDefTable entry data to be read. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary.

Table 8-39. RDLUDEF Output Results

Result	Bit Length	Source	Description
LUDefCopy	88	Shared Memory Pool	Set to contents of LUDefTable at entry given by LUDefIndex and stored in shared memory pool. The entry is placed into two QW starting at the QW indicated by the TSEDPA. The entry is right-justified with the most significant bits padded with 0. Various fields of LUDefEntry are at the same bit position as in the LUDefTable memory. (79 to 0) bits represent the LUDefEntry contents and bits (86 to 80) represents the corresponding LUDefIndex. They are right-justified. **Note:** TSEDPA address and TSEDPA + 1 will be overwritten during this command. Contents of LUDefCopy will be returned at TSEDPA and contents of LUDefCopy_Rope will be returned in the next address. LUDefCopy_Rope content will be valid for the GTH thread.
LUDefCopy_GDH	26	Register	Contains LUDefTable index in use and a copy of the following LUDefTablefields: Reserved = LUDefCopy_GDH(25,24,23), Leaf_format_type = LUDefCopy_GDH(22,21), P1P2_max_size = LUDefCopy_GDH(20 to 16), DT_size = LUDefCopy_GDH(15 to 12), NLARope_en = LUDefCopy_GDH(11), color_en = LUDefCopy_GDH(10), Tree_Type = LUDefCopy_GDH(9,8), LuDefTable_index = LUDefCopy_GDH(7 to 0) Will be stored in scalar register and its address in Register Address Map is ‘019’.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.7.8 Compare-at-End (COMPEND)

COMPEND performs a compare-at-end operation for SMT trees. After a tree search command has performed a full search including a COMPEND, picocode can obtain a pointer to another leaf chain from the leaf and start another COMPEND on the leaf chain. The first leaf chain could contain leaves with filtering information, and the second could contain leaves with quality of service information. COMPEND should be used only after a tree search command. The COMPEND command uses Key instead of HashedKey during operation, since it is assumed that hashing is not needed for SMT. Hence, the Key field is read by the command, not the HashedKey field. Also, since hashing is not done on the Key and it is used “as is,” it is necessary to initialize the unused key bits to zero.

Table 8-40. COMPEND Input Operands (Page 1 of 2)

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12:5)	GPR(7:0)	Defines the entry in the LuDefTable.
LCBNANr	1	Imm16(0)	Imm12(0)	0 Search results are stored in TSRx/LCBA0 1 Search results are stored in TSRx/LCBA1
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	TSE Thread Shared Memory Pool Address - stores location of Key, KeyLength, and Color and determines Leaf destination. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x’8’, x’A’, x’C’, and x’E’.

Table 8-40. COMPEND Input Operands (Page 2 of 2)

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LCBA0 / 1	31	Register		Start address of leaf chain and its shape. Bits: 30:29 Leaf Width 28:26 Leaf Height 25:0 Leaf Address **Note:** A Valid Leaf Width and Leaf Height must be provided with the Leaf Address.
Key	192	Shared Memory Pool		Input of previous tree search command located in the Shared Memory Pool at an offset of 0 and 1QW from the QW indicated by the TSEDPA.
KeyLen	8	Shared Memory Pool		Input of previous tree search command located in the Shared Memory Pool at the QW indicated by the TSEDPA

Table 8-41. COMPEND Output Results

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation
TSRx	512	Shared Memory Pool	When OK is '1', leaf is read and stored in TSRx When OK is '0', last leaf of chain is stored in TSRx TSRx is mapped into the Shared Memory pool, starting at an offset of 4 QW past the QW indicated by the input TSEDPA parameter for a length of 4 QW.
LCBA0 / 1	26	Register	When OK is '1', leaf address is stored in LCBA0 / 1 When OK is '0', leaf address of last leaf in chain is stored in LCBA0 / 1 **Note:** Shape for the corresponding leaf will not be valid when LCABA0/1 is read.

8.2.7.9 DistinguishPosition for Fast Table Update (DISTPOS_GDH)

DISTPOS_GDH performs a pattern compare between the pattern stored in HashedKey of the shared memory pool and a pattern from the leaf specified in TSRx. The result is stored in the DistPosReg_GDH register. The OK flag is set when a full match has been detected.

Figure 8-7. Shared Memory Pool with DISTPOS_GDH Command Subfields

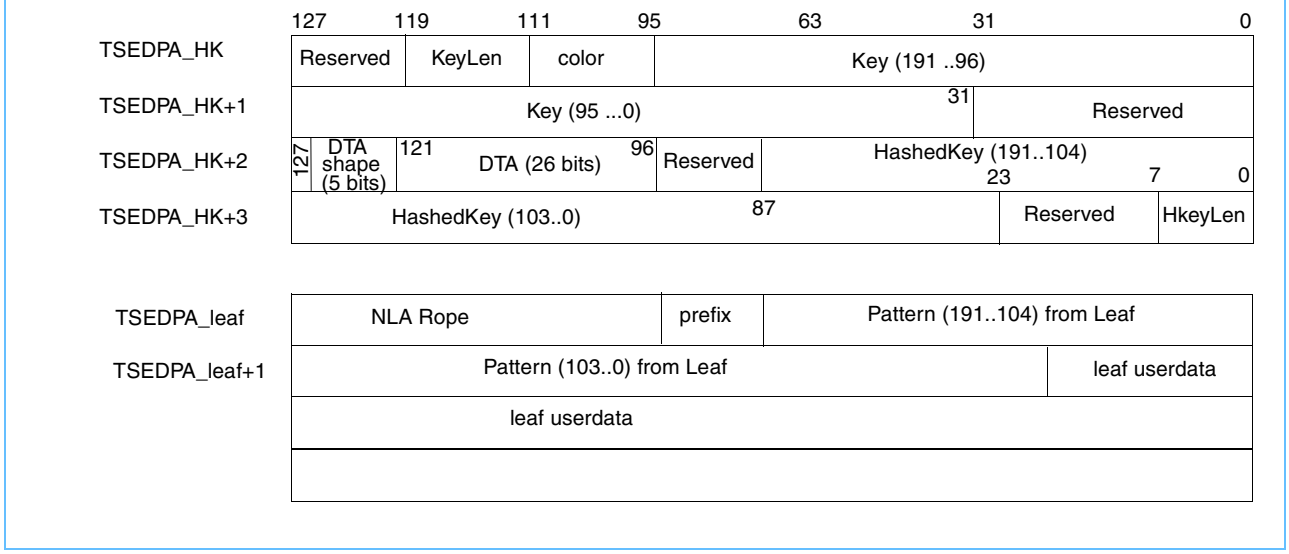

Table 8-42. DISTPOS_GDH Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
TSEDPA_leaf	4	Imm16(4..1)	Imm12(4..1)	Indicates the leaf storage location in the Thread Shared Memory Pool. The TSEDPA_leaf is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x '8', x 'A', x 'C', and x 'E'.
TSEDPA_HK	4	Imm16(8..5)	Imm12(8..5)	Indicates the HashedKey storage location in the Thread Shared Memory Pool. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see 7.2.10 Shared Memory Pool) and is constrained to be on a four-QW boundary. Use only values of x '8', x 'A', x 'C', and x 'E'. Hashedkey is assumed to be stored at TSEDPA +2 location in shared memory pool.
HashedKey	192	Shared Memory Pool		Contains the hashed pattern and it will be stored at TSEDPA_HK +2 (7..0) quad word location. The structure of the Hashed Key in shared memory pool is shown in *Figure 8-7*.
HashedKeyLen	8	Shared Memory Pool		Contains length of hashed pattern minus 1. Stored at TSEDPA_HK +2 quad word location. Structure of Hashed Key in shared memory pool is shown in *Figure 8-7*.
TSRx	512	Shared Memory Pool		Contains second pattern with pattern length (for LPM & FM only). TSRx is mapped into the shared memory pool, starting at an offset of 4 QW past the QW indicated by the input TSEDPA_leaf parameter for a length of 4 QW.

Table 8-43. DISTPOS_GDH Output Results

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 Pattern does not match 1 Pattern in HashedKey matches pattern in TSRx
DistPosReg_GDH	8	Scalar register	Smallest bit position where pattern in HashedKey differs from pattern in TSRx. Will be stored in scalar register and its address in the Register Address Map is '01A'.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

DISTPOS_GDH applies to LPM and FM only. It needs P1P2_Max_Size value as a part of the computation. The value is assumed to be valid prior to this command. This value is stored as a scalar register, and is independent for each thread.

8.2.7.10 Read PSCB for Fast Table Update (RDPSCB_GDH)

RDPSCB_GDH reads a PSCB from the control store and stores it in one of the PSCBx locations in the shared memory pool. For LPM, the entire PSCB is read from memory at the address given by PSCB.Addr and stored in PSCB. For FM, the entire PSCB is read from memory and converted into a LPM PSCB format and either NPA0/1 or LCBA0/1 will be set to all zero, since only one of the fields will be valid. This command is not supported for SMT.

Structure for PSCB register shared memory pool is as follows:

Figure 8-8. Shared Memory Pool with PSCB subfields

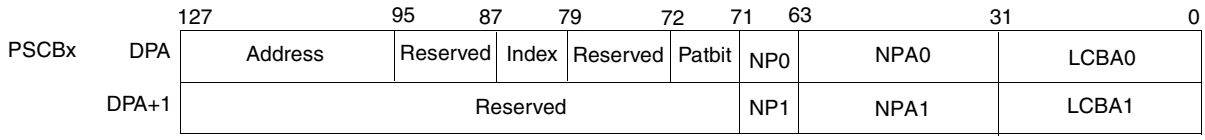

Table 8-44. RDPSCB_GDH Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
DPA_PSCB	6	Imm16(5..0)	Imm12(5..0)	The DPA_PSCB is a Full address of the *7.2.4 Shared Memory Pool* on page 193. This indicates working address of the PSCB register. Full PSCB will occupy 2 quadwords from shared memory pool. This address must start at an even address.
RdWrPSCB_Cntl	2	Imm16(7..6)	Imm12(7..6)	00 Result is based on PatBit value in the shared memory pool as shown in above diagram. PatBit = 0 Branch 0 entry of the PSCB is read PatBit = 1 Branch 1 entry of the PSCB is read 01 Branch 0 entry of the PSCB is read 10 Branch 1 entry of the PSCB is read 11 Branch 0 and branch 1 entry of the PSCB is read
RdWrPSC_DT_Flag	1	Imm16(8)	Imm12(8)	Indicates entry is DT. Note: Not valid for NP4GS3B (R2.0).
PSCB.Addr	26	shared memory pool (121..96)		Address to be written in control store of the PSCB. This is stored in shared memory pool.

Table 8-45. RDPSCB_GDH Output Results

Result	Bit Length	Source	Description
PSCB	- -	Register	PSCB is read from control store and stored in register PSCB<pn>. NPA0, NBT0, LCBA0 and NPA1, NBT1, LCBA1 fields are changed. Remainders are not changed. For FM: Content of either NPA0 or LCBA0 and NPA1 or LCBA1 will be set to zero i.e either NPA and LCBA will be valid. Also content of NBT0 will be set to zero when NPA0 is zero and NBT1 will be set to zero when NPA1 is zero. i.e for end node NBT and NPA is not valid. For SMT: Content of NPA0/1, NBT0/1 and LCBA0/1 will be based on the actual conten read from the memory. Logic will not zero out any part of the data.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.7.11 Write PSCB for Fast Table Update (WRPSCB_GDH)

WRPSCB_GDH writes a PSCB stored in PSCBx (in shared memory pool) to the control store. For LPM, the entire PSCB is written to memory to the address given by PSCB.Addr. For FM, the PSCB is written to memory in FMPSCB format. In both cases, WRPSCB_GDH generates the PSCB's two format bits. When the PSCB represents a DTEntry, only half of PSCB is written to memory. That is, the entire DTEntry is written by picocode. This command is not supported for SMT. pscb_cntl/format bits (which defines end node or valid presence of leaf) for the DT/PSCB entry will be computed based on the content of PSCB.LCBA0/1 and no checking/validation is performed, based on the PSCB.NPA0/1 or PSCB.NBT0/1, therefore PSCB.NBT0/1 will be written to memory as is and for LPM PSCB.NPA0/1 is written as is.

Table 8-46. WRPSCB_GDH Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
DPA_PSCB	6	Imm16(5..0)	Imm12(5..0)	The DPA_PSCB is a Full address of the *7.2.4 Shared Memory Pool* on page 193. This indicates that the working address of the PSCB register Full PSCB will occupy 2 quadwords from the shared memory pool. This address must start at an even address.
RdWrPSCB_Cntl	2	Imm16(7..6)	Imm12(7..6)	00 Action is based on PatBit value. PatBit = 0 Branch 0 entry of the PSCB is read PatBit = 1 Branch 1 entry of the PSCB is read 01 Branch 0 entry of the PSCB is read 10 Branch 1 entry of the PSCB is read 11 Branch 0 and branch 1 entry of the PSCB is read
RdWrPSC_DT_Flag	1	Imm16(8)	Imm12(8)	Indicates entry is DT. Note: Not valid for NP4GS3B (R2.0).
PSCB.Addr	26	shared memory pool (121..96)		Address to be written in control store of the PSCB. This is stored in shared memory pool.

Table 8-47. WRPSCB_GDH Output Results

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.7.12 SetPatBit_GDH

SetPatBit_GDH instruction reads a bit from the HashedKey pattern or Leaf Reference pattern stored in TSRx of the shared memory pool and stores this bit in the SetPatBit_GDH register. Picocode must copy it to the appropriate patbit field of TSEDPA_PSCBx of the shared memory pool.

Table 8-48. SetPatBit_GDH Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
DPA_PSCB	6	Imm16(5..0)	Imm12(5..0)	The DPA_PSCB is a Full address of the thread's shared address (see *7.2.4 Shared Memory Pool* on page 193). This indicates the working address of the PSCB register. The DPA_PSCBx.index field will be used.
TSEDPA_HK_leaf	4	Imm16(9..6)	Imm12(9..6)	Indicates the leaf or HashedKey storage location in the Thread Shared Memory pool. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x '8', x 'A', x 'C',and x 'E'. When HK_Leaf_flag = 0, HashedKey will be used for this operation. When HK_Leaf_flag = 1, Leaf content will be used for operation. When Leaf is to be used, Location for leaf will be TSEDPA_HK_leaf; and when HashedKey is used, Location for HashedKey will be TSEDPA_HK_leaf +2.
HK_leaf_flag	1	Imm16(10)	Imm12(10)	When HK_Leaf_flag = 0, HashedKey will be used for this operation and TSEDPA_HK_leaf +2 will be used as a HashedKey Location in shared memory pool. When HK_Leaf_flag = 1, Leaf content will be used for operation and TSEDPA_HK_leaf will be used as a Leaf location in shared memory pool.
HashedKey	192	Shared Memory Pool		Contains the hashed pattern, and it will be stored at TSEDPA_HK_leaf +2 & +3 QW location. Structure of Hashed Key in shared memory pool is shown in the above figure.
HashedKeyLen	8	Shared Memory Pool		Contains length of hashed pattern minus 1, and it will be stored at TSEDPA_HK_leaf +3 (7..0) QW location. Structure of Hashed Key in shared memory pool is shown in the above figure.
TSRx	512	Shared Memory Pool		Contains second pattern with pattern length (for LPM only). TSRx is mapped into the Shared Memory pool, starting at an offset of 4 QW past the QW indicated by the input TSEDPA_HK_leaf parameter, for a length of 4 QW.

Table 8-49. SetPatBit_GDH Output Results

Result	Bit Length	Source	Description
SetPatBit_GDH	1	Register	Smallest bit position where pattern in HashedKey differs from pattern in leaf at TSEDPA_HK_leaf location. Its address in register address map is "01B".
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

SetPatBit_GDH applies to LPM only, and requires the P1P2_Max_Size value as a part of its computation. This value is assumed to be valid prior to this command. The value is stored as a scalar register, and is independent for each thread.

8.2.8 GTH Hardware Assist Instructions

Note: GTH hardware assist instructions will not be supported in the future.

Table 8-50. General GTH Instructions

Opcode	Command	Detail Section

8.2.8.1 Hash Key GTH (HK_GTH)

Table 8-51. Hash Key GTH Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable containing hash type
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary.
Direct_ HashType_En	1	Imm16(0)	Imm12(0)	Enable Direct HashType definition 0 HashType defined by LUDefEntry 1 HashType defined via command
Direct_ HashType	4	Imm16(8..5)	GPR(3..0)	Use defined Hash Type for Hashing. Valid when DIrect_HashType_En = 1

Table 8-51. Hash Key GTH Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
Key	192	Shared Memory Pool		Provides pattern to be searched. Must be initialized before search. Located in the Shared Memory Pool.
KeyLen	8	Shared Memory Pool		Defines length of pattern minus 1 in key. Must be initialized before search. Located in the Shared Memory Pool.
Color	16	Shared Memory Pool		Must be initialized before search - used only when enabled in LUDefTable. Located in the Shared Memory Pool. Invalid when Direct_HashType_En is set to value '1'.

Table 8-52. Hash Key GTH Output Results

Result	Bit Length	Source	Description
HashedKeyReg	192	Register	Contains the HashedKey, including color when color is enabled in LUDefTable, according to section *8.2.1 Input Key and Color Register for FM and LPM Trees* on page 304 and section *8.2.2 Input Key and Color Register for SMT Trees* on page 304. Hash function is defined in LUDefTable. Hashed Key is NOT stored in Shared Memory Pool.
HashedKeyLen	8	Register	Contains length of pattern minus 1 in HashedKeyReg. Hashed Key is NOT stored in Shared Memory Pool.
DTA	26	Register	DTEntry Address (Hashed Key is NOT stored in Shared Memory Pool.)
LUDefCopy	96	Register	Set to contents of LUDefTable at entry given by LUDefIndex. Note: Valid for GTH Only.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.2 Read LUDefTable GTH (RDLUDEF GTH)

RDLUDEF reads the LUDefTable at a specified entry and stores the result in the LUDefCopy register. The TSE can read LUDefTable while picocode builds a key because *RDLUDEF* is executed asynchronously. Once the key is ready, the tree search execution can be executed with the UseLUDefCopyReg flag set to '1'.

Table 8-53. RDLUDEF_GTH Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable

Table 8-54. RDLUDEF_GTH Output Results

Result	Bit Length	Source	Description
LUDefCopy	96	Register	Scalar register contains content of LUDefTable at the entry. No content will be written back to Shared Memory Pool.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.3 Tree Search Enqueue Free List (TSENQFL)

TSENQFL releases a control block such as a leaf or PSCB to a free list. The address of the memory location to be freed is stored in LCBA0 / 1. The leaf or PSCB index to the free list is provided by the LUDefTable or directly by the command line. The enqueue operation always adds an address to the bottom of a free list FIFO-style. Entries cannot be added or removed from the middle of a free list. When FreeListCtrl = 11, TSENQFL increments the LeafCount field in LUDefTable.

Table 8-55. TSENQFL Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
FreeListCtrl	2	Imm16(14..13)	GPR(9..8)	00 Direct Free List Index 10 PSCB Free List Index from LUDefTable 11 Leaf Free List Index from LUDefTable
LUDefIndex/ FreeListIndex	8	Imm16(12..5)	GPR(7..0)	Defines the entry in the LUDefTable used to read free list index information or directly defines FreeListIndex.
SrcType	3	Imm16(2..0)	Imm12(2..0)	000 LCBA0 001 LCBA1 100 PSCB0.Addr (for GCH only) 101 PSCB1.Addr (for GCH only) 110 PSCB2.Addr (for GCH only)
LCBA0 / 1 PSCB0 / 1 / 2.Addr	26	Register		The address to be freed or enqueued

Table 8-56. TSENQFL Output Results

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.4 Tree Search Dequeue Free List (TSDQFL)

TSDQFL dequeues an address from a given FQlinklist. The address that has been dequeued from the free list is stored in LCBA0 / 1. The leaf or PSCB index to the free list is provided by the LUDefTable or directly by the command line. When FreeListCtrl is '11', TSDQFL decrements the LeafCount field in LUDefTable.

Table 8-57. TSDQFL Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
FreeListCtrl	2	Imm16(14..13)	GPR(9..8)	00 Direct free list index 10 PSCB free list index from LUDefTable 11 Leaf free list index from LUDefTable
LUDefIndex/ FreeListIndex	8	Imm16(12..5)	GPR(7..0)	Defines the entry in LUDefTable used to read free list index information or directly defines FreeListIndex.
TgtType	3	Imm16(2..0)	Imm12(2..0)	000 LCBA0 001 LCBA1 100 PSCB0.Addr (for GCH only) 101 PSCB1.Addr (for GCH only) 110 PSCB2.Addr (for GCH only)

Table 8-58. TSDQFL Output Results

Result	Bit Length	Source	Description
LCBAO/1 PSCB0 / 1 / 2.Addr	26	Register	Dequeued address
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.5 Read Current Leaf from Rope (RCLR)

RCLR is used to “walk the rope” for such processes as aging. RCLR reads the leaf at the current leaf address defined in LUDefTable. It stores the leaf address in LCBA0 and the leaf contents in TSR0. When rope walking begins, the TSE invokes RCLR and picocode saves the leaf address (LCBA0) in a GPR. Before reading the next leaf, the TSE invokes the advance rope with optional delete leaf command (ARDL), after which RCLR can be invoked again. To determine whether a rope walk has ended, picocode compares LCBA0 with the GPR to verify whether the leaf that was read is the same as the first leaf. If the leaf is the same, the rope walk has ended.

At any time during the rope walk, picocode can delete a leaf from the rope using ARDL with the DeleteLeaf flag set to 1. This is useful when the leaf is to be aged out. RCLR can automatically delete leaves from the rope when the DeletePending bit in the leaf is set. When this feature is enabled, the TSE deletes a leaf and reads the next leaf, which is also deleted when the DeletePending bit is set. The process is repeated to delete multiple leaves.

After RCLR has executed with OK = 1, the contents of TSR0 and LCBA0 correspond with CLA in the LUDefTable, and the previous leaf on the rope has an address of PLA. OK = 0, or KO, means the rope is empty.

Table 8-59. RCLR Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable used to read rope
Reserved	3	Imm16(3..1)	Imm12(3..1)	Must be set to ‘000’
DelEnable	1	Imm16(0)	Imm12(0)	When ‘1’, leaves with DeletePending bit are automatically deleted from rope and leaf address will be enqueued in leaf free queue
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	Location for the leaf to be stored. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary.

Table 8-60. RCLR Output Results

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation
LCBA0	26	Register	Address of leaf that has been read
TSRx	512	Shared Memory Pool	Leaf content is stored in TSRx. TSRx is mapped into the Shared Memory pool, starting at an offset of 4 QW past the QW indicated by the input TSEDPA parameter for a length of 4 QW.

8.2.8.6 Advance Rope with Optional Delete Leaf (ARDL)

ARDL advances the rope, or updates CLA and PLA in LUDefTable. The NLA field from the leaf already stored in TSR0 is read and stored in CLA. PLA is then updated to the previous value of CLA unless the leaf is deleted. In this case, PLA remains the same and the NLARope field for the leaf with the current PLA address is set to the new CLA. When leaf deletion is enabled, the current leaf is deleted prior to advancing the rope. The contents of TSR0 and LCBA0 can be destroyed because ARDL uses TSR0 and LCBA0 as work areas to update the NLARope field. After ARDL is executed, CLA and PLA (in the LUDefTable) are updated and RCLR (described in the next section) can be executed again.

Table 8-61. ARDL Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable
DeleteLeaf	1	Imm16(0)	Imm12(0)	Enable deletion of current leaf from rope. 0 Do not delete leaf. 1 Delete leaf
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	Location of the current leaf address. The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary.
TSRx	26	Register		Contents of current leaf (address CLA in LUDefTable). TSRx is mapped into the Shared Memory pool, starting at an offset of 4 QW past the QW indicated by the input TSEDPA parameter for a length of 4 QW.

Table 8-62. ARDL Output Results

Result	Bit Length	Source	Description
TSRx	512	Shared Memory Pool	Contents of TSRx will not be destroyed
LCBA0	26	Register	Contents of LCBA0 have been destroyed
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.7 Tree Leaf Insert Rope (TLIR)

TLIR inserts a leaf into the rope. The leaf must already be stored in TSR0 (done automatically by picocode during TLIR) and the leaf address must already be available in LCBA0. TLIR maintains the rope, which involves updating the PVA field in LUDefTable, the NLARope leaf field in control store, and the NLARope leaf field stored in TSRx. The leaf is inserted into the rope ahead of the current leaf, which has address CLA. Field PLA is updated to the new leaf address, which is LCBA0 / 1, in LUDefTable. Following TLIR execution, picocode must invoke MWR to write the leaf into control store. The contents of TSR1 and LCBA1 can be destroyed because TLIR uses TSR1 and LCBA1 as a work area.

Table 8-63. TLIR Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable
LCBA0	26	Register		Address of leaf to be inserted into rope
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Only values of x'8', x'A', x'C', and x'E' should be used.
TSRx	26	Shared Memory Pool		Contents of leaf to be inserted into rope. TSRx is mapped into the Shared Memory pool, starting at an offset of 4 QW past the QW indicated by the input TSEDPA parameter for a length of 4 QW.

Table 8-64. TLIR Output Results

Result	Bit Length	Source	Description
TSRx	512	Shared Memory Pool	Leaf NLA field has been updated
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.8 Clear PSCB (CLRPSCB)

This command writes all zeros to PSCB0 / 1 / 2.

Table 8-65. CLRPSCB Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
PN	2	Imm16(1..0)	--	Selects PSCB0, PSCB1, or PSCB2 register

Table 8-66. CLRPSCB Output Results

Result	Bit Length	Source	Description
PSCB<PN>	--	Register	Set to all zeros
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.9 Read PSCB (RDPSCB)

RDPSCB reads a PSCB from the control store and stores it in one of the PSCB0 / 1 / 2 registers. For LPM, the entire PSCB is read from memory at the address given by PSCB<pn>.Addr and stored in PSCB<pn>. For FM, the entire PSCB is read from memory and converted into a LPM PSCB format.

Table 8-67. RDPSCB Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
PN	2	Imm16(1..0)	Imm12(1..0)	Selects PSCB0, PSCB1, or PSCB2 register
PSCB<PN>.Addr	26	Register		Address in control store of PSCB to be read
RdWrPSCB_Cntl	2	Imm16(3..2)	Imm12(3..2)	00 Result is based on PatBit value. PatBit = 0Branch 0 entry of the PSCB is read PatBit = 1Branch 1 entry of the PSCB is read 01 Branch 0 entry of the PSCB is read 10 Branch 1 entry of the PSCB is read 11 Branch 0 and branch 1 entry of the PSCB is read
RdWrPSC_ DT_Flag	1	Imm16(4)	Imm12(4)	Indicates entry is DT

Table 8-68. RDPSCB Output Results

Result	Bit Length	Source	Description
PSCB<PN>	--	Register	PSCB is read from control store and stored in register PSCB<pn>. NPA0, NBT0, LCBA0 and NPA1, NBT1, LCBA1 fields are changed. Remainders are not changed.
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.10 Write PSCB (WRPSCB)

WRPSCB writes a PSCB stored in PSCB0, 1, or 2 to the control store. For LPM, the entire PSCB is written to memory to the address given by PSCB<pn>.Addr. For FM, the PSCB is written to memory in FM PSCB format. An error flag is set when the PSCB is not in FM PSCB format. In both cases, WRPSCB generates the PSCB's two format bits. When the PSCB represents a DTEntry, only half of PSCB is written to memory. That is, the entire DTEntry is written.

Table 8-69. WRPSCB Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
PN	2	Imm16(1..0)	Imm12(1..0)	Selects PSCB0, PSCB1, or PSCB2 register
PSCB<PN>.Addr	26	Register		Address in control store of the PSCB to be written
RdWrPSCB_Cntl	2	Imm16(3..2)	Imm12(3..2)	00 Action is based on PatBit value. PatBit = 0Branch 0 entry of the PSCB is written PatBit = 1Branch 1 entry of the PSCB is written 01 Branch 0 entry of the PSCB is written 10 Branch 1 entry of the PSCB is written 11 Branch 0 and branch 1 entry of the PSCB is written
RdWrPSC_DT_Flag	1	Imm16(4)	Imm12(4)	Indicates entry is DT

8.2.8.11 Push PSCB (PUSHPSCB)

PUSHPSCB pushes the PSCB stack.

Table 8-70. PUSHPSCB Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
PSCB0	--	--		Contains a PSCB
PSCB1	--	--		Contains a PSCB

Table 8-71. PUSHPSCB Output Results

Result	Bit Length	Source	Description
PSCB2	--	Register	Set to PSCB1
PSCB1	--	Register	Set to PSCB0
PSCB0	--	Register	Set to all zeros
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.12 Distinguish (DISTPOS)

DISTPOS performs a pattern compare between the patterns stored in HashedKey and TSR0. The result is stored in the DistPosReg register. The OK flag is set when a full match has been detected.

Table 8-72. DISTPOS Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
HashedKey	192	Register		Contains hashed pattern
HashedKeyLen	8	Register		Contains length of hashed pattern minus 1
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', x'A', x'C', and x'E'.
TSRx	512	Shared Memory Pool		Contains second pattern with pattern length (for LPM only). TSRx is mapped into the Shared Memory pool, starting at an offset of 4 QW past the QW indicated by the input TSEDPA parameter for a length of 4 QW.

Table 8-73. DISTPOS Output Results

Result	Bit Length	Source	Description
OK/KO	1	Flag	0 Pattern does not match 1 Pattern in HashedKey matches pattern in TSRx
DistPos	8	Register	Smallest bit position where pattern in HashedKey differs from pattern in TSRx
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.13 TSR0 Pattern (TSR0PAT)

TSR0PAT reads a bit from the pattern stored in TSRx and stores this bit in the PatBit_TSR0 register.

Table 8-74. TSR0PAT Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
BitNum	8	--	GPR(7..0)	Selects bit in TSR0 pattern
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', x'A', x'C', and x'E'.

Table 8-75. TSR0PAT Output Results

Result	Bit Length	Source	Description
PatBit_TSR0	1	Register	Set to value of bit BitNum of pattern stored in TSR0
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.8.14 Pattern 2DTA (PAT2DTA)

PAT2DTA reads a pattern from TSRx, stores it in the HashedKey, and sets the DTA register accordingly. PAT2DTA does not perform a hash since the pattern in a leaf is already hashed. Pattern read from TSRx is assumed to be already hashed.

Table 8-76. PAT2DTA Input Operands

Operand	Bit Length	Operand Source		Description
		Direct	Indirect	
LUDefIndex	8	Imm16(12..5)	GPR(7..0)	Defines entry in LUDefTable used to calculate DTA from HashedKey
TSEDPA	4	Imm16(4..1)	Imm12(4..1)	The TSEDPA is the high order 4 bits of the thread's shared memory pool address (see *7.2.4 Shared Memory Pool* on page 193) and is constrained to be on a four-QW boundary. Use only values of x'8', X'A', X'C', and X'E'.

Table 8-77. PAT2DTA Output Results

Result	Bit Length	Source	Description
DTA	26	Register	DTEntry Address corresponding to DT definition in LUDefTable and HashedKey
OK/KO	1	Flag	0 KO: Unsuccessful Operation 1 OK: Successful Operation

8.2.9 Hash Functions

Table 8-78. General Hash Functions

Hash_type	Name	Description
0	No hash	No hash is performed and hashed output H(191..0) equals input key K(191..0). Can be used for SMT trees or LPM trees if 32-bit IP LPM hash cannot be used.
1	192-bit IP Hash	Uses four copies of IP hash box. See *Figure 8-10: 192-Bit IP Hash Function* on page 346.
2	192-bit MAC Hash	See *Figure 8-11: MAC Hash Function* on page 347.
3	192-bit Network DISTPOS	See *Figure 8-12: Network Dispatcher Hash Function* on page 348.
4	Reserved	
5	48-bit MAC swap	See *Figure 8-13: 48-Bit MAC Hash Function* on page 349.
6	60-bit MAC swap	See *Figure 8-14: 60-Bit MAC Hash Function* on page 350.
7	Reserved	
8	8-bit Hasher	See *Figure 8-15: 8-bit Hash Function* on page 351.
9	12-bit Hasher	See *Figure 8-16: 12-bit Hash Function* on page 352.
10	16-bit Hasher	See *Figure 8-17: 16 bit Hash Function* on page 353.
11-15	Reserved	Reserved.

In the following figures, the input is always the 192-bit key and the output is a 192-bit hashed output before color insertion. The Hash_type field of the LUDefTable defines the hasher to be used. If color is enabled, the color is inserted at the bit position given by DT_Size in the LUDefTable and 16 LSBs of the key are ignored, since a maximum key length of 176 bits is supported when color is enabled.

Figure 8-9. No-Hash Function

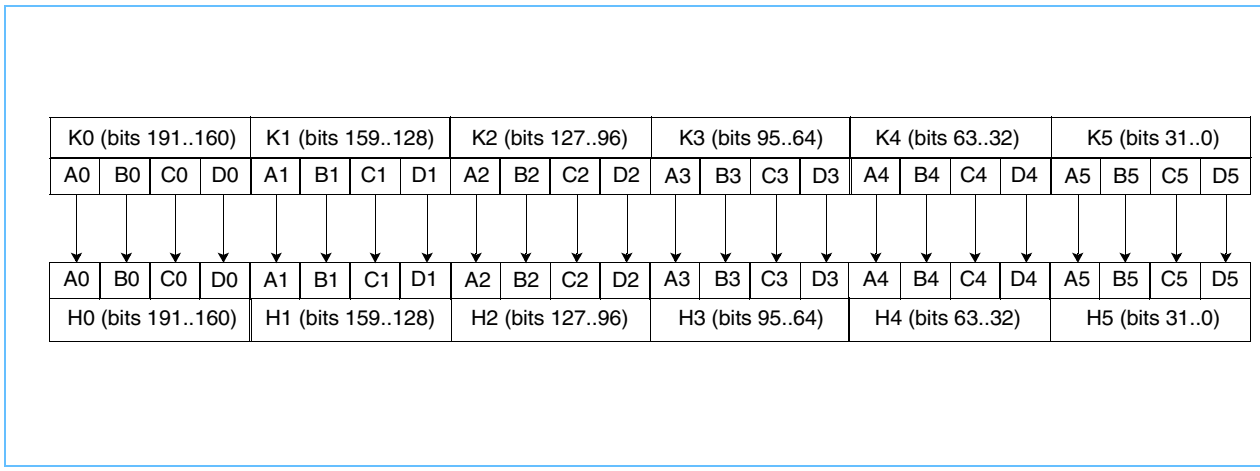

Figure 8-10. 192-Bit IP Hash Function

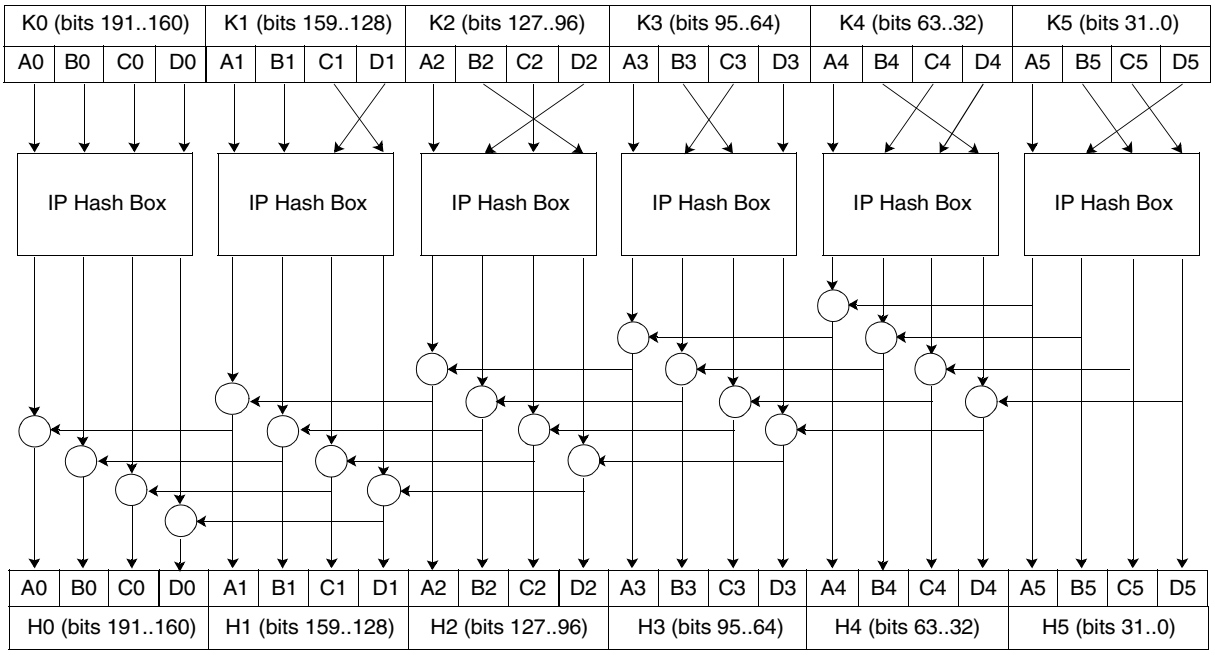

Figure 8-11. MAC Hash Function

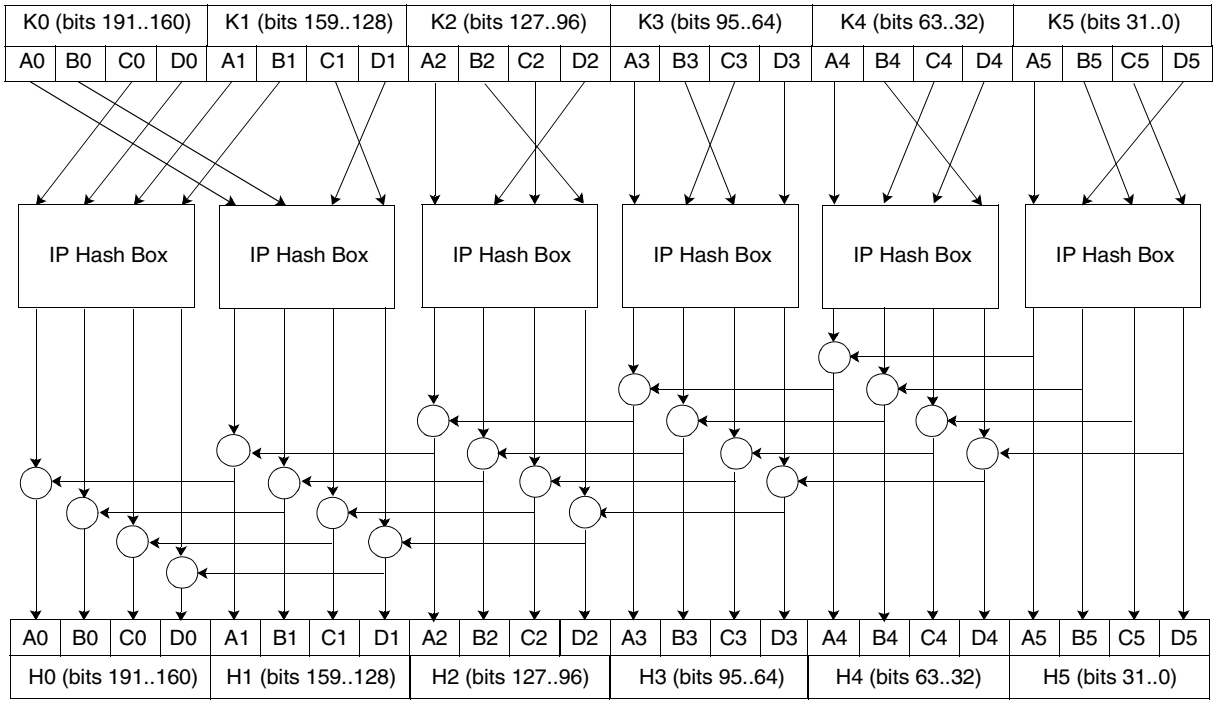

Figure 8-12. Network Dispatcher Hash Function

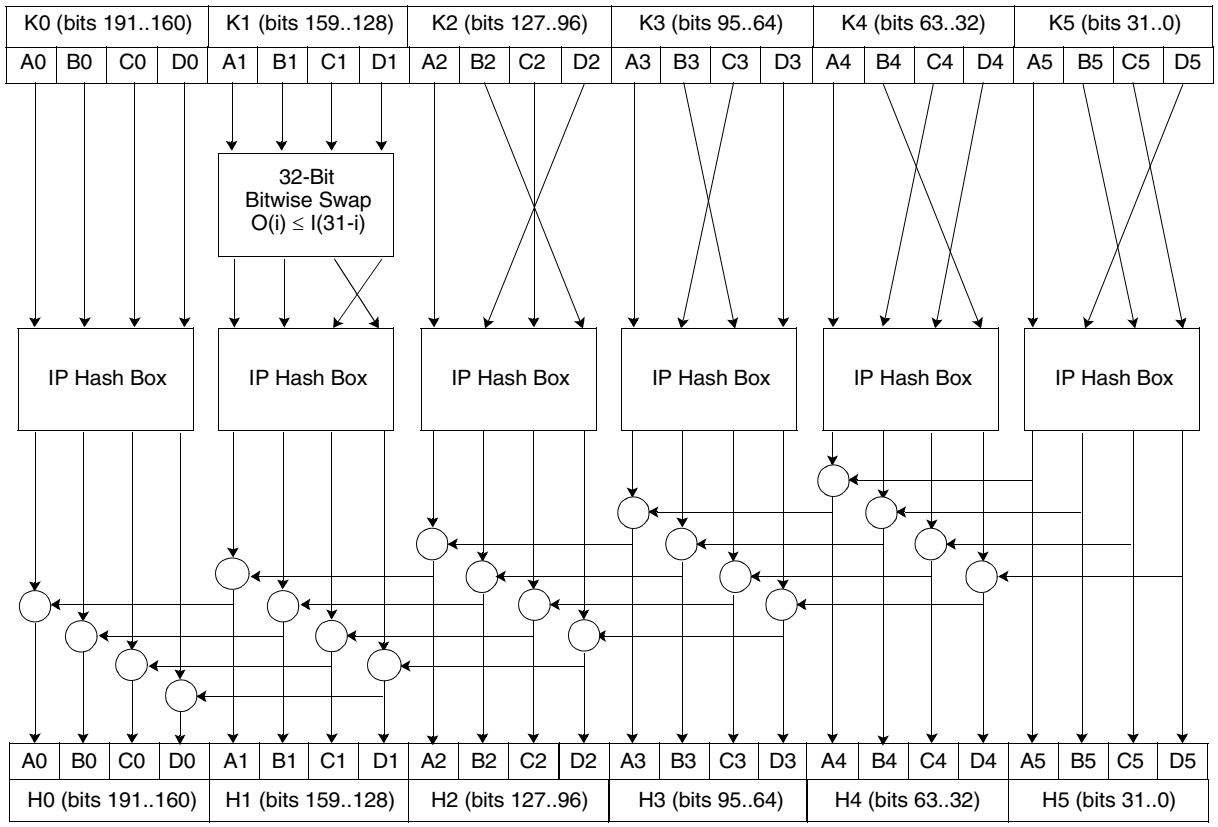

Figure 8-13. 48-Bit MAC Hash Function

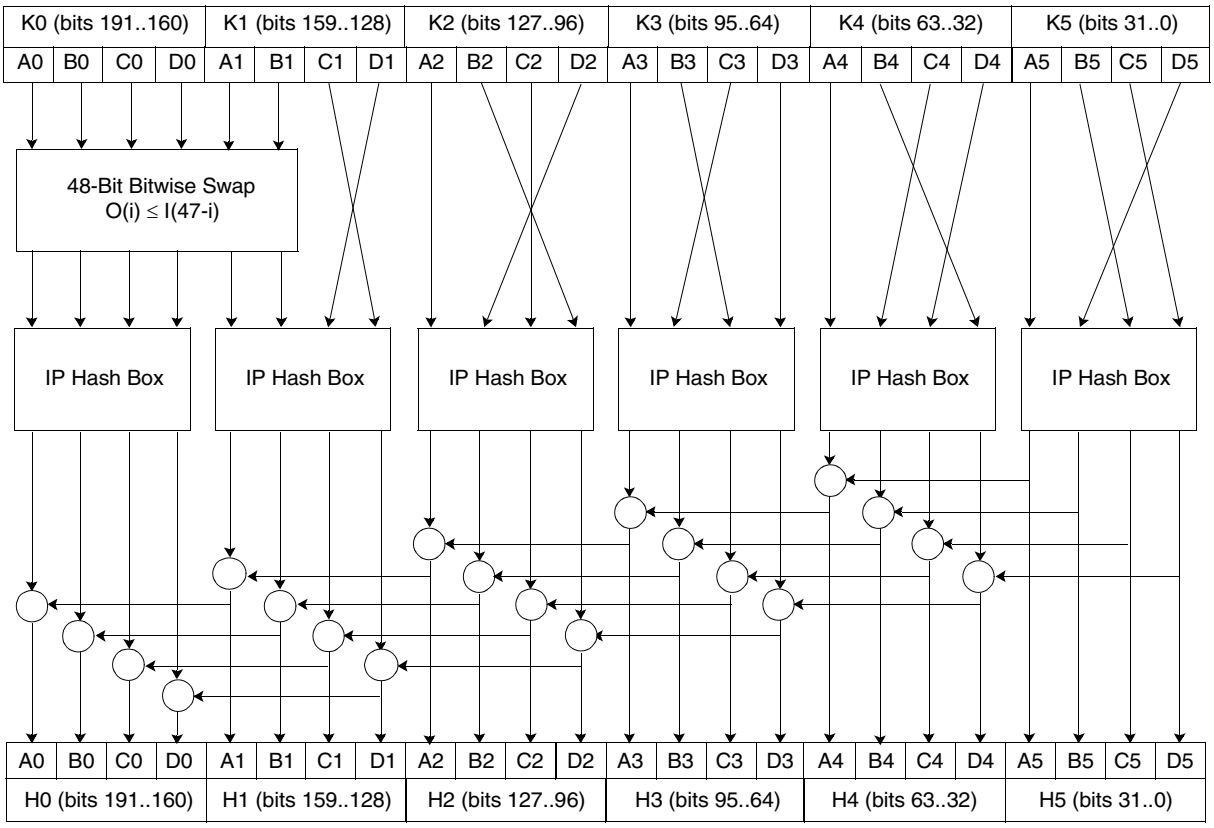

Figure 8-14. 60-Bit MAC Hash Function

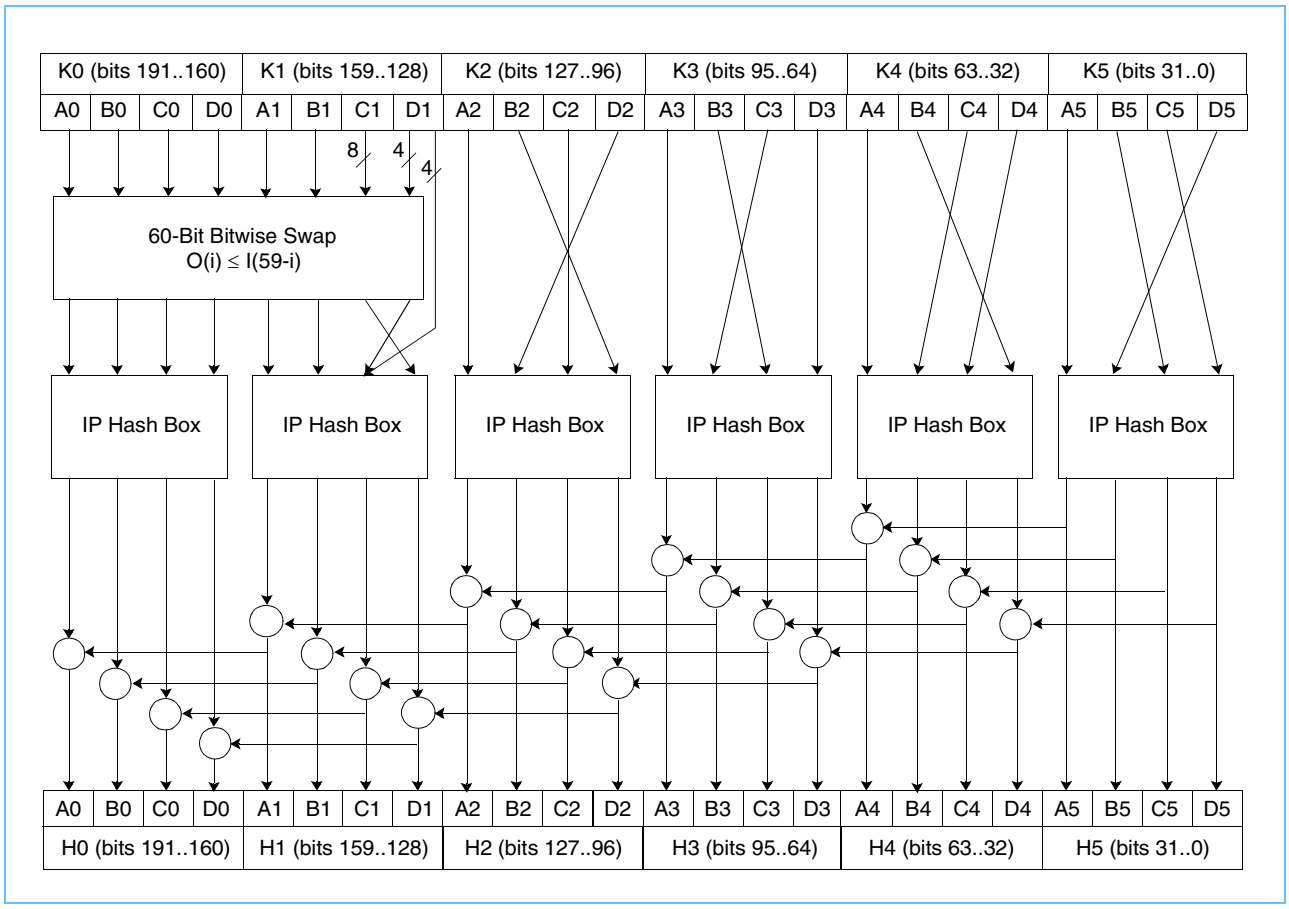

Figure 8-15. 8-bit Hash Function

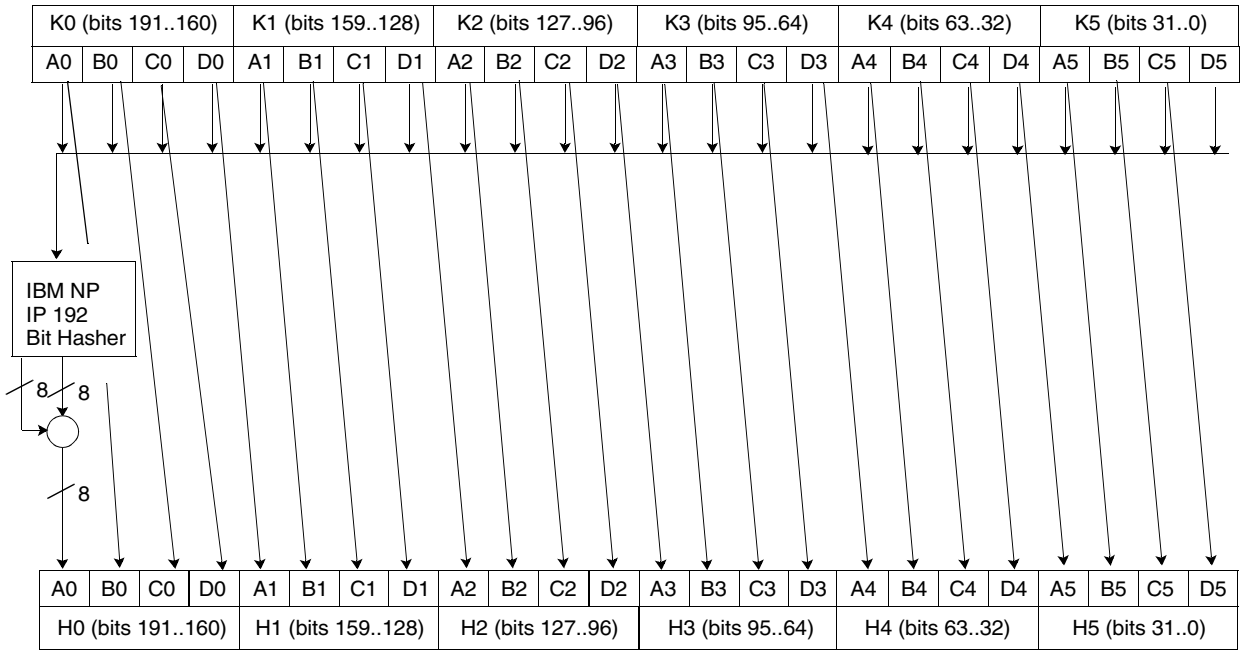
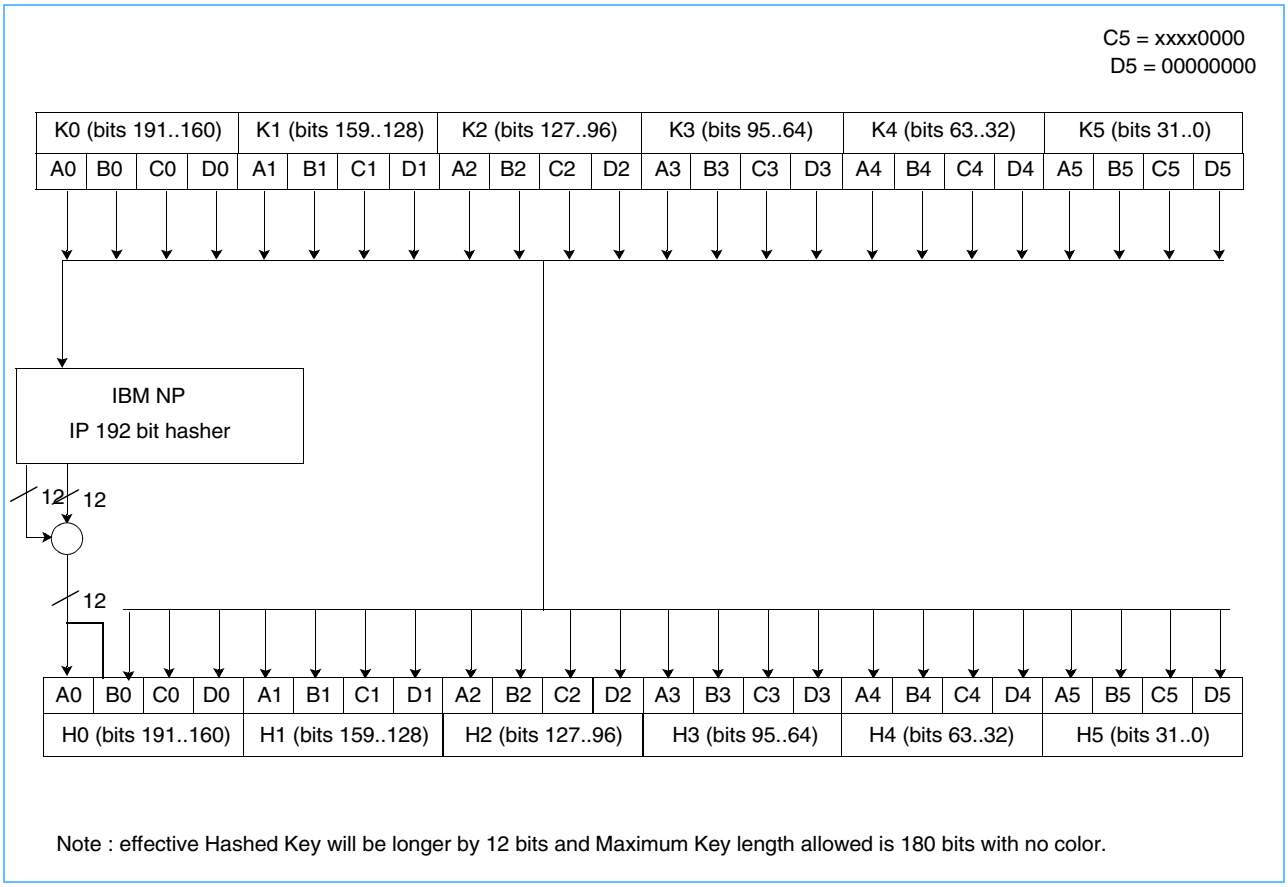


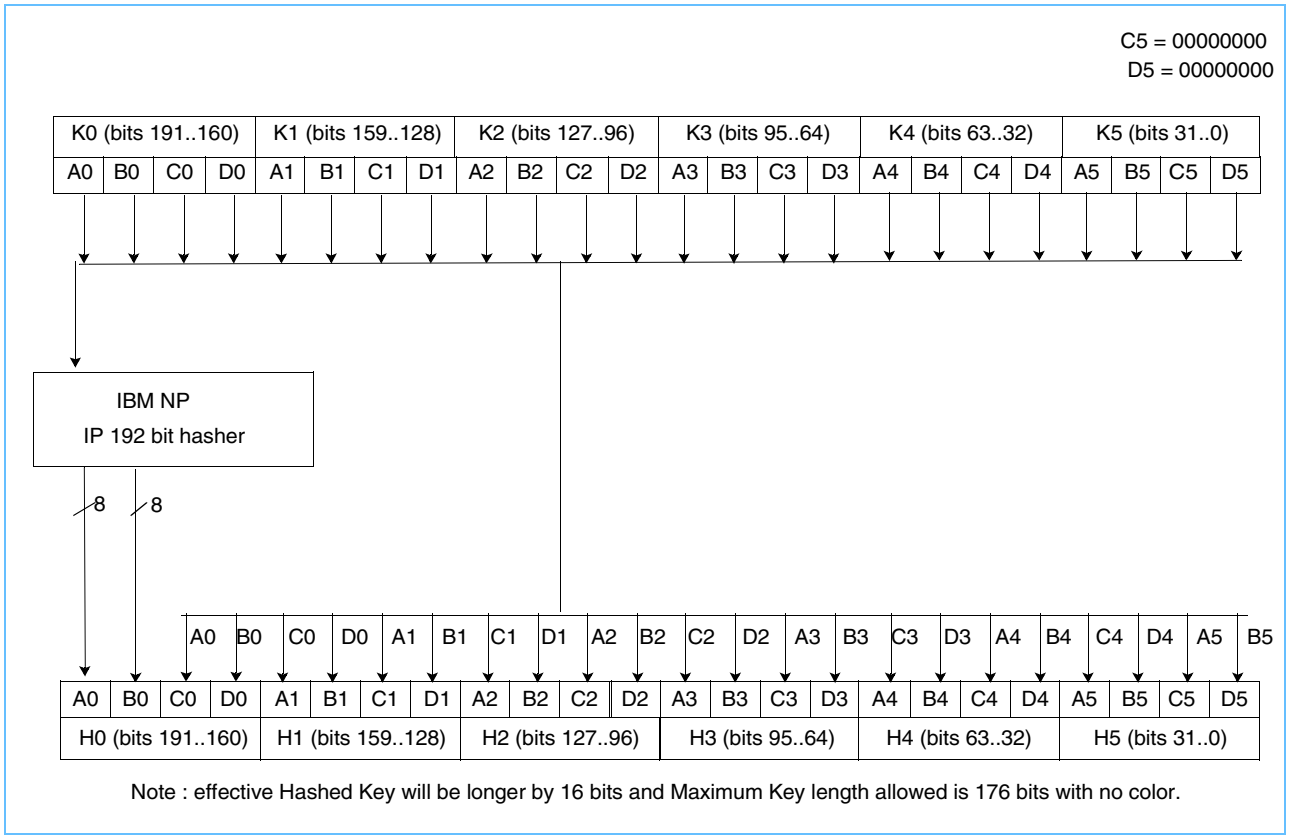
Note : effective Hashed Key will be longer by 8 bits and Maximum Key length allowed is 184 bits with no color.

Figure 8-16. 12-bit Hash Function



Note : effective Hashed Key will be longer by 12 bits and Maximum Key length allowed is 180 bits with no color.

Figure 8-17. 16 bit Hash Function



Note : effective Hashed Key will be longer by 16 bits and Maximum Key length allowed is 176 bits with no color.

9. Serial / Parallel Manager Interface

Located within the Embedded Processor Complex (EPC), the Serial / Parallel Manager (SPM) Interface is a serial interface for communication with external devices. The SPM Interface consists of a clock signal output, a bi-directional data signal, and an interrupt input. On this interface, the NP4GS3 is the master and the external SPM module is the only slave[1]. The SPM Interface loads picocode, allowing management of physical layer devices (PHYs) and access to card-based functions such as light-emitting diodes (LEDs).

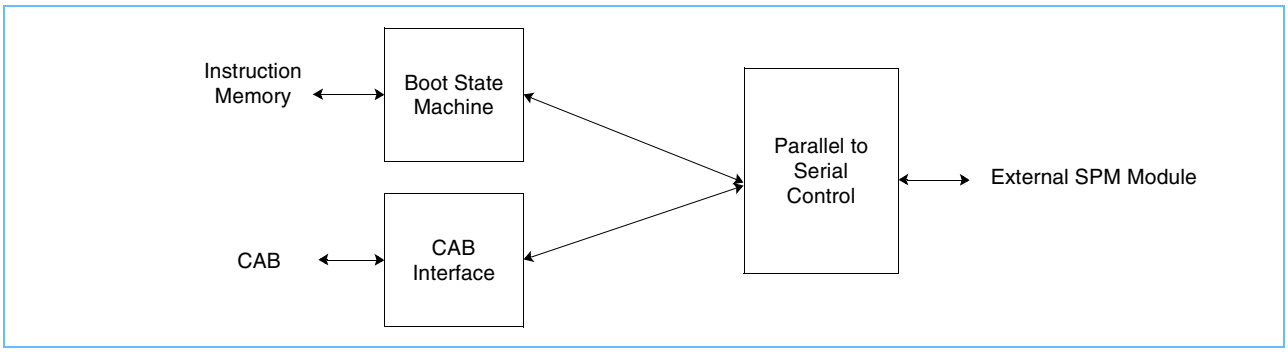
The SPM Interface supports:

- An external SPM module
- Boot code load via external SPM and EEPROM
- Boot override via CABWatch interface or Boot_Picocode configuration device I/O
- Access to external PHYs, LEDs, management, and card-based functions

9.1 SPM Interface Components

Figure 9-1 shows the functional blocks of the SPM Interface. The list following the figure describes them.

Figure 9-1. SPM Interface Block Diagram



Boot State Machine	Starts up after reset if configured to do so by an external I/O pin (Boot_Picocode set to 0). It selects one of two boot images (picocode loads) based on a configuration flag found in the EEPROM and places the code into the instruction memory in the EPC. Once the code is loaded, the Boot State Machine causes an interrupt that starts up the Guided Frame Handler (GFH) thread, which executes the loaded code.
CAB Interface	A memory mapped interface to the NP4GS3 that allows the protocol processors to access any external device, including an SPM module, external PHYs, or card LEDs.
Parallel to Serial Control	Converts between the internal 32-bit read/write parallel interface and the 3-bit external bi-directional serial interface.

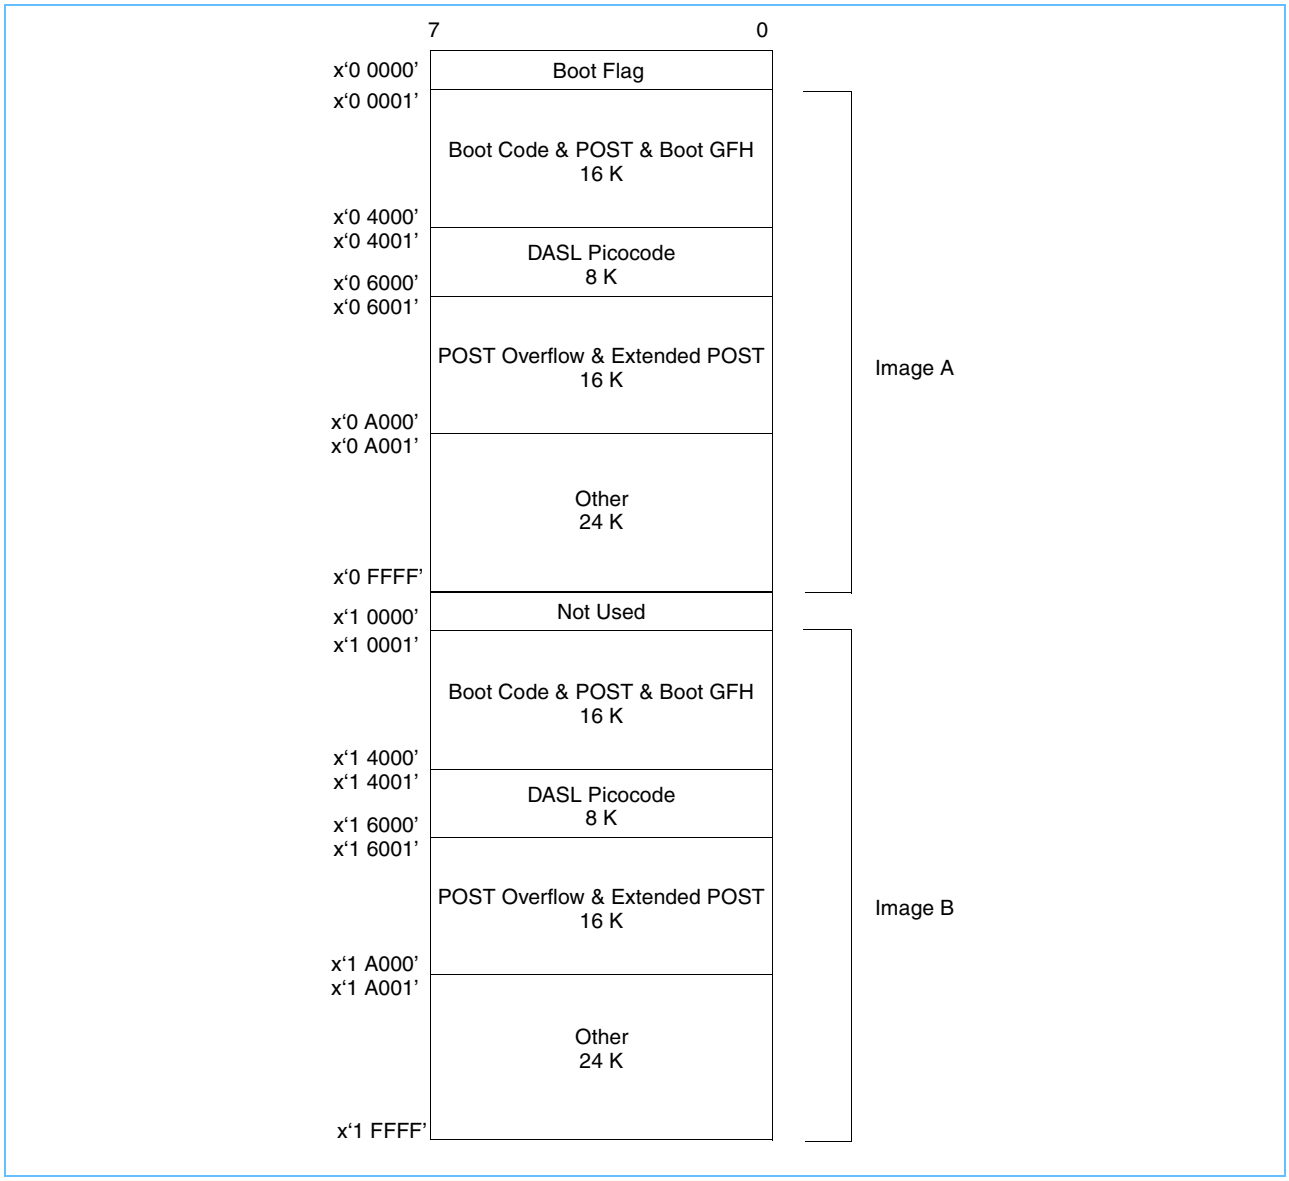
1.IBM does not supply the external SPM module.

9.2 SPM Interface Data Flow

The SPM Interface is used initially to boot the NP4GS3. Following a reset, the SPM Interface reads an external EEPROM and loads the EEPROM's contents into the EPC's Instruction Memory. When loading is complete, the SPM Interface causes a POR interrupt that causes the Guided Frame Handler (GFH) to start executing the boot code. The boot code initializes the network processor's internal structures and configures all the interfaces that the network processor requires to operate. When all boot processing is complete, the GFH activates the $\overline{\text{operational}}$ signal to indicate its availability to the control point function (CPF). The CPF sends guided frames to further initialize and configure the network processor, preparing it for network operation.

The Boot State Machine supports two images of boot code in external EEPROM (see *Figure 9-2*). The contents of byte x'0 0000' in EEPROM is examined during the read process to determine which image to load. When the most significant bit of this byte is a '0', the current image resides at addresses x'0 0001' - x'0 4000'. Otherwise, the current image resides at addresses x'1 0001' - x'1 4000'. The Boot State Machine will load the appropriate image and allow the other image area to be used for boot code updates.

Figure 9-2. EPC Boot Image in External EEPROM

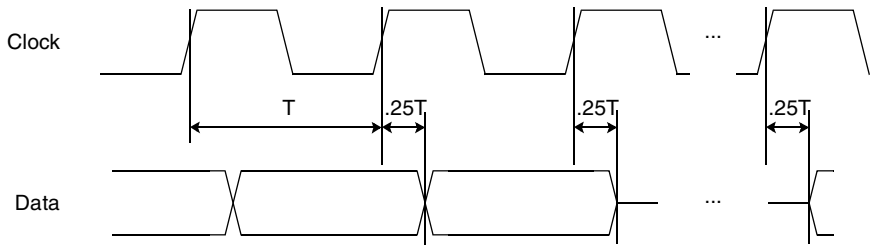


The SPM Interface is also used during initialization and statistics gathering. It interfaces with the Ethernet PHYs, card LEDs, and other card-level structures through an external SPM interface module supplied by the customer. These external structures are mapped to the Control Access Bus (CAB) address space and are accessed from the picocode using the same methods as those used to access any internal data structures: the picocode issues reads or writes to the appropriate address and the SPM Interface converts these reads and writes to serial communications with the external SPM module. The external SPM module re-converts these serial communications to register reads and writes and to access the desired card device. Through the SPM interface, the picocode has indirect access to all card-level functions and can configure or gather statistics from these devices as if they were directly attached to the CAB interface.

9.3 SPM Interface Protocol

The SPM Interface operates synchronously with the 33-MHz clock signal output. Data, address, and control information is transferred serially on a bidirectional data signal. Transitions on this data signal occur at the rising edges of the clock signal. Each data exchange is initiated by the NP4GS3 and can be one to four bytes in length. *Figure 9-3* illustrates the timing of the SPM Interface.

Figure 9-3. SPM Bit Timing



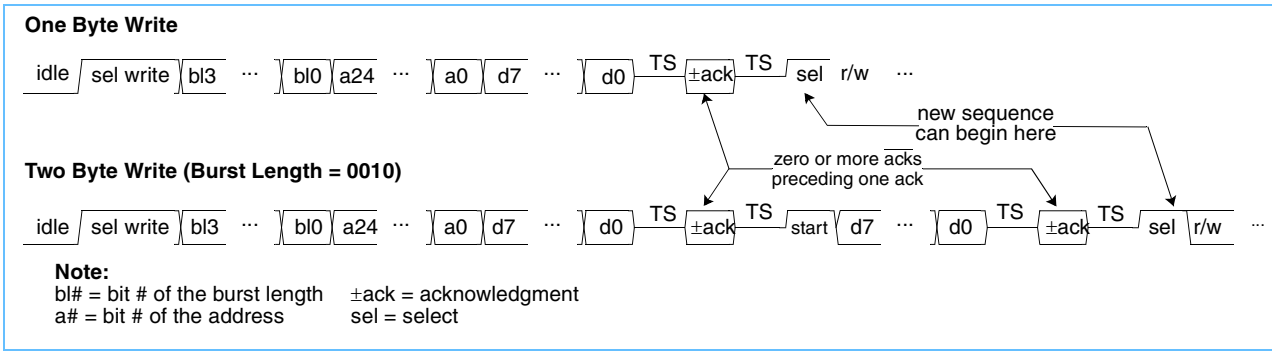
For single-byte transfers, the exchange begins when the NP4GS3 drives the data signal to '1' for one clock period. This "select" indication is followed by a 1-bit write/$\overline{\text{read}}$ indication, a 4-bit burst length indication, and a 25-bit address value.

For read and write transfers, the SPM Interface master waits for a response from the SPM Interface slave, and the slave communicates with the master using the following acknowledgments:

- ack: a '1' driven onto the data bus by the SPM Interface slave to indicate each successful byte operation, either read or write.
- $\overline{\text{ack}}$: a '0' driven onto the data bus by the SPM Interface slave while the byte operation is in progress.

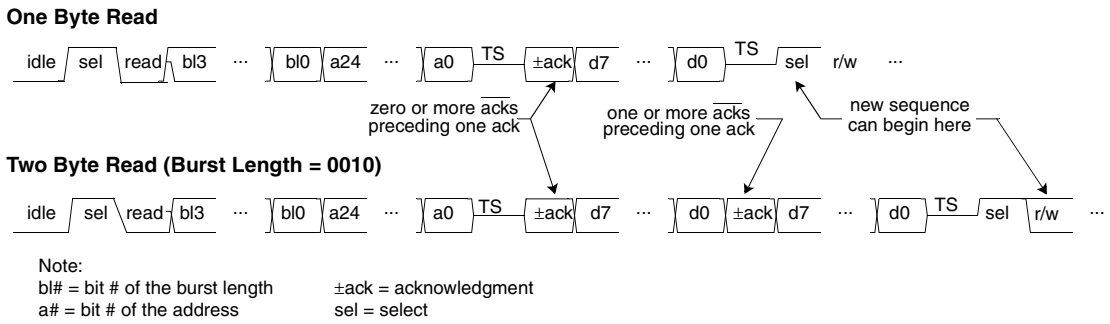
For write transfers (see *Figure 9-4*), the address is followed immediately by eight bits of data. The NP4GS3 puts its driver in High-Z mode. One clock period later, the slave drives the data signal to '0' ($\overline{\text{ack}}$) until the byte write operation is complete. The slave then drives the data signal to '1' (ack). During the byte write operation, the NP4GS3 samples the data input looking for a '1' (ack). Immediately following the ack, the slave puts its driver in High-Z mode. The transfer is concluded one clock period later.

Figure 9-4. SPM Interface Write Protocol



For read transfers (see *Figure 9-5*), the address is followed by the NP4GS3 putting its driver into High-Z mode. One clock period later, the slave drives the data signal to '0' ($\overline{ack}$) until the byte of read data is ready for transfer. The slave then drives the data signal to '1' (ack). During this time, the NP4GS3 samples the data input looking for an ack. Immediately following the ack, the slave drives the eight bits of data onto the data signal and then puts its driver in High-Z mode. The transfer is concluded one clock period later.

Figure 9-5. SPM Interface Read Protocol



The protocol for multiple byte transfers is similar, except that each byte written is accompanied by a bus turn-around, zero or more $\overline{acks}$, and an ack. Read bursts are characterized by the slave retaining bus ownership until the last byte of the burst is transferred. Each successive byte read is preceded by at least one '0' on the data bus followed by one '1' on the data bus (ack), and immediately followed by the eight bits of data.

9.4 SPM CAB Address Space

The SPM Interface enables the control access bus (CAB) to access an external EEPROM and other devices attached via an external SPM module developed by the customer. The address space is divided into three areas:

- Byte access
- Word access
- EEPROM access

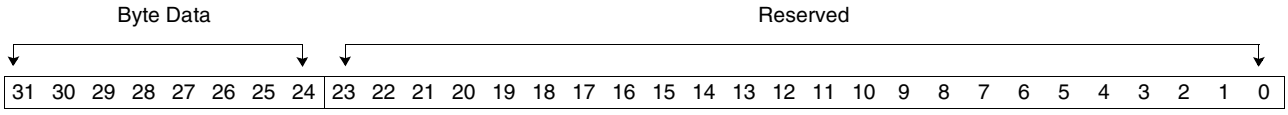
9.4.1 Byte Access Space

All elements accessed in byte access space are limited to a single byte in width.

Access Type R/W

Base Addresses x‘2800 0000’ through x‘281F FFFF’

x‘2880 0000’ through x‘28FF FFFF’



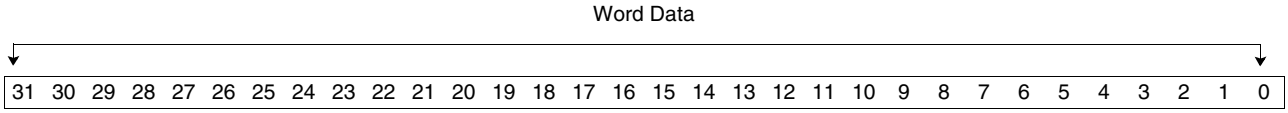
Field Name	Bit(s)	Reset	Description
Byte Data	31:24		Data at this location
Reserved	23:0		Reserved

9.4.2 Word Access Space

All elements accessed in word access space are a word in width.

Access Type: R/W

Base Addresses: x‘2820 0000’ through x‘287F FFFF’



Field Name	Bit(s)	Reset	Description
Word Data	31:0		Data at this location

9.4.3 EEPROM Access Space

The SPM Interface and a customer-supplied external SPM module can be combined to provide access to an attached EEPROM. The EEPROM access space contains locations for 16 M 1-byte elements. All write accesses are limited to a single byte, but read accesses may be in bursts of 1, 2, 3, or 4 bytes. The CAB address is formed using the field definitions shown in *Table 9-1*.

Table 9-1. Field Definitions for CAB Addresses

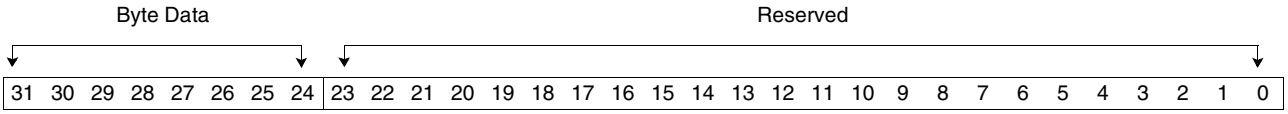
Bits	Description
31:27	'00101'
26:25	Encoded burst length 00 4-byte burst (read only) 01 1-byte burst (read or write) 10 2-byte burst (read only) 11 3-byte burst (read only)
24	'1'
23:0	Starting Byte address for read or write action

9.4.3.1 EEPROM Single-Byte Access

Addresses in this space are used for single-byte read or write access to the EEPROM.

Access Type: R/W

Base Addresses: x'2B00 0000' through x'2BFF FFFF'



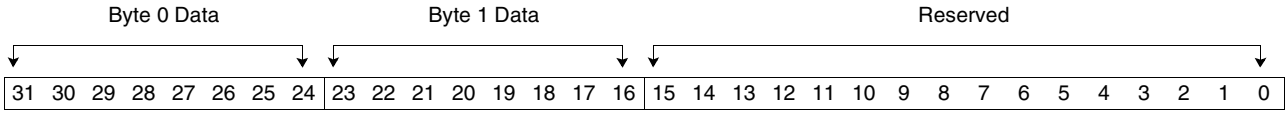
Field Name	Bit(s)	Reset	Description
Byte Data	31:24		Data at starting byte address
Reserved	23:0		Reserved

9.4.3.2 EEPROM 2-Byte Access

Addresses in this space are used for a 2-byte read burst access to the EEPROM.

Access Type: Read Only

Base Addresses: x‘2D00 0000’ through x‘2DFF FFFF’



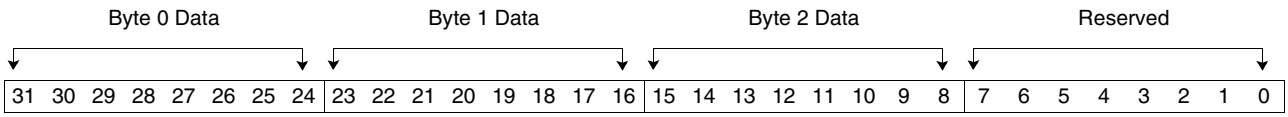
Field Name	Bit(s)	Reset	Description
Byte 0 Data	31:24		Data at starting byte address
Byte 1 Data	23:16		Data at starting byte address + 1
Reserved	15:0		Reserved

9.4.3.3 EEPROM 3-Byte Access

Addresses in this space are used for a 3-byte read burst access to the EEPROM.

Access Type: Read Only

Base Addresses: x‘2F00 0000’ through x‘2FFF FFFF’



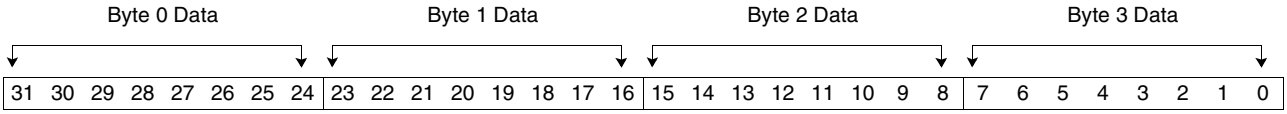
Field Name	Bit(s)	Reset	Description
Byte 0 Data	31:24		Data at byte address
Byte 1 Data	23:16		Data at byte address + 1
Byte 2 Data	15:8		Data byte address + 2
Reserved	7:0		Reserved

9.4.3.4 EEPROM 4-Byte Access

Addresses in this space are used for a 4-byte read burst access to the EEPROM.

Access Type: Read only

Base Addresses: x‘2900 0000’ through x‘29FF FFFF’



Field Name	Bit(s)	Reset	Description
Byte 0 Data	31:24		Data at byte address
Byte 1 Data	23:16		Data at byte address + 1
Byte 2 Data	15:8		Data byte address + 2
Byte 3 Data	7:0		Data byte address + 3

10. Embedded PowerPC™ Subsystem

10.1 Description

The IBM PowerNP NP4GS3 incorporates an embedded PowerPC subsystem. This subsystem consists of mixture of macros from IBM's PowerPC macro library and other components that were designed specifically for the NP4GS3.

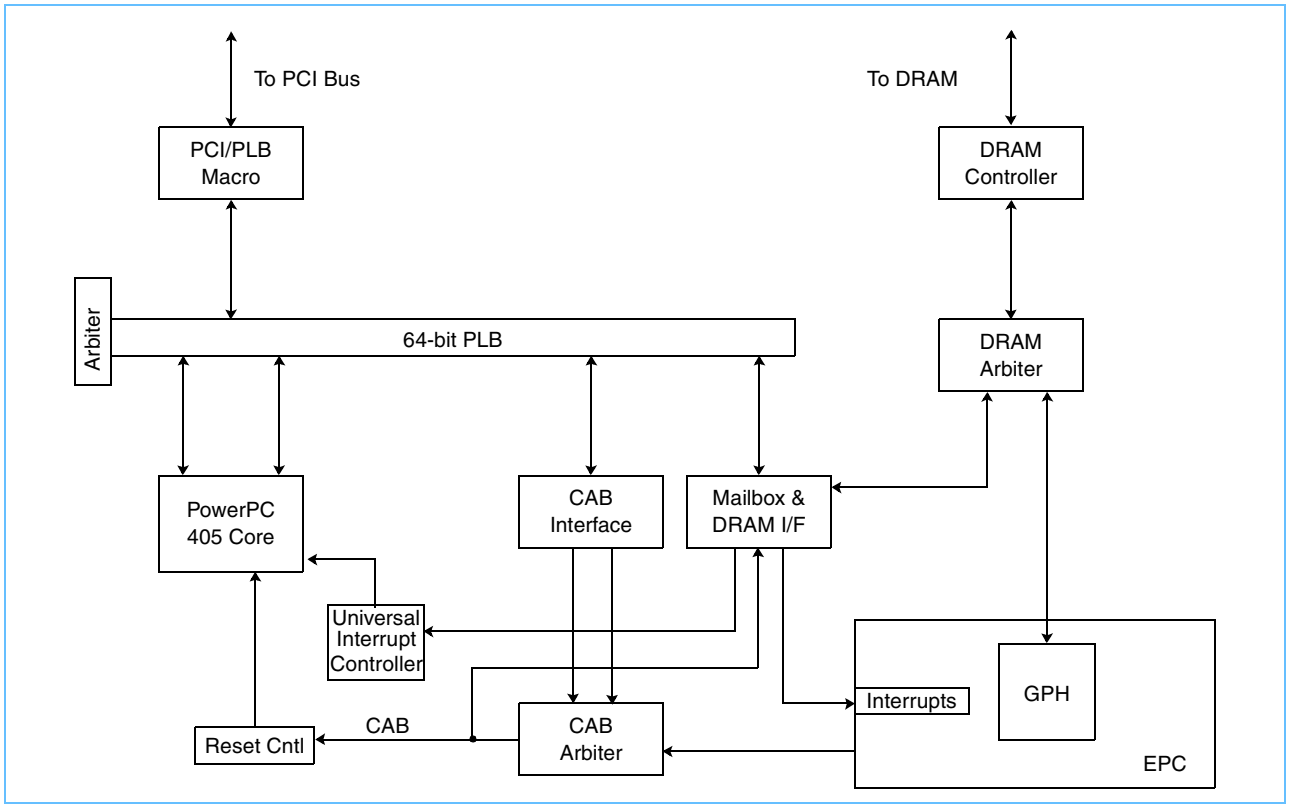
Standard IBM PowerPC macros include the following:

- 133 MHz PPC405 Processor Core with 16 K of instruction cache and 16 K of data cache
- 133 MHz, 64-bit PLB macro with PLB arbiter
- 33/66 MHz, 32-bit PCI to 133 MHz, 64-bit PLB macro
- PowerPC Universal Interrupt Controller (UIC) macro

Documentation for the above macros is contained in the *IBM PowerPC 405GP Embedded Processor User's Manual* (http://www-3.ibm.com/chips/techlib/techlib.nsf/products_PowerPC_405GP_Embedded_Processor) and is not repeated here. That document also contains information for other macro library components not contained in the NP4GS3 which does not apply to the above macros.

The embedded PowerPC subsystem includes a CAB Interface PLB slave unit to access NP4GS3 internal structures and a Mailbox and DRAM Interface PLB slave unit for inter-processor communications and access to PowerPC instructions.

Figure 10-1. PowerPC Subsystem Block Diagram



10.2 Processor Local Bus and Device Control Register Buses

The on-chip bus structure consisting of the Processor Local Bus (PLB) and the Device Control Register bus (DCR) provides a link between the processor core and the other peripherals (PLB master and slave devices) used in PowerPC subsystem design.

The PLB is the high performance bus used to access memory, PCI devices, and NP4GS3 structures through the PLB interface units. The PLB interface units shown in *Figure 10-1*, the CAB Interface and the Mailbox & DRAM interface, are PLB slaves. The processor core has two PLB master connections, one for instruction cache and one for data cache. The PCI to PLB interface unit, which is both a PLB master and PLB slave device, is also attached to the PLB. The PLB master corresponds to the PCI target and the PLB slave corresponds to the PCI master.

Each PLB master is attached to the PLB through separate address, read data, and write data buses and a plurality of transfer qualifier signals. PLB slaves are attached to the PLB through shared, but decoupled, address, read data, and write data buses and a plurality of transfer control and status signals for each data bus.

Access to the PLB is granted through a central arbitration mechanism that allows masters to compete for bus ownership. This mechanism is flexible enough to provide for the implementation of various priority schemes. Additionally, an arbitration locking mechanism is provided to support master-driven atomic operations.

The PLB is a fully-synchronous bus. Timing for all PLB signals is provided by a single clock source that is shared by all masters and slaves attached to the PLB.

Table 10-1. PLB Master Connections

Master ID	Master Unit Description
0	Processor Core Instruction Cache Unit
1	Processor Core Data Cache Unit
2	PLB/PCI Macro Unit
Others	Unused

All PLB arbiter registers are device control registers. They are accessed by using the Move From Device Control Register (mfdcr) and Move To Device Control Register (mtdcr) instructions. PLB arbiter registers are architected as 32-bits and are privileged for both read and write. The DCR base address of the PLB registers is x'080'. The DCR base address of the UIC registers is x'0C0'. Details regarding the PLB and UIC device control registers can be found in the *IBM PowerPC 405GP Embedded Processor User's Manual* (http://www-3.ibm.com/chips/techlib/techlib.nsf/products_PowerPC_405GP_Embedded_Processor).

The Device Control Register (DCR) bus is used primarily to access status and control registers within the PLB and the Universal Interrupt Controller (UIC). The DCR bus architecture allows data transfers among peripherals to occur independently from, and concurrent with, data transfers between the processor and memory or among other PLB devices.

10.3 Universal Interrupt Controller (UIC)

The Universal Interrupt Controller (UIC) provides all the necessary control, status, and communication between the various of interrupts sources and the microprocessor core. The UIC supports six on-chip and two external sources of interrupts. Status reporting (using the UIC Status Register (UICSR)) is provided to ensure that systems software can determine the current and interrupting state of the system and respond appropriately. Software can generate interrupts to simplify software development and for diagnostics.

The interrupts can be programmed, using the UIC Critical Register (UICCR), to generate either a critical or a non-critical interrupt signal.

The UIC supports internal and external interrupt sources as defined in Table 10-2.

Table 10-2. UIC Interrupt Assignments

Interrupt	Polarity	Sensitivity	Interrupt Source
0	High	Edge	DRAM D6 Parity Error
1	Programmable	Programmable	External Interrupt 0 (PCI_Bus_NM_Int input pin)
2	Programmable	Programmable	External Interrupt 1 (PCI_Bus_M_Int input pin)
3	High	Level	PCI Host to PowerPC Doorbell Interrupt
4	High	Level	PCI Host to PowerPC Message Interrupt
5	High	Level	Embedded Processor Complex to PowerPC Doorbell Interrupt
6	High	Level	Embedded Processor Complex to PowerPC Message Interrupt
7	High	Level	PCI Command Write Interrupt generated when an external PCI master writes to the PCI Command Register or bit 13 of the Bridge Options 2 Register is set to '1' via PCI configuration. See description of the PCI macro's Bridge Options 2 Register in the PPC405GP Embedded Controller User's Manual for details.
8-31	High	Level	unused, interrupt input to UIC tied low.

The on-chip interrupts (interrupts 0, and 3-7) and the external interrupts (interrupts 1-2) are programmable. However, the on-chip interrupts must be programmed as shown in Table 10-2. For details regarding the control of the UIC, including the programming of interrupts, see the *IBM PowerPC 405GP Embedded Processor User's Manual* (http://www-3.ibm.com/chips/techlib/techlib.nsf/products_PowerPC_405GP_Embedded_Processor).

10.4 PCI/PLB Macro

The Peripheral Component Interconnect (PCI) interface controller provides an interface for connecting PLB-compliant devices to PCI devices. The controller complies with PCI Specification, version 2.2. (http://www.pcisig.com).

Values of the PCI Device Configuration Header for the NP4GS3 are initialized by hardware.These values are shown in *Table 10-3*. When the boot picocode is loaded from the Management Bus (Boot_Picocode is tied to '0') and the PowerPC subsystem boots from DRAM D6 (Boot_PPC is tied to '0', see *2.1.8 Miscellaneous Pins on page 77*), a general reset initializes the PCI/PLB macro's Bridge Options 2 Register (PCIBRDGOPT2) with its Host Configuration Enable bit set to '0' (disabled). This allows the PowerPC subsystem to alter the contents of the PCI Device Configuration Header registers prior to access by external configuration. The PowerPC code then enables external host configuration.

Table 10-3. NP4GS3 PCI Device Configuration Header Values

Register Name	Register Value
Vendor ID	x'1014'
Device ID	x'01E8'
Revision ID	x'00'
Class Code	x'028000'
Subsystem ID	x'0000"
Subsystem Vendor ID	x'0000'

The PCI/PLB macro responds as a target on the PLB bus in several address ranges. These ranges allow a PLB master to configure the PCI/PLB macro, and to cause the PCI/PLB macro to generate memory, I/O, configuration, interrupt acknowledge, and special cycles to the PCI bus. Table 10-4 shows the address map from the view of the PLB, that is, as decoded by the PCI/PLB macro as a PLB slave.

Table 10-4. PLB Address Map for PCI/PLB Macro (Page 1 of 2)

PLB Address Range	Description	PCI Address Range
x'E800 0000' - x'E800 FFFF'	PCI I/O Accesses to this range are translated to an I/O access on PCI in the range 0 to 64 KB - 1	x'0000 0000' - x'0000 FFFF'
x'E801 0000 x'E87F FFFF'	Reserved PCI/PLB Macro does not respond (Other bridges use this space for non-contiguous I/O).	
x'E880 0000' - x'EBFF FFFF'	PCI I/O Accesses to this range are translated to an I/O access on PCI in the range 8 MB to 64 MB - 1	x'0080 0000' - x'03FF FFFF'
x'EC00 0000' - x'EEBF FFFF'	Reserved PCI Macro does not respond	
x'EEC0 0000' - x'EECF FFFF'	PCICFGADR and PCICFGDATA x'EEC0 0000': CONFIG_ADDRESS x'EEC0 0004': CONFIG_DATA x'EEC0 0008' - x'EECF FFFF': Reserved (can mirror PCICFGADR and PCICFGDATA)	

Table 10-4. PLB Address Map for PCI/PLB Macro (Page 2 of 2)

PLB Address Range	Description	PCI Address Range
x‘EED0 0000’ - x‘EEDF FFFF‘	PCI Interrupt Acknowledge and Special Cycle x‘EED0 0000’ read: Interrupt Acknowledge x‘EED0 0000’ write: Special Cycle x‘EED0 0004’ - x‘EEDF FFFF’: Reserved (can mirror Interrupt acknowledge and Special Cycle)	
x‘EEE0 0000’ - x‘EF3F FFFF’	Reserved PCI/PLB Macro does not respond	
x‘EF40 0000’ - x‘EF4F FFFF’	PCI/PLB Macro Local Configuration Registers x‘EF40 0000’: PMM0LA x‘EF40 0004’: PMM0MA x‘EF40 0008’: PMM0PCILA x‘EF40 000C’: PMM0PCIHA x‘EF40 0010’: PMM1LA x‘EF40 0014’: PMM1MA x‘EF40 0018’: PMM1PCILA x‘EF40 001C’: PMM1PCIHA x‘EF40 0020’: PMM2LA x‘EF40 0024’: PMM2MA x‘EF40 0028’: PMM2PCILA x‘EF40 002C’: PMM2PCIHA x‘EF40 0030’: PTM1MS x‘EF40 0034’: PTM1LA x‘EF40 0038’: PTM2MS x‘EF40 003C’: PTM2LA x‘F400 0400’ - x‘EF4F FFFF’: Reserved (can mirror PCI local registers)	
x‘0000 0000’ - x‘FFFF FFFF’	PCI Memory - Range 0 PMM 0 registers map a region in PLB space to a region in PCI memory space. The address ranges are fully programmable. The PCI address is 64 bits.	x‘0000 0000 0000 0000’ x‘FFFF FFFF FFFF FFFF’
x‘0000 0000’ - x‘FFFF FFFF’	PCI Memory - Range 1 PMM 1 registers map a region in PLB space to a region in PCI memory space. The address ranges are fully programmable. The PCI address is 64 bits.	x‘0000 0000 0000 0000’ x‘FFFF FFFF FFFF FFFF’
x‘0000 0000’ - x‘FFFF FFFF’	PCI Memory - Range 2 PMM 2 registers map a region in PLB space to a region in PCI memory space. The address ranges are fully programmable. The PCI address is 64 bits.	x‘0000 0000 0000 0000’ x‘FFFF FFFF FFFF FFFF’

Following a general reset of the NP4GS3, the PCI Target Map 1 is enabled for a PCI address range of 128 KB and is mapped to the PLB address range of x’7800 0000 to x‘7801 FFFF’. The corresponding PCI base address for this range must be set by PCI configuration of the PCI PTM1 Base Address Register. Likewise, the PCI Target Map 2 is enabled for a PCI address range of 128 MB and is mapped to the PLB address range of x’0000 0000 to x‘07FF FFFF’. The corresponding PCI base address for this range must be set by PCI configuration of the PCI PTM2 Base Address Register.

The PCI/PLB macro has a mode that enables a PLB master to access a PCI memory range without initial configuration cycles. This mode is enabled by strapping the boot_ppc input pin high. System designers, for instance, may use this mode to allow a processor to access a boot ROM in PCI memory space. In this mode the PCI/PLB macro comes out of reset with PMM0 enabled and programmed for the address range x’FFFE 0000’ - x’FFFF FFFF’. The ME field of the PCI Command register (PCICMD[ME]) is also set to 1 after reset. Enabling PCI boot mode does not prevent subsequent updates to the PMM0 registers.

Unless the boot picocode is loaded from the SPM (Boot_Picocode tied to '0') and the PowerPC subsystem boots from DRAM D6 (Boot_PPC tied to '0'), a general reset initializes the PCI/PLB macro's Bridge Options 2 Register (PCIBRDGOPT2) with its Host Configuration Enable bit set to '1' (enabled). This allows an external source to access the PCI/PLB macro's configuration registers. Otherwise, PowerPC code must enable external host configuration and may alter the contents of the PCI Device Configuration Header registers prior to enabling external host configuration.

For further details regarding the PCI/PLB macro's control and configuration registers, see the *IBM PowerPC 405GP Embedded Processor User's Manual* (http://www-3.ibm.com/chips/techlib/techlib.nsf/products_PowerPC_405GP_Embedded_Processor).

10.5 PLB Address Map

Components of the embedded PowerPC subsystem are connected using the Processor Local Bus (PLB). These components recognize PLB address values as their own. These PLB address values are fixed by hardware. The PLB address map describes the association of PLB address values and the components that recognize them.

Table 10-5. PLB Address Map (Page 1 of 2)

Symbolic Address	PLB Address	Description	Access
CAB Interface Macro			
PwrPC_CAB_Addr	x'7800 0000'	PowerPC CAB Address Register	R/W
PwrPC_CAB_Data	x'7800 0008'	PowerPC CAB Data Register	R/W
PwrPC_CAB_Cntl	x'7800 0010'	PowerPC CAB Control Register	R/W
PwrPC_CAB_Status	x'7800 0018'	PowerPC CAB Status Register	R
PwrPC_CAB_Mask	x'7800 0020'	PowerPC CAB Mask Register [NP4GS3B (R2.0) Only]	R/W
PwrPC_CAB_WUM_Data	x'7800 0028'	PowerPC CAB Write Under Mask Data Register [NP4GS3B (R2.0) Only]	W

Msg_Status	x‘3801 4000’	Message Status Register	R

1. Additional action occurs on register access using the specified address. Refer to register detailed section for more information.

10.7 CAB Interface Macro

The CAB Interface macro provides duplicate facilities to support independent CAB access of IBM Network Processor control and status facilities by the PCI Host processor and the embedded PowerPC subsystem. Exclusive access to these facilities, if required, is enforced through software discipline.

The PCI Host Processor can access the IBM Network Processor's CAB Interface through the following mechanism: after PCI configuration, one or more ranges of PCI addresses are mapped to PLB addresses. Accessing these PCI addresses also accesses PowerPC PLB resources, which include the following CAB interface registers:

- CAB Address register is set to the value of the CAB address to be read or written.
- CAB Control register is written with parameters that control the behavior for CAB access.
- CAB Data register, when accessed, initiates a CAB access and determines its type (read or write). If the CAB Data register is written, then the CAB access will be a write access. Likewise reading the CAB Data register will result in a CAB read access.
- Status register is read to determine, for polled access, whether read data is ready (rd_rdy).

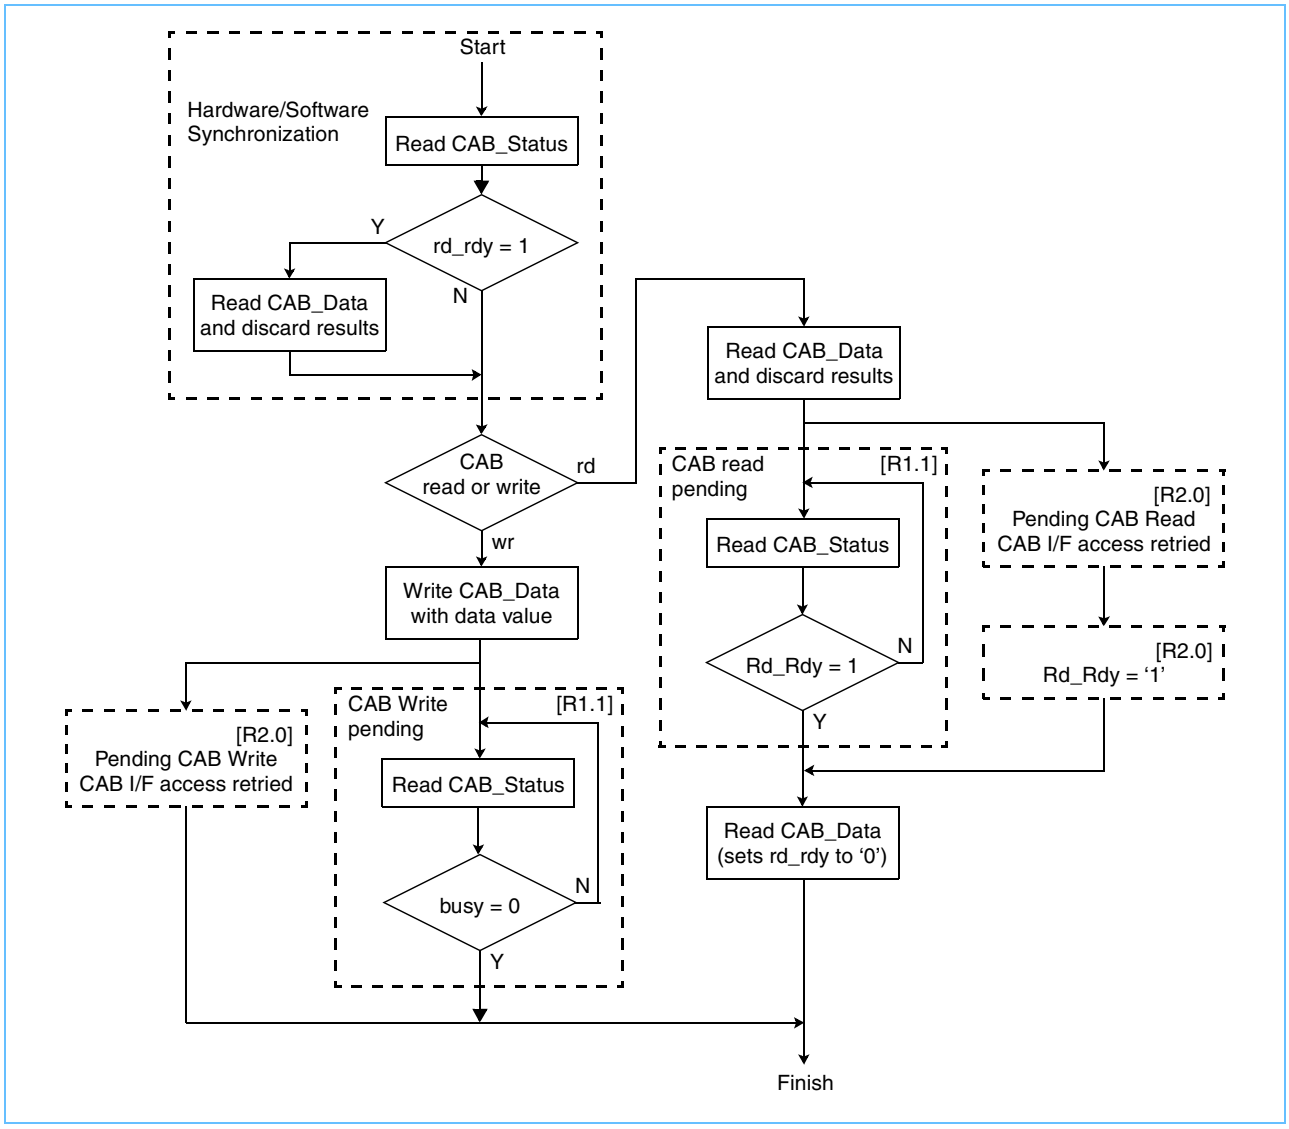
The CAB Control register (w/$\overline{p}$) controls the two modes of PLB protocol for CAB access:

- Wait access, w/$\overline{p}$ = '1', causes the CAB Interface macro to insert wait states on the PLB until the CAB access is complete. Software need not read the CAB Status register to determine completion.
- CAB access in polled mode requires software to follow the protocol defined in *Figure 10-2: Polled Access Flow Diagram* on page 375. Behavior for CAB accesses not following this protocol is undefined and may result in adverse effects. Polled access, w/$\overline{p}$ = '0' requires software to read the CAB Status register to synchronize software with the hardware when performing a CAB transaction. A CAB read transaction requires at least two read accesses to the CAB_Data register. An additional read access of the CAB_Data register may be required if the software is not synchronized with the hardware. Software synchronization is determined initially by reading the CAB_Status register. The software is not synchronized when the rd_rdy status bit is set to '1'. Synchronization is achieved by reading the CAB_Data register and discarding the result.

  A subsequent read of the CAB Data register initiates a CAB read access from the CAB address contained in the CAB Address register. The data returned as a result of this read of the CAB_Data register is stale data and is discarded by software. Software must then perform a final read of the CAB_Data register to acquire the data accessed on the CAB and return the CAB Interface to its starting state (rd_rdy = '0').

  NP4GS3A (R1.1) requires reading of the CAB_Status register as a part of the CAB access protocol. NP4GS3B (R2.0) causes subsequent accesses to the CAB interface registers to be retried until a pending CAB access is complete. Prolonged locking of the CAB by the EPC will result in extended retries by the PowerPC subsystem or PCI Host. Under these conditions, system hardware and software design must be able to tolerate long periods of retry.

Figure 10-2. Polled Access Flow Diagram



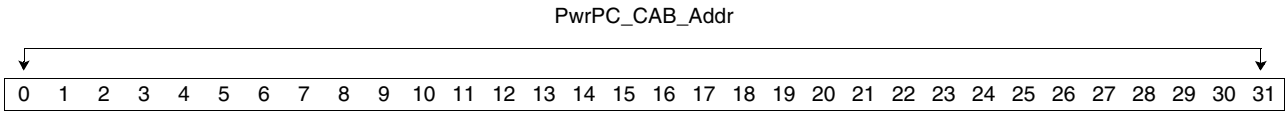
h

10.7.1 PowerPC CAB Address (PwrPC_CAB_Addr) Register

The PowerPC CAB Address register is accessible from the PLB and supplies a CAB address value for PowerPC subsystem access to NP4GS3 structures via the CAB Interface.

Access Type Read/Write

Base Address (PLB) x‘7800 0000’



Field Name	Bit(s)	Reset	Description
PwrPC_CAB_Addr	0:31	x’0000 0000’	CAB address value for PowerPC subsystem access to NP4GS3 structures via the CAB Interface.

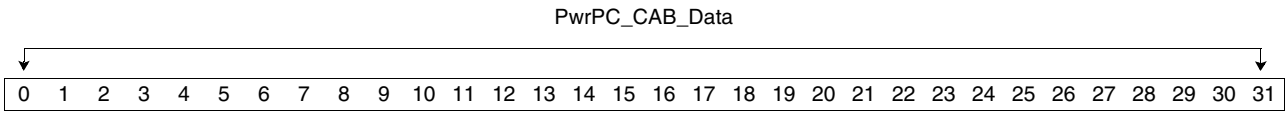
10.7.2 PowerPC CAB Data (PwrPC_CAB_Data) Register

The PowerPC CAB Data register is accessible from the PLB and contains the value of CAB data written or read when the PowerPC subsystem accesses NP4GS3 structures via the CAB Interface. Writing to the PwrPC_CAB_Data register has the side effect of initiating a write access on the CAB. The data value written to the PwrPC_CAB_Data register is written to the CAB address contained in the PwrPC_CAB_Addr register.

When the PwrPC_CAB_Cntl register has been configured with its w/$\overline{p}$ bit set to ‘1’ or if its w/$\overline{p}$ bit is set to ‘0’ and the rd_rdy bit of the PwrPC_CAB_Status register is set to ‘0’, a read of the PwrPC_CAB_Data register has the side effect of initiating a corresponding read access on the CAB. At the end of the CAB read access, the data value indicated by the PwrPC_CAB_Addr register is stored in the PwrPC_CAB_Data register and the rd_rdy bit of the PwrPC_CAB_Status register is set to '1. When the w/$\overline{p}$ bit set to ‘1’, the data value is also returned to the PLB. Otherwise, a subsequent read access of the PwrPC_CAB_Data register is required to retrieve the data value.

Access Type Read/Write

Base Address (PLB) x‘7800 0008’



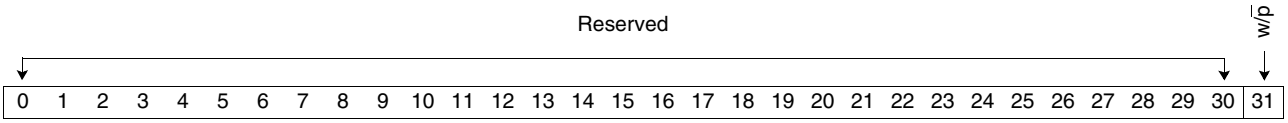
Field Name	Bit(s)	Reset	Description
PwrPC_CAB_Data	0:31	x’0000 0000’	CAB data written or read when the PowerPC subsystem accesses NP4GS3 structures via the CAB Interface.

10.7.3 PowerPC CAB Control (PwrPC_CAB_Cntl) Register

The PowerPC CAB Control register is accessible from the PLB and controls the CAB access protocol used by the PowerPC subsystem. The bit in this register indicates whether the wait or polled protocol is used when the PowerPC subsystem accesses CAB connected structures within the NP4GS3.

Access Type Read/Write

Base Address (PLB) x‘7800 0010’



Field Name	Bit(s)	Reset	Description
Reserved	0:30		Reserved
w/$\overline{p}$	31	0	Wait or polled access control value 0 PowerPC subsystem polls the PwrPC_CAB_Status register to determine when access is complete 1 CAB Interface macro inserts wait states on the PLB until the CAB access is complete

10.7.4 PowerPC CAB Status (PwrPC_CAB_Status) Register

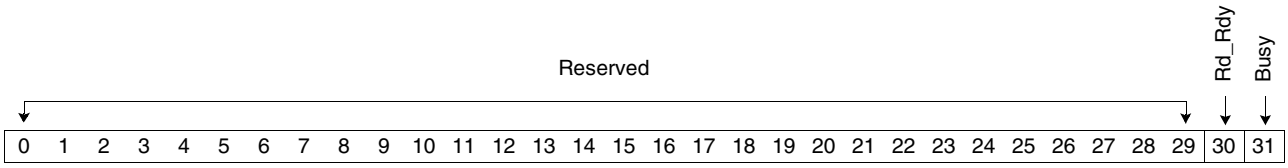
The PowerPC CAB Status register is accessible from the PLB and monitors the status of PowerPC CAB accesses. Bits within this register indicate the status of PowerPC subsystem accesses of CAB connected structures within the NP4GS3.

NP4GS3A (R1.1)

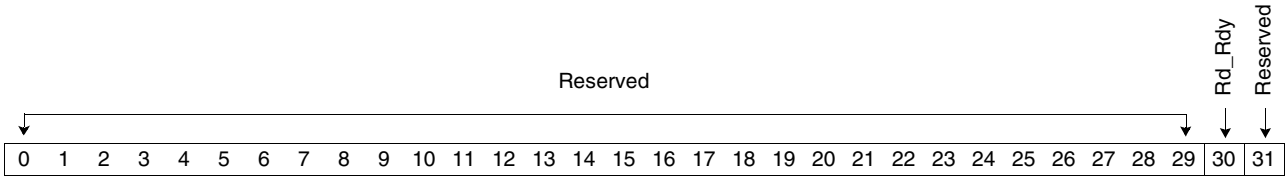
Access Type Read

Base Address (PLB) x‘7800 0018’

NP4GS3B (R2.0)



NP4GS3A (R1.1)



Field Name	Bit(s)	Description
Reserved	0:29	Reserved
Rd_Rdy	30	Read Data Ready indicator (used for polled access mode w/$\overline{p}$ = ‘0’ only) 0 No data in CAB Data register, a new CAB access can begin. 1 Data from a CAB read access is waiting in the CAB Data register
Busy	31	Busy indicator value. 0 CAB access is not pending. Set when CAB access is complete. 1 CAB access is pending. Set when CAB access (read or write) is initiated.

NP4GS3B (R2.0)

Field Name	Bit(s)	Description
Reserved	0:29	Reserved
Rd_Rdy	30	Read Data Ready indicator (used for polled access mode w/$\overline{p}$ = ‘0’ only) 0 No data in CAB Data register, a new CAB access can begin. 1 Data from a CAB read access is waiting in the CAB Data register
Reserved	31	Reserved

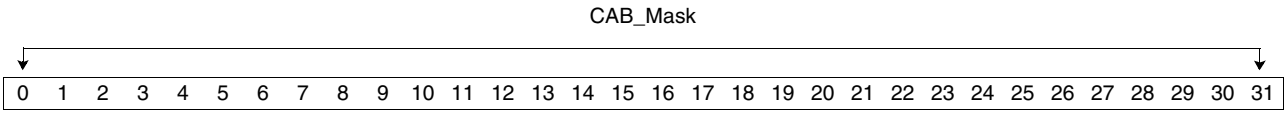
10.7.5 PowerPC CAB Mask (PwrPC_CAB_Mask) Register [NP4GS3B (R2.0) Only]

The PowerPC CAB Mask (PwrPC_CAB_Mask) register is accessible from the PLB and supplies a mask value used in conjunction with a write-under-mask CAB access. Each '1' bit of the mask indicates which bits of the CAB register will be updated. The corresponding bit value of the PwrPC_CAB_WUM_Data register is used to update the CAB register. All other bits of the CAB register will remain unaltered.

Hardware Reset x'0000 0000'

PLB Address x'7800 0020' PowerPC CAB Mask register

Access Type Read/Write



Field Name	Bit(s)	Description
PwrPC_CAB_Mask	0:31	CAB mask value for PowerPC subsystem access to IBM Network Processor structures via the CAB Interface. Each '1' bit of the mask indicates which bits of the CAB register will be updated.

10.7.6 PowerPC CAB Write Under Mask Data (PwrPC_CAB_WUM_Data) [NP4GS3B (R2.0) Only]

The PowerPC CAB Data (PwrPC_CAB_WUM_Data) register is accessible from the PLB and contains the value of CAB data written when the PowerPC subsystem accesses IBM Network Processor structures via the CAB Interface using the write-under-mask function. Writing to the PwrPC_CAB_WUM_Data register has the side effect of initiating a write-under-mask access on the CAB. The data value written to the PwrPC_CAB_WUM_Data register is combined with the contents of the PwrPC_CAB_Mask register and the contents of the CAB register indicated by the PwrPC_CAB_Addr register. For each bit location in which the value of the PwrPC_CAB_Mask register is '1', the corresponding bit of the CAB register is updated with the contents of the PwrPC_CAB_WUM_Data register. All other bits of the CAB register remain unaltered.

The bits of this register are shared with the PwrPC_CAB_Data register. Writing to this register will alter the contents of the PwrPC_CAB_Data register.

Hardware Reset x'0000 0000'

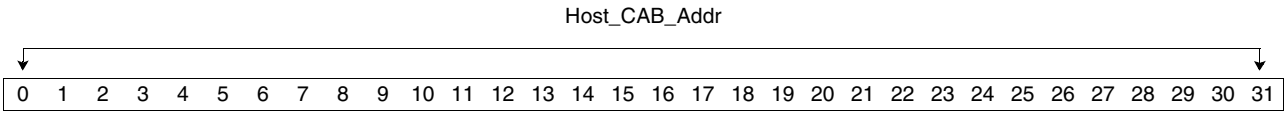
10.7.7 PCI Host CAB Address (Host_CAB_Addr) Register

The PCI Host CAB Address register is accessible from the PLB and supplies a CAB address value for PCI Host access to NP4GS3 structures via the CAB Interface.

Access Type Read/Write

Base Address (PLB) x‘7800 8000’



Field Name	Bit(s)	Reset	Description
Host_CAB_Addr	0:31	x’0000 0000’	CAB address value for PCI Host access to NP4GS3 structures via the CAB Interface.

10.7.8 PCI Host CAB Data (Host_CAB_Data) Register

The PCI Host CAB Data register is accessible from the PLB and contains the value of CAB data written or read when the PCI Host accesses NP4GS3 structures via the CAB Interface. Writing to the Host_CAB_Data register has the side effect of initiating a write access on the CAB. The data value written to the Host_CAB_Data register is written to the CAB address contained in the Host_CAB_Addr register.

When the Host_CAB_Cntl register has been configured with its w/$\overline{p}$ bit set to ‘1’ or if its w/$\overline{p}$ bit is set to ‘0’ and the Rd_Rdy bit of the Host_CAB_Status register is set to ‘0’, a read of the Host_CAB_Data register has the side effect of initiating a corresponding read access on the CAB. At the end of the CAB read access, the data value indicated by the Host_CAB_Addr register is stored in the Host_CAB_Data register and the rd_rdy bit of the Host_CAB_Status register is set to '1. When the w/$\overline{p}$ bit set to ‘1’, the data value is also returned to the PLB. Otherwise, a subsequent read access of the Host_CAB_Data register is required to retrieve the data value.

10.8 Mailbox Communications and DRAM Interface Macro

The Mailbox and DRAM Interface macro consists of two major portions. The first portion is a set of facilities for constructing and signalling messages between the various processors. A set of message resource registers allocates buffers for message construction, a set of message address registers accomplishes message signalling, and a set of doorbell registers accomplishes other inter-processor signalling. The second portion is hardware that interfaces the NP4GS3's DRAM controller to the PLB. The DRAM Interface maps a range of PLB addresses into DRAM addresses. DRAM connected via this interface stores PowerPC instructions, message data, and other data associated with the PowerPC subsystem.

The Mailbox and DRAM Interface macro also provides redirection of boot code. This function is used in system implementations in which the NP4GS3 does not boot from PCI memory. In these cases, hardware decodes the first PowerPC instruction fetch and supplies up to eight instructions from registers internal to the Mailbox and DRAM Interface. These registers are accessible via the CAB and are loaded by software prior to releasing the PowerPC processor's reset (PwrPC_Reset). Code stored in these registers redirects execution to locations in the DRAM.

10.8.1 Mailbox Communications Between PCI Host and PowerPC Subsystem

Communication between the PCI Host and the PowerPC subsystem is accomplished through PCI Host to PowerPC subsystem (H2P) and PowerPC subsystem to PCI Host (P2H) interrupts. The P2H interrupt is implemented by asserting the NP4GS3's INTA# signal output. PCI interrupts are level sensitive and are asynchronous with the PCI_Clk signal. The existing PCI Macro's INTA# signal is supplemented with other interrupt generation outside of the PCI Macro. Using the PCI Macro, the PowerPC subsystem can send an interrupt to the PCI Host by writing to the PCI/PLB Macro's PCI Interrupt Control/Status register. This interrupt signal is recorded in the PCI Interrupt Status register. Doorbell and Message register operations are additional sources of PCI interrupts. The PCI Macro can interrupt the PowerPC subsystem by setting bit 13 of the PCI Macro's Bridge Options 2 register. This interrupt signal is applied to the PowerPC Universal Interrupt Controller (UIC).

Communications between the PCI Host and the PowerPC subsystem use message buffers in PCI address space. Software running in the PCI Host manages these buffers. For communications from the PowerPC subsystem to the PCI Host, the starting address of empty message buffers are stored in the P2H Message Resource (P2H_Msg_Resource) register. This register is accompanied by a P2H_Bufr_Valid status flag, located in the Msg_Status register, that indicates whether or not the P2H_Msg_Resource register contains a valid buffer address.

The PCI Host writes the P2H_Msg_Resource register with the PCI address of an empty message buffer and the valid indicator flag is set. The PowerPC subsystem reads the flag value when a message buffer is required and then reads the valid message buffer address value from the P2H_Msg_Resource register. Reading the P2H_Msg_Resource register resets the valid indicator bit. By polling this indicator bit, the PCI Host knows when to replenish the P2H_Msg_Resource register with a new buffer address value.

Having acquired a message buffer, the PowerPC subsystem composes a message in the buffer and writes the buffer's starting address value into the P2H_Msg_Addr register. This write also sets the PCI_Interr_Status register's P2H_msg bit. A PCI interrupt is generated when the corresponding bit of the PCI_Interr_Ena register is set. The PCI Host reads the P2H_Msg_Addr register to find and process the message. The read clears the interrupt condition.

For communication from the PCI Host to the PowerPC, messages are composed in buffers in the PCI address space. Each message is then signalled to the PowerPC subsystem by writing its starting PCI address value into the H2P_Msg_Addr register. Writing this register sets the H2P_Msg_Interr to the

PowerPC UIC and sets the H2P_Msg_Busy bit of the Msg_Status register. An interrupt is generated when enabled by the UIC. The PowerPC subsystem reads the H2P_Msg_Addr register at one address location to find and process the message and, due to the read, the interrupt condition is cleared. A subsequent read of the H2P_Msg Addr register at another address location will reset the H2P_Msg_Busy bit of the Msg_Status register. This second read signals the PCI Host that the PowerPC subsystem has finished processing the data buffer, allowing it to be reused.

The P2H_Msg_Addr register is written by the PowerPC subsystem and read by the PCI Host processor. Whenever the PowerPC subsystem writes the P2H_Msg_Addr register, a bit in the PCI Interrupt Status register is set to ‘1’ and is independent of the value written. The PCI Interrupt Status register indicates the source of the PCI Interrupt. The PCI Interrupt Status register bit is reset to '0' when the PCI Host processor reads the P2H_Msg_Addr register. Software discipline controls the setting of the interrupt by the PowerPC subsystem and the resetting of the interrupt by the PCI Host (only the PowerPC subsystem writes this register and only the PCI Host reads this register).

The Doorbell register is written and read by either the PowerPC subsystem or the PCIHost processor. The value recorded in this register depends upon the data value to be written, the current contents of the register, and whether the PowerPC subsystem or the PCI Host processor is writing the register.

When written by the PowerPC subsystem, each bit of the register’s current contents is compared with the corresponding data bit to be written. If the value of the data bit is ‘1’, then the corresponding Doorbell register is set to ‘1’. Otherwise it remains unchanged (‘0’ or ‘1’). This effect is referred to as set-under-mask (SUM).

When written by the PCI Host processor, each bit of the register’s current contents is compared with the corresponding data bit to be written. If the value of the data bit is ‘1’, then the corresponding Doorbell register bit is reset to ‘0’. Otherwise, it remains unchanged (‘0’ or ‘1’). This effect is referred to as reset-under-mask (RUM). If one or more of the bits in the Doorbell register are ‘1’, then a signal is generated and stored in the PCI Interrupt Status register.

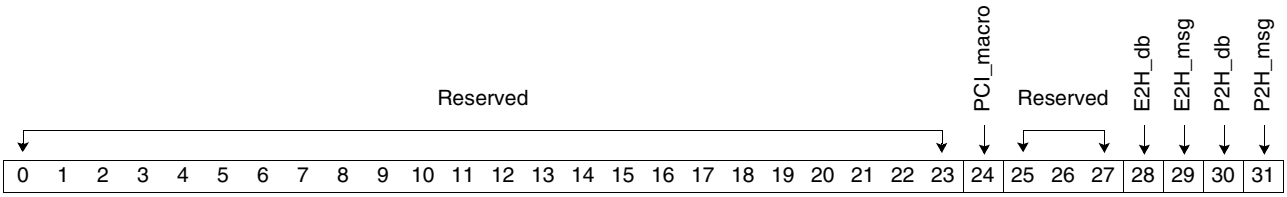
Any of the signals recorded as ‘1’ in the PCI Interrupt Status register activates the INTA# signal if the corresponding condition is enabled in the NP4GS3’s PCI Interrupt Enable register. The PCI Host processor reads the PCI Interrupt Status register to determine the interrupt source.

10.8.2 PCI Interrupt Status (PCI_Interr_Status) Register

The PCI Interrupt Status register is accessible from the PLB and records the source of the PCI interrupts generated by the NP4GS3. This register's bits are set by hardware and are read by PCI Host software. When the interrupt source is cleared, the corresponding bit of the PCI_Interr_Status register is also cleared.

Access Type Read Only

Base Address (PLB) x'7801 0000'



Field Name	Bit(s)	Reset	Description
Reserved	0:23		Reserved
PCI_macro	24	0	PCI interrupt from macro indicator. A PCI interrupt is asserted by the PLB to PCI macro when bit 0 of the macro's PCIICS register is set by software to a value of '1'. See the *IBM PowerPC 405GP Embedded Processor User's Manual* for details. 0 Interrupt absent 1 Interrupt present
Reserved	25:27		Reserved
E2H_db	28	0	EPC to PCI Host doorbell indicator. 0 PCI interrupt from E2H_Doorbell register absent 1 PCI interrupt from E2H_Doorbell register present

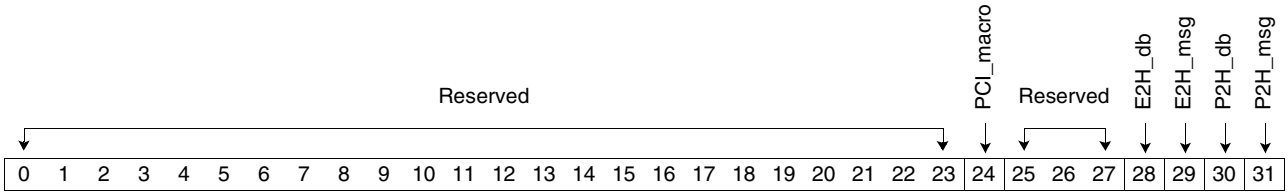
P2H_db	30	0	PowerPC subsystem to PCI Host doorbell indicator. 0 PCI interrupt from P2H_Doorbell register absent 1 PCI interrupt from P2H_Doorbell register present
P2H_msg	31	0	PowerPC subsystem to PCI Host message indicator. 0 PCI interrupt from P2H_Message register absent 1 PCI interrupt from P2H_Message register present

10.8.3 PCI Interrupt Enable (PCI_Interr_Ena) Register

The PCI Interrupt Enable register is accessible from the PLB and enables PCI interrupts from sources within the NP4GS3.

Access Type Read/Write

Base Address (PLB) x‘7801 0008’



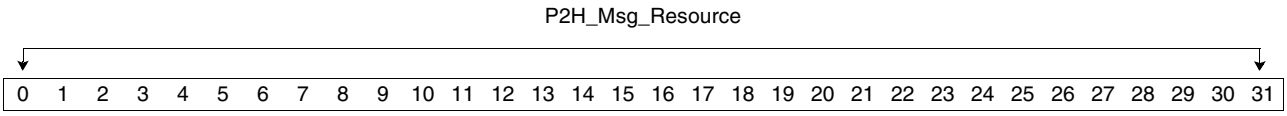
Field Name	Bit(s)	Reset	Description
Reserved	0:23		Reserved
PCI_macro	24	0	PCI macro interrupt - controls the assertion of a PCI interrupt from the PCI macro. A PCI interrupt is asserted by the PLB to PCI macro when bit 0 of the macro's PCIICS register is set by software to a value of '1'. See the *IBM PowerPC 405GP Embedded Processor User's Manual* for details. 0 Interrupt disabled 1 Interrupt enabled
Reserved	25:27		Reserved
E2H_db	28	0	EPC to PCI Host doorbell interrupt - controls the assertion of a PCI interrupt from the E2H_Doorbell register. 0 Interrupt disabled 1 Interrupt enabled
E2H_msg	29	0	EPC to PCI Host message interrupt - controls the assertion of a PCI interrupt from the E2H_Message register. 0 Interrupt disabled 1 Interrupt enabled
P2H_db	30	0	PowerPC subsystem to PCI Host doorbell interrupt - controls the assertion of a PCI interrupt from the P2H_Doorbell register. 0 Interrupt disabled 1 Interrupt enabled
P2H_msg	31	0	PowerPC subsystem to PCI Host message interrupt - controls the assertion of a PCI interrupt from the P2H_Message register. 0 Interrupt disabled 1 Interrupt enabled

10.8.4 PowerPC Subsystem to PCI Host Message Resource (P2H_Msg_Resource) Register

The PowerPC Subsystem to PCI Host Message Resource register is accessible from the PLB. The PowerPC subsystem uses this register to obtain message buffers in PCI address space for messages the PowerPC subsystem sends to the PCI Host processor. The PCI Host writes the starting PCI address value of a message buffer into the P2H_Msg_Resource register. Writing to this register sets the P2H_Bufr_Valid flag found in the Message Status Register (see *10.8.23 Message Status (Msg_Status) Register* on page 409) and reading the P2H_Msg_Resource register clears this flag.

Access Type Read/Write

Base Address (PLB) x‘7801 0010’



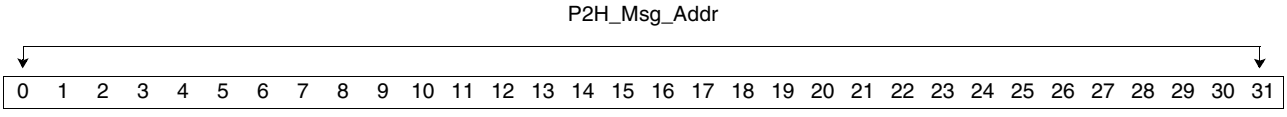
Field Name	Bit(s)	Reset	Description
P2H_Msg_Resource	0:31	x’0000 0000’	PowerPC subsystem to PCI Host Message Resource value, written with the PCI starting address of a message buffer. Writing this register sets to 1 the P2H_Bufr_Valid flag found in the Message Status Register (see *10.8.23 Message Status (Msg_Status) Register* on page 409). Reading this register sets to 0 the P2H_Bufr_Valid flag.

10.8.5 PowerPC Subsystem to Host Message Address (P2H_Msg_Addr) Register

The PowerPC Subsystem to PCI Host Message Address register is accessible from the PLB and is used by the PowerPC subsystem to send messages to the PCI Host processor. The value written into this register is the PCI address at which the message begins. Writing to this register sets the P2H_msg bit of the PCI_Interr_Status register. When the corresponding bit of the PCI_Interr_Ena register is set to ‘1’, the INTA# signal of the PCI bus is activated. The P2H_msg bit of the PCI_Interr_Status register is reset when the interrupt service routine reads the P2H_Msg_Addr register.

Access Type Read/Write

Base Address (PLB) x‘7801 0018’

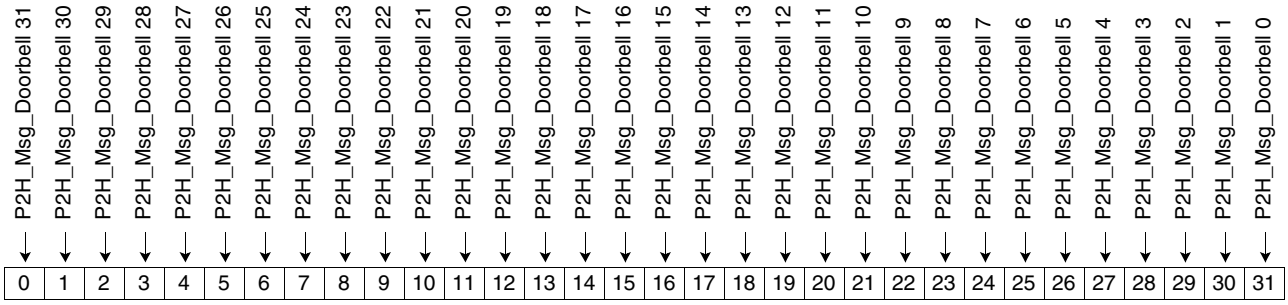


Field Name	Bit(s)	Reset	Description
P2H_Msg_Addr	0:31	x’0000 0000’	PowerPC subsystem to PCI Host Message address value, indicates the PCI starting address of a message.

10.8.6 PowerPC Subsystem to Host Doorbell (P2H_Doorbell) Register

The PowerPC Subsystem to PCI Host Doorbell register is accessible from the PLB and is used by the PowerPC subsystem to signal interrupts to the PCI Host processor. The PowerPC subsystem has read and SUM write access to this register. The data contains the mask used to access this register. When bits of this register are set to '1' and the corresponding bit of the PCI_Interr_Ena register is set to '1', the INTA# signal of the PCI bus is activated. The PCI Host processor reads this register to determine which of the doorbells have been activated. The PCI Host processor has read and RUM write access to this register using a different PLB address value.

Access Type	Power PC	x'7801 0020'
	Host	x'7801 0028'
Base Address (PLB)	Power PC	Read/Set-Under-Mask
	Host	Read/Reset-Under-Mask

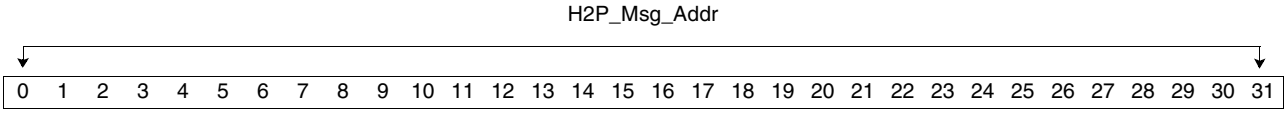


Field Name	Bit(s)	Reset	Description
P2H_Msg_Doorbell 31	0	0	PowerPC subsystem to PCI host doorbell - indicates which of the 32 possible doorbells have been activated. 0 Not activated 1 Activated
P2H_Msg_Doorbell 30:1	1:30	0 for all	
P2H_Msg_Doorbell 0	31	0	

10.8.7 Host to PowerPC Subsystem Message Address (H2P_Msg_Addr) Register

The PCI Host to PowerPC Subsystem Message Address register is accessible from the PLB and is used by the PCI Host to send messages to the PowerPC subsystem's processor. The value written into this register is a message's PCI starting address. Writing to this register activates the H2P_Msg_Interr input to the PowerPC UIC. When this interrupt is enabled, an interrupt to the PowerPC subsystem is generated. Reading this register resets the H2P_Msg_Interr input to the UIC. Reading this register at the alternate PLB address resets the Message Status register's H2P_Msg_Busy bit (see *10.8.23 Message Status (Msg_Status) Register* on page 409).

Access Type	Alternate	Read (Additional actions occur when reading this register using this address. Please see above description for details.)
	Primary	Read/Write
Base Address (PLB)	Alternate	x'7801 0050'
	Primary	x'7801 0060'

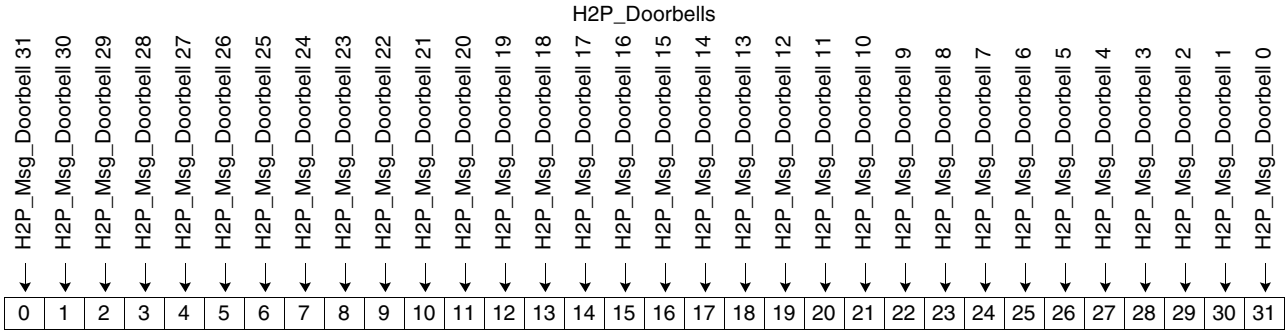


Field Name	Bit(s)	Reset	Description
H2P_Msg_Addr	0:31	x'0000 0000'	The value is a message's PCI starting address.

10.8.8 Host to PowerPC Subsystem Doorbell (H2P_Doorbell) Register

The PCI Host to PowerPC Subsystem Doorbell (H2P_Doorbell) register is accessible from the PLB and is used by the PCI Host processor to signal interrupts to the PowerPC subsystem. The PCI Host processor has read and SUM write access to this register. The data contains the mask used to access this register. When any of this register's bits are set to '1', an interrupt signal of the PowerPC UIC is activated. The PowerPC subsystem reads this register to determine which of the doorbells have been activated. The PowerPC subsystem has read and RUM write access to this register using a different PLB address value.

Access Type	Host	Read/Set-Under-Mask Write
	PowerPC	Read/Reset-Under-Mask Write
Base Address (PLB)	Host	x'7801 0030'
	PowerPC	x'7801 0038'



Field Name	PLB Bit(s)	Reset	Description
H2P_Msg_Doorbell 31	0	0	PCI Host to PowerPC subsystem doorbell - indicates which of the 32 possible doorbells have been activated. 0 Not activated 1 Activated
H2P_Msg_Doorbell 30:1	1:30	0 for all	
H2P_Msg_Doorbell 0	31	0	

10.8.9 Mailbox Communications Between PowerPC Subsystem and EPC

Communication between the PowerPC subsystem and the EPC is accomplished by writing message data into buffers in the PowerPC DRAM (D6) and signalling the destination processor with an interrupt. The PowerPC software manages message data buffers for PowerPC Subsystem to EPC (P2E) messages and EPC to PowerPC Subsystem (E2P) messages.

Message data buffers are allocated to the EPC by writing the buffers' starting address into the E2P_Msg_Resource register. Writing to this register sets the E2P_Bufr_Valid flag in the Msg_Status register. This flag indicates to the EPC that the buffer is valid and can be used by the EPC. The EPC reads the E2P_Bufr_Valid value when a message buffer is required. The EPC then reads the E2P_Msg_Resource register via the CAB Interface to obtain the address of the message buffer and the E2P_Bufr_Valid indicator bit is reset. By polling this indicator bit, the PowerPC subsystem's processor knows when to replenish the E2P_Msg_Resource register with a new buffer address value. Having acquired a message data buffer, the EPC composes a message in the buffer and writes the buffer's starting address value into the E2P_Msg_Addr register. Writing to this register generates an interrupt signal to the PowerPC UIC. The PowerPC subsystem reads this register to find and process the message and, due to the read, the interrupt condition is cleared.

There is no need for a P2E_Msg_Resource register because the PowerPC software manages the message data buffers The PowerPC subsystem composes a message in one of the data buffers and writes the starting address of the buffer into the P2E_Msg_Addr register. Writing to this register produces an interrupt to the EPC and sets the P2E_Msg_Busy bit of the Msg_Status register. As long as this flag is set, the EPC is processing the message buffer. The EPC reads the P2E_Msg_Addr register to locate the buffer in the PowerPC DRAM. The EPC resets the P2E_Msg_Busy bit by reading the P2E_Msg_Address register at an alternate CAB address when message processing is complete. The PowerPC subsystem will poll the busy flag to determine when the buffer can be reused.

10.8.10 EPC to PowerPC Subsystem Resource (E2P_Msg_Resource) Register

The PowerPC subsystem accesses the EPC to PowerPC Subsystem Message Resource register from the PLB while the EPC accesses this register from its CAB Interface. The EPC uses this register to obtain message buffers in the PowerPC DRAM address space for messages it sends to the PowerPC processor. The PowerPC processor writes the starting DRAM address value of a message buffer. Writing to this register sets the E2P_Bufr_Valid flag in the Msg_Status register (see *10.8.23 Message Status (Msg_Status) Register* on page 409). Reading the E2P_Msg_Resource register from the CAB resets this flag.

Access Type	CAB	Read (See above description for additional actions that occur during a read of this register using this address.)
	PLB	Read/Write (See above description for additional actions that occur during a read of this register using this address.)

PLB View

Field Name	Bit(s)	Reset	Description
E2P_Msg_Resource	0:31	x’0000 0000’	EPC to PowerPC Subsystem Message Resource - written with the PowerPC DRAM starting address of a message buffer.

10.8.11 EPC to PowerPC Subsystem Message Address (E2P_Msg_Addr) Register

The PowerPC subsystem accesses the EPC to PowerPC Subsystem Message Address register from the PLB while the EPC accesses this register from its CAB Interface. The EPC uses this register to send messages to the PowerPC processor. The value written into this register is the PowerPC DRAM address at which the message begins. Writing to this register sets E2P_Msg_Interr input to the PowerPC UIC. When the UIC is configured to enable this input, an interrupt signal to the PowerPC processor is activated. Reading the E2P_Msg_Addr register via the PLB address resets the E2P_Msg_Interr input to the PowerPC UIC.

10.8.12 EPC to PowerPC Subsystem Doorbell (E2P_Doorbell) Register

The PowerPC subsystem accesses the EPC to PowerPC Subsystem Doorbell register from the PLB while the EPC accesses this register from the CAB Interface. The EPC uses this register to signal interrupts to the PowerPC subsystem. The EPC has read and SUM write access to this register using a CAB address value. The data contains the mask used to access this register. When any of this register's bits are set to '1' an interrupt signal to the PowerPC UIC is activated. The PowerPC subsystem reads this register to determine which of the doorbells have been activated.The PowerPC subsystem has read and RUM write access to this register using a PLB address value.

Access Type	CAB	Read/Set-Under-Mask Write
	PLB	Read/Reset-Under-Mask Write
Base Address	CAB	x'3801 0040'
	PLB	x'7801 0058'

E2P_Msg_Doorbell 0	31	0	

10.8.13 EPC Interrupt Vector Register

The EPC contains an Interrupt Vector 2 register which is accessible from the CAB Interface. This register records the source of EPC interrupts generated by the NP4GS3. This register's bits are set by hardware and are read by EPC software to determine the source of interrupts.

10.8.14 EPC Interrupt Mask Register

The EPC contains a Interrupt Mask 2 register which is accessible from the CAB Interface. This register enables EPC interrupts from sources within the NP4GS3.

10.8.15 PowerPC Subsystem to EPC Message Address (P2E_Msg_Addr) Register

The PowerPC subsystem accesses the PowerPC Subsystem to EPC Message Address register from the PLB, while the EPC accesses this register from the CAB Interface. This register is used by the PowerPC subsystem to send messages to the EPC. The value written into this register is the PowerPC DRAM address at which the message begins. Writing to this register sets the P2E_Msg_Interr signal to the EPC and the P2E_Msg_Busy bit of the Msg_Status register. Reading the P2E_Msg_Addr register from the CAB will reset the P2E_Msg_Interr signal to the EPC. Reading the P2E_Msg_Addr from an alternate CAB address will reset the P2E_Msg_Busy bit of the Msg_Status register (see *10.8.23 Message Status (Msg_Status) Register* on page 409).

10.8.17 Mailbox Communications Between PCI Host and EPC

Communication between the PCI Host processor and the EPC is accomplished by writing message data into buffers in the PowerPC DRAM and signalling the destination processor with an interrupt. The PCI Host processor software manages message data buffers for PCI Host processor to EPC (H2E) messages and EPC to PCI Host processor (E2H) messages.

Message data buffers are allocated to the EPC by writing the buffers' starting address into the E2H_Msg_Resource register. Writing this register sets the E2H_Bufr_Valid flag in the Msg_Status register. This flag indicates to the EPC that the buffer is valid and can be used by the EPC. The EPC reads the E2H_Bufr_Valid value when a message buffer is required. The EPC then reads the E2H_Msg_Resource register via the CAB Interface and the E2P_Bufr_Valid indicator bit is reset. By polling this indicator bit, the PCI Host processor knows when to replenish the E2H_Msg_Resource register with a new buffer address value. Having acquired a message data buffer, the EPC will compose a message in the buffer and write the buffer's starting address value into the E2H_Msg_Addr register. Writing to this register generates an interrupt to the PCI Host processor. The PCI Host processor reads this register to find and process the message. Reading this register clears the interrupt condition.

Since the PCI Host processor software manages the message data buffers, there is no need for an H2E_Msg_Resource register. The PCI Host processor composes a message in one of the data buffers and writes the starting address of the buffer into the H2E_Msg_Addr register. Writing to this register produces an interrupt input signal to the EPC and sets the H2E_Msg_Busy bit of the Msg_Status register. As long as this flag is set, the EPC is processing the message buffer. The EPC reads the H2E_Msg_Addr register to locate the buffer in the PowerPC DRAM and reset the interrupt input signal to the EPC. The EPC resets the H2E_Msg_Busy bit by reading the P2E_Msg_Addr register from an alternate CAB address when message processing is complete. The PowerPC subsystem will poll the H2E_Msg_Busy bit to determine when the buffer can be reused.

10.8.18 EPC to PCI Host Resource (E2H_Msg_Resource) Register

The PCI Host processor accesses the EPC to PCI Host Message Resource register from the PLB while the EPC accesses this register from its CAB Interface. This EPC uses this register to obtain message buffers in the PowerPC DRAM address space for messages it sends to the PCI Host processor. The PCI Host processor writes the starting DRAM address value of a message buffer into the E2P_Msg_Resource register. Writing to this register sets the E2H_Bufr_Valid flag found in the Message Status register (see *10.8.23 Message Status (Msg_Status) Register* on page 409). Reading the E2H_Msg_Resource register from the CAB resets this flag.

Access Type	CAB	Read (Additional actions occur when reading this register using this address. Please see above description for details.)
	PLB	Read/Write

When reading this register via the CAB, the E2H_Bufr_Valid flag found in the Message Status Register (see *10.8.23 Message Status (Msg_Status) Register* on page 409) is set to 0.

PLB View

Field Name	Bit(s)	Reset	Description
E2H_Msg_Resource	0:31	x’0000 0000’	EPC to PCI Host Message Resource - written with the PowerPC DRAM starting address of a message buffer. When writing this register, the E2H_Bufr_Valid flag is set to 1.

10.8.19 EPC to PCI Host Message Address (E2H_Msg_Addr) Register

The PCI Host Processor accesses the EPC to PCI Host Message Address register from the PLB while the EPC accesses this register from its CAB Interface. The EPC uses this register to send messages to the PCI Host processor. The value written into this register is the PowerPC DRAM address at which the message begins. Writing to this register sets the E2H_msg bit of the PCI_Interr_Status register. When the corresponding bit of the PCI_Interr_Ena register is set to '1', an interrupt signal to the PCI Host processor is activated. Reading the E2H_Msg_Addr register from the PLB resets the E2H_msg bit of the PCI_Interr_Status register.

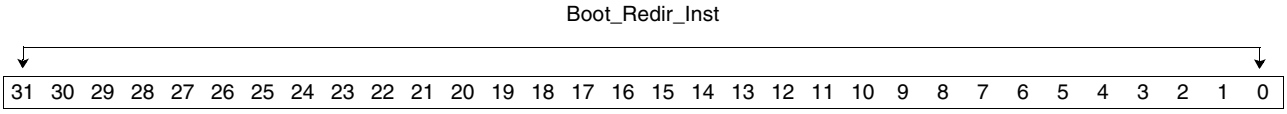
10.8.24 PowerPC Boot Redirection Instruction Registers (Boot_Redir_Inst)

In system implementations in which the embedded PowerPC subsystem boots from the D6 DRAM, the Mailbox and DRAM Interface macro performs PowerPC boot address redirection. Under these conditions, the hardware provides instructions that redirect the boot sequence to a location in the PowerPC DRAM. Storage for eight instructions is provided by the Boot_Redir_Inst registers.

The PowerPC Boot Redirection Instruction (Boot_Redir_Inst) registers are accessed from the CAB Interface. These registers provide capacity for eight instructions for PLB addresses x'FFFF FFE0' - x'FFFF FFFC' These instructions redirect the PowerPC subsystem to boot from a location in the PowerPC DRAM and are configured before the PPC_Reset is cleared.

Access Type Read/Write

Base Address x'3800 0110' - x'3800 0117'



Field Name	Bit(s)	Reset	Description
Boot_Redir_Inst	31:0	x'0000 0000'	PowerPC boot redirection instruction address values contains instructions used by the PowerPC subsystem to redirect the boot sequence to a location in D6 DRAM. 10.8.25 PowerPC Machine Check (PwrPC_Mach_Chk) Register

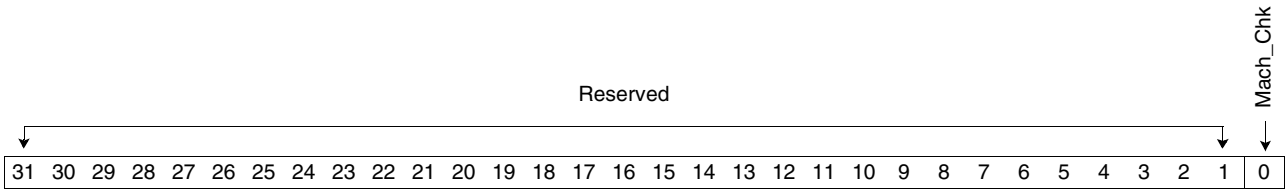
This register is accessible on the CAB and indicates the status of the machine check output of the PowerPC processor core.

Access Type Read

Base Address (CAB) x‘3800 0210’



Field Name	Bit(s)	Reset	Description
Reserved	31:1		Reserved
Mach_Chk	0	0	PowerPC machine check indication. 0 No machine check has occurred 1 A machine check has occurred

10.8.26 Parity Error Status and Reporting

When reading the PowerPC subsystem memory, any parity errors encountered are recorded and actions are taken. PowerPC subsystem memory parity errors are indicated for each double word returned on the PLB regardless of the object size read. For this reason, parity must be initialized for every double word in each memory region used. Furthermore, for PowerPC processor code regions, correct parity must be initialized for each cache line in the region. Parity will be set correctly when the memory is written. Therefore, for code regions, this parity initialization is accomplished automatically when the code is loaded. Likewise, this initialization is performed if a diagnostic is performed on the memory that writes to every location. In all other cases, this parity initialization must be performed for each region of memory used prior to use.

Since even bytes and odd bytes of the PowerPC subsystem memory are stored in physically distinct modules, error statistics are collected on an odd and even byte basis. This information may prove useful in isolation of a failing part. The word address value of the most recent parity error is stored in the Slave Error Address Register (SEAR). In addition, bits of the Slave Error Status Register (SESR) indicate which PLB masters have experienced parity errors in reading the PowerPC subsystem memory. This status information is indicated by odd and even byte for each of the three PLB masters (Instruction Cache Unit, Data Cache Unit, and PCI/PLB macro).

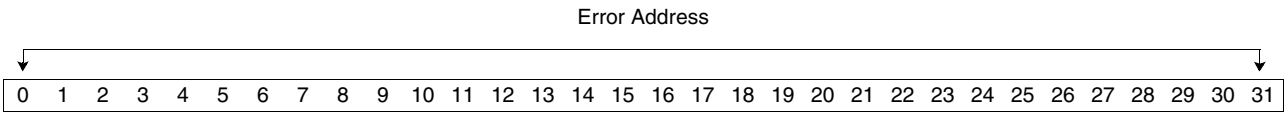
Bits of the SESR are used to generate an interrupt input to the UIC. If any of these bits are set to b'1' then the parity error interrupt input to the UIC is set to b'1'. When the UIC is configured to enable this interrupt input, an interrupt signal is generated to the PPC405 Core for processing. As a part of the interrupt service routine, the SESR must be read to clear the source of the interrupt.

10.8.27 Slave Error Address Register (SEAR)

The Slave Error Address Register records the word address value of the last occurrence of a parity error encountered by the DRAM Interface slave unit. This address value will isolate the location of the parity error to within a word.

Access Type Read

Base Address (PLB) x'7801 00B8'



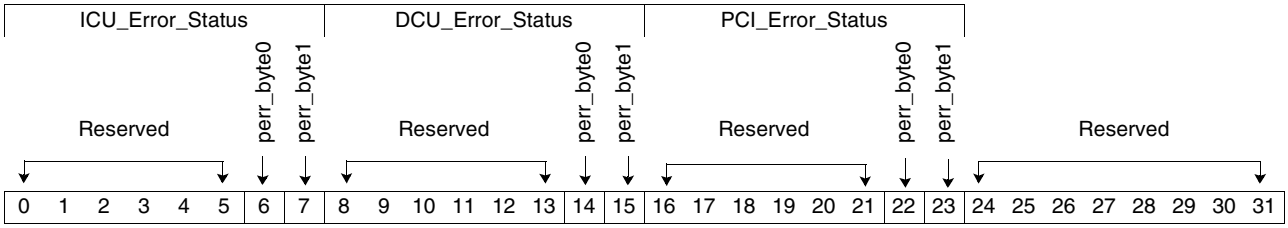
Field Name	Bit(s)	Reset	Description
Error Address	0:31	x'0000 0000'	Last PLB word address value that resulted in a parity error when using the DRAM Interface slave unit.

10.8.28 Slave Error Status Register (SESR)

The Slave Error Status Register contains status information that indicates which masters have encountered parity errors in reading from the DRAM and whether these errors occurred in a byte with an even (Perr_Byte0) or an odd (Perr_Byte1) address value. The PowerPC subsystem has three PLB masters: the Instruction Cache Unit (ICU), the Data Cache Unit (DCU), and the PCI macro. The contents of this register are reset to x'0000 0000' when read.

Access Type Read and Reset

Base Address (PLB) x'7801 00C0'



Field Name	Bit(s)	Reset	Description
Reserved	0:5		Reserved
Perr_Byte0	6	0	Byte 0 parity error indication - whether or not the Instruction Cache Unit PLB master encountered a parity error since the register was last read. 0 No parity error encountered 1 Parity error encountered

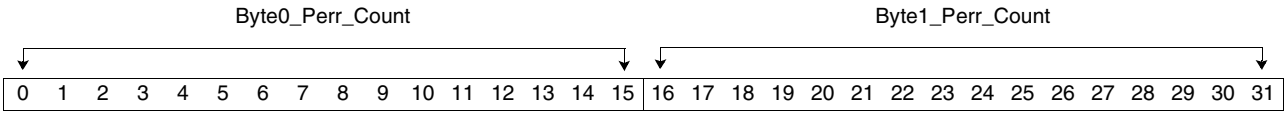
Perr_Byte1	15	0	Byte 1 parity error indication - whether or not the Data Cache Unit PLB master encountered a parity error since the register was last read. 0 No parity error encountered 1 Parity error encountered
Reserved	16:21		Reserved
Perr_Byte0	22	0	Byte 0 parity error indication - whether or not the PCI Macro PLB master encountered a parity error since the register was last read. 0 No parity error encountered 1 Parity error encountered
Perr_Byte1	23	0	Byte 1 parity error indication - whether or not the PCI Macro PLB master encountered a parity error since the register was last read. 0 No parity error encountered 1 Parity error encountered
Reserved	24:31		Reserved

10.8.29 Parity Error Counter (Perr_Count) Register

The Parity Error Counter register contains two 16-bit counter values. These counters accumulate the total number of parity errors for even and odd byte addresses since the last time the chip was reset. These counters roll over to zero when their maximum value is reached (65535).

Access Type Read

Base Address (PLB) x‘7801 00C8’



Field Name	Bit(s)	Reset	Description
Byte0_Perr_Count	0:15	x’0000’	Count of byte 0 parity errors encountered when reading DRAM from DRAM Interface slave unit.
Byte1_Perr_Count	16:31	x’0000’	Count of byte 1parity errors encountered when reading DRAM from DRAM Interface slave unit.

10.9 System Start-Up and Initialization

10.9.1 NP4GS3 Resets

Table 10-1. Reset Domains

Reset Domain	Applies
PowerPC Core	Applies only to the PPC405 processor core and is used to control its start-up during system initialization
Network Function	Applies to all other functions in the NP4GS3

A general reset is performed whenever the NP4GS3's Reset input pin is activated. A general reset includes the PowerPC Core, and the NP4GS3 Network Function reset domains. The PowerPC Core and the NP4GS3 Network Function reset domains are also controlled by separate configuration registers, PowerPC_Reset and Soft_Reset, respectively. Each of these registers are accessible via the NP4GS3's CAB Interface. A general reset sets the PowerPC_Reset to '1' (activated), but the Soft_Reset will be set to '0' (deactivated).

When the general reset is deactivated, the PowerPC Core remains in reset and the PowerPC Macros and the NP4GS3 Network Function are in an idle condition with state machines active and control structures uninitialized. The NP4GS3 Network Function will be functional once EPC picocode has been loaded and control structures are initialized. The EPC is activated automatically when loading boot picocode from the SPM interface or by setting the BD_Override bit to '1' in the Boot Override register (see *13.13.4 Boot Override Register (Boot_Override)* on page 463). The PowerPC Core is activated by clearing the bit of the PowerPC_Reset register.

The PowerPC Core and the NP4GS3 Network Function domains are separately reset and activated by setting and clearing their respective reset registers. Setting the control bit in the Soft_Reset register causes the Network Function to be momentarily reset while the PowerPC subsystem is held in reset. The PowerPC_Reset is also activated whenever the Watch Dog timer of the PowerPC Core expires for a second time and Watch Dog Reset Enable (WD_Reset_Ena) is set to '1'. When enabled, the second expiration of the Watch Dog timer results in a pulse on the SERR# signal of the PCI Bus. The TCR [WRC] of the PowerPC Core is set to '10' to generate a chip reset request on the second expiration of the Watch Dog timer.

The PowerPC Core can be reset from the RISCWatch debugger environment. A Core reset performed from RISCWatch resets the PPC405 Core, but does not set the PowerPC_Reset control register. This allows a momentary reset of the PowerPC Core and does not require a release of the PowerPC Core by clearing the PowerPC_Reset control register. The PowerPC Core is also reset and the PowerPC_Reset control register is set when a 'chip reset' command is performed from RISCWatch and the Watch Dog Reset Enable is set to '1'. This resets the PowerPC Core and holds it in reset until the PowerPC_Reset register is cleared.

10.9.2 Systems Initialized by External PCI Host Processors

System implementations with control function centralized in a PCI Host processor are initialized primarily by an external PCI Host processor. These systems do not use the SPM Interface or its associated flash memory to boot the EPC and DASL picocode (Boot_Picocode = '1'). The host processor (Boot_PPC = '0') loads code for the PowerPC processor and the EPC and DASL picoprocessors.

The general sequence of the start-up and initialization is as follows:

1. The host processor boots and performs blade level configuration and testing while holding blade subsystems in reset.
2. The host processor releases each of the blade subsystems' reset signals in sequence.
3. Release of the general reset input pin of the NP4GS3 activates its state machines. The NP4GS3 is in an idle state with un-initialized structures and the PPC405 Core remains in reset and Host PCI Configuration is enabled.
4. The host system uses the PCI Configuration protocol to configure internal registers of the PCI Interface Macro. This configuration sets the base address values of the PCI Target Maps. The PCI Master Maps are disabled.
5. The host processor uses the appropriate PCI target address values to configure and initialize the NP4GS3's DRAM controllers via the CAB Interface.
6. The host processor uses the appropriate PCI target address values to load the PowerPC code into one of the NP4GS3's DRAMs. This code includes the branch code loaded into the Boot_Redir_Inst registers.
7. The host loads the picocode memories of the EPC and DASL. These memories are accessible via the CAB Interface macro. The addresses of the registers controlling this interface were mapped to PCI addresses in step 4.
8. The host processor starts the PPC405 Core by clearing the PowerPC_Reset configuration register. This register is accessed via the CAB Interface. The PowerPC subsystem starts by fetching the instruction at PLB address x'FFFF FFFC'. This address is decoded by hardware to provide an unconditional branch to instruction space in the PowerPC DRAM memory.
9. The host processor uses the CAB Interface to set the BD_Override bit to '1' in the Boot Override register (see *13.13.4 Boot Override Register (Boot_Override)* on page 463) to start the EPC code. This code controls the initialization of the NP4GS3 structures in preparation for network traffic. Alternatively, this initialization is performed by the host processor via the CAB Interface.
10. Communication ports are configured and enabled by either the host processor or the PPC405 Core.

10.9.3 Systems with PCI Host Processors and Initialized by PowerPC Subsystem

The PowerPC subsystem primarily controls start-up and initialization sequences of systems of this category. These systems do not use the SPM Interface or its associated flash memory for booting the EPC boot picocode (Boot_Picocode = '1'). The PowerPC subsystem boots from PCI address space (Boot_PPC = '1') and loads code for the PowerPC processor and the EPC and DASL picoprocessors.

The general sequence of the start-up and initialization is as follows:

1. The host processor boots and performs blade level configuration and testing while holding blade subsystems in reset.
2. The host processor releases each of the blade subsystems' reset signals in sequence.
3. Release of the general reset input pin of the NP4GS3 activates its state machines. The NP4GS3 is in an idle state with un-initialized structures and the PPC405 Core remains in reset and Host PCI Configuration is enabled.
4. The host system uses the PCI Configuration protocol to configure internal registers of the PCI Interface Macro. This configuration sets the base address values of the PCI Target Maps. The PCI Master Maps are disabled except for the PMM0 which maps PLB addresses x'FFFE 0000' through x'FFFF FFFF' to the same addresses in PCI address space.
5. The host processor starts the PPC405 Core by clearing the PowerPC_Reset configuration register. This register is accessed via the CAB Interface.
6. The PPC405 Core will boot from code residing in the PCI address space starting at address x'FFFF FFFC'.
7. The PPC405 Core processor configures and initializes the NP4GS3's DRAM controllers via the CAB Interface.
8. The PPC405 Core processor loads the PowerPC code, via the DRAM Interface Macro, into one of the NP4GS3's DRAMs.
9. The PPC405 Core processor loads the picocode for the EPC and DASL via the CAB Interface.
10. Using the CAB Interface, the host processor sets the BD_Override bit to '1' in the Boot Override register (see *13.13.4 Boot Override Register (Boot_Override)* on page 463) to start the EPC picocode. This picocode will control the initialization of the NP4GS3 structures in preparation for network traffic. Alternatively, this initialization is performed by the PPC405 Core processor via the CAB Interface.
11. Communication ports are configured and enabled by the PPC405 Core.

10.9.4 Systems Without PCI Host Processors and Initialized by PowerPC Subsystem

The EPC initially controls start-up and initialization sequences of systems of this category, but they are primarily controlled by the PowerPC subsystem. These systems use the SPM Interface and its associated flash memory for booting the EPC picocode (Boot_Picocode = '0'). The PowerPC subsystem boots from PCI address space (Boot_PPC = '1') and loads code for the PowerPC processor and the EPC and DASL picoprocessors.

The general sequence of the start-up and initialization is as follows:

1. Release of the general reset input pin of the NP4GS3 activates its state machines. The PCI Master Maps are disabled except for the PMM0 which maps PLB addresses x‘FFFE 0000’ through x‘FFFF FFFF’ to the same addresses in PCI address space. EPC boot picocode is loaded from the flash memory via the SPM Interface. The SPM Interface automatically starts the EPC and the PPC405 Core remains in reset.
2. EPC code executes diagnostic and initialization code which includes the initialization of the NP4GS3’s DRAM controllers.
3. The EPC starts the PPC405 Core by clearing the PowerPC_Reset configuration register. This register is accessed via the CAB Interface.
4. The PPC405 Core will boot from code residing in the PCI address space starting at address x‘FFFF FFFC’.
5. The PPC405 Core processor loads the PowerPC code via the DRAM Interface Macro into one of the NP4GS3’s DRAMs.
6. The PPC405 Core processor or the EPC loads the picocode for the DASL via the CAB Interface.
7. Communication ports are configured and enabled by the PPC405 Core.

10.9.5 Systems Without PCI Host or Delayed PCI Configuration and Initialized by EPC

The EPC controls start-up and initialization sequences of systems of this category. These systems use the SPM Interface and its associated flash memory for booting the EPC picocode (Boot_Picocode = '0'). Code for the PowerPC subsystem and the EPC are loaded by the SPM Interface and the EPC (Boot_PPC = '0'). Code for the PowerPC subsystem exists in the flash memory or is provided using Guided Traffic.

The general sequence of the start-up and initialization is as follows:

1. Release of the general reset input pin of the NP4GS3 activates its state machines. EPC picocode is loaded from the flash memory via the SPM Interface. The SPM Interface automatically starts the EPC. The PPC405 Core remains in reset and PCI Host Configuration is disabled.
2. EPC code executes diagnostic and initialization code, which includes the initialization of the NP4GS3's DRAM controllers.
3. The EPC loads the code for the PowerPC processor from the flash memory into the DRAM. This code includes the branch code loaded into the Boot_Redir_Inst registers. Alternatively, this code is loaded using Guided Traffic. Guided Traffic flows once the communications port connecting the source has been enabled (see step 6).
4. The EPC starts the PPC405 Core by clearing the PowerPC_Reset configuration register. This register is accessed via the CAB Interface.
5. The PPC405 Core will boot from code residing in the PLB address space starting at address x'FFFF FFFC'. This address is decoded by hardware to provide an unconditional branch to instruction space in the PowerPC DRAM memory.
6. If desired, the PPC405 Core can change the contents of the PCI Configuration Header registers and enable PCI Host Configuration.
7. Communication ports are configured and enabled by the PPC405 Core or, alternatively, by the EPC.

11. Reset and Initialization

This section provides, by example, a method for initializing the NP4GS3. It is not intended to be exhaustive in scope, since there are many configurations and environments where the NP4GS3 may be applied. The external Serial Parallel Manager (SPM) Field Programmable Gate Array (FPGA) mentioned in this chapter is a component of the Network Processor Evaluation Kit and is not sold separately.

11.1 Overview

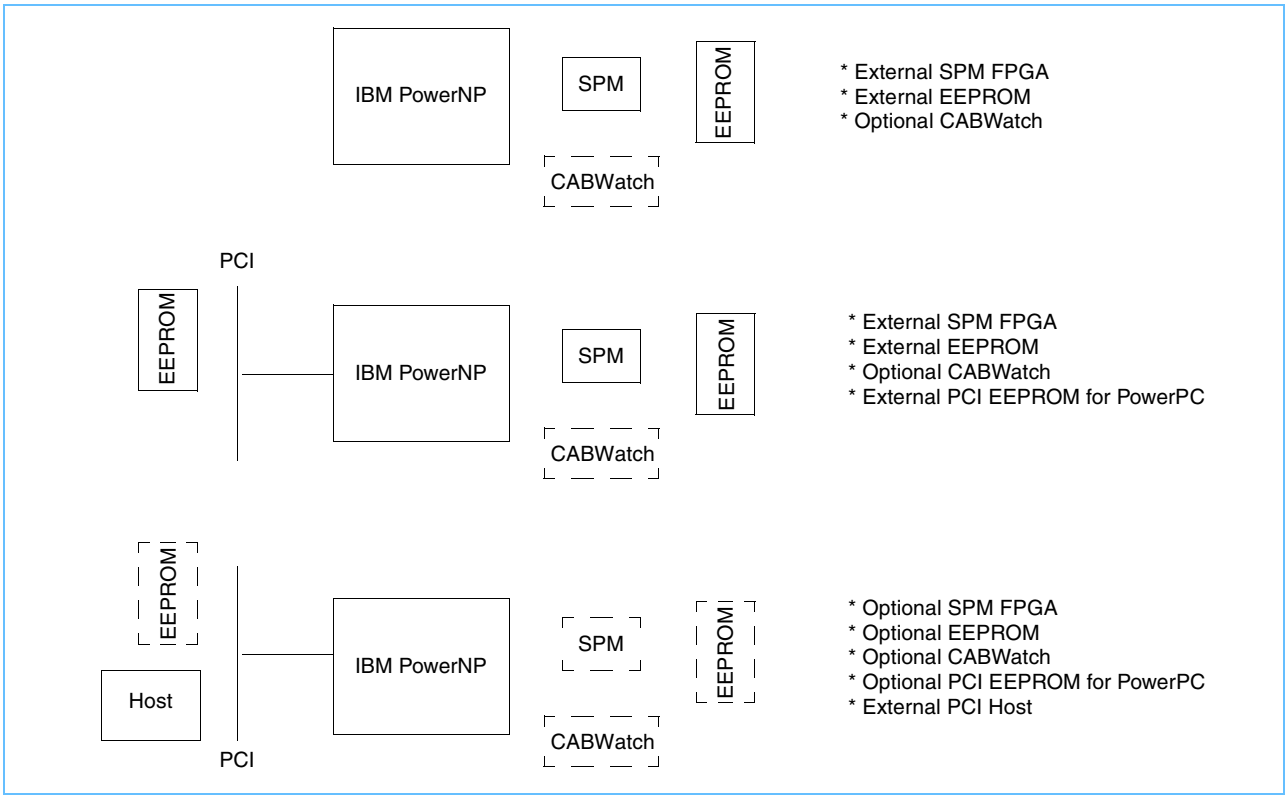
The NP4GS3 supports a variety of system and adapter configurations. In order to support a particular environment, the network processor must be initialized with parameters that match that environment's system or adapter requirements. The sequence of reset and initialization is shown in *Table 11-1*.

Table 11-1. Reset and Initialization Sequence

Step	Action	Notes
1	Set I/Os	Device I/Os set to match adapter requirements
2	Reset	Must be held in reset for minimum of 1 μs
3	Boot	Several Boot options
4	Setup 1	Low Level Hardware setup
5	Diagnostics 1	Memory and Register Diagnostics
6	Setup 2	Basic Hardware setup
7	Hardware Initialization	Hardware self-initialization of various data structures
8	Diagnostics 2	Data Flow Diagnostics
9	Operational	Everything ready for first Guided Frame
10	Configure	Functional Configuration
11	Initialization Complete	Everything ready for first Data Frame

Some system environments do not require all of the steps and some require that certain steps be performed differently. The NP4GS3 supports the system environments shown in *Figure 11-1* for Reset and Initialization.

Figure 11-1. System Environments



The following sections describe each step in the Reset and Initialization sequence and the various ways to accomplish each step.

11.2 Step 1: Set I/Os

Several NP4GS3 I/Os must be set to appropriate values to operate correctly. Most of these I/Os will be set to a fixed value at the card level, but some will be set to the appropriate value based on system parameters. The following table lists all configurable I/Os that must be set prior to initial reset.

Table 11-2. Set I/Os Checklist

I/O	Values	Notes
Testmode(1:0)	See *Table 2-30: Miscellaneous Pins* on page 77 for the encoding of these I/O	Adapter may require mechanism to set test mode I/Os in order to force various test scenarios.
Boot_Picocode	See *Table 2-30: Miscellaneous Pins* on page 77 for the encoding of this I/O	Controls which interface loads the internal EPC instruction memory and boots the Guided Frame Handler thread.
Boot_PPC	See *Table 2-30: Miscellaneous Pins* on page 77 for the encoding of this I/O	Controls from where the internal PPC fetches its initial boot code.
PCI_Speed	See *Table 2-26: PCI Pins* on page 72 for the encoding of this I/O	Controls the speed of the PCI bus
Switch_BNA	See *Table 2-30: Miscellaneous Pins* on page 77 for the encoding of this I/O	Initial value for Primary switch interface
CPDetect_A	See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for the encoding of this I/O	Used to find a locally attached Control Point Function (CPF)
CPDetect_B	See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for the encoding of this I/O	Used to find a locally attached CPF
CPDetect_C	See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for the encoding of this I/O	Used to find a locally attached CPF
CPDetect_D	See *Table 2-15: PMM Interface Pin Multiplexing* on page 55 for the encoding of this I/O	Used to find a locally attached CPF
Spare_Tst_Rcvr(9:0)	See *Table 2-30: Miscellaneous Pins* on page 77 for the correct tie values for these I/O	Used during manufacturing testing

Additional configuration bits could be utilized by defining additional I/O on an external SPM FPGA as configuration inputs. If the user defines registers in the SPM CAB address space and a corresponding external SPM FPGA design, the NP4GS3 can read these SPM I/Os and make configuration adjustments based on their values (for example, the type of CP interface might be 100 Mb or 1 Gb). Custom boot picocode is required to take advantage of these additional features.

All clocks must be operating prior to issuing a reset to the NP4GS3. The Clock_Core, Switch Clock A, and Switch Clock B drive internal PLLs that must lock before the internal clock logic will release the Operational signal. The Clock125 and DMU_*(3) inputs, if applicable, should also be operating in order to properly reset the DMU interfaces. The PCI Clock (PCI_Clk) must be operating in order to properly reset the PCI Interface.

11.3 Step 2: Reset the NP4GS3

Once all configuration I/Os are set and the clocks are running, the NP4GS3 can be reset using the Blade_Reset signal. This signal must be held active for a minimum of 1 μs and then returned to its inactive state. Internal logic requires an additional 101 μs to allow the PLLs to lock and all internal logic to be reset. The PCI Bus must be idle during this interval to ensure proper initialization of the PCI bus state machine. At this point, the NP4GS3 is ready to be booted. In addition to the Blade_Reset signal, the NP4GS3 supports two other "soft" reset mechanisms: The Soft_Reset register allows the entire NP4GS3 to be reset (just like a Blade_Reset), and the PowerPC_Reset register allows the PowerPC core to be reset. A Blade_Reset or Soft_Reset causes the PowerPC_Reset register to activate and hold the PowerPC Core in reset until this register is cleared. Therefore, a Blade_Reset resets the entire NP4GS3 and holds the PowerPC Core in reset until it is released by the EPC or an external host using the PCI bus.

11.4 Step 3: Boot

11.4.1 Boot the Embedded Processor Complex (EPC)

Booting the NP4GS3's EPC involves loading the internal picocode instruction space and turning over control of execution to the GFH thread. The GFH thread executes the loaded picocode and completes the appropriate steps in the bringup process. The NP4GS3 supports four ways to load the internal picocode instruction space: through the SPM Interface Logic, through the PCI bus from an external host, through the embedded PowerPC, or through CABWatch. When using the last three methods, once the picocode instruction space is loaded, the BD_Override bit must be set to '1' in the Boot Override Register (see *13.13.4 Boot Override Register (Boot_Override)* on page 463), which causes the GFH thread to start the code stored at address '0'.

11.4.2 Boot the PowerPC

There are two steps in the process of booting the NP4GS3's embedded PowerPC. First, using the Boot_PPC I/O, the PowerPC support logic must be configured to boot the PowerPC from either the external D6 DRAM or the PCI bus. Second, the PowerPC must be released to execute the appropriate boot code. The PowerPC boot code can be mapped either into PCI address space or into the NP4GS3's external D6 DRAM, depending on the setting of the Boot_PPC I/O.

If an external Host processor is used on the PCI bus, it should use the PCI configuration protocol to set the NP4GS3's PCI Target Maps for access into the network processor's internal address space.

If the Boot_PPC I/O chooses the PCI bus, the internal PLB bus addresses x'FFFE 0000' through x'FFFF FFFF' are mapped to PCI address space. Once the PowerPC_Reset register is cleared (by either the EPC or by an external host across the PCI bus), the PowerPC will fetch and execute the boot code from across the PCI bus.

If the Boot_PPC I/O chooses the external D6 DRAM, the D6 DRAM must be written with the appropriate boot code and the Boot_Redir_Inst registers must be written to point to the code in the D6 DRAM before the PowerPC_Reset register is released. The internal logic maps the PowerPC's boot addresses of x'FFFF FFE0' through x'FFFF FFFC' to the Boot_Redir_Inst registers and the remaining boot code is fetched from the external D6 DRAM. The D6 DRAM and the Boot_Redir_Inst registers can be written by either the EPC or an external host on the PCI bus. When everything is set up, use a CAB write to clear the PowerPC_Reset register to allow the PowerPC Core to execute the boot code.

11.4.3 Boot Summary

The EPC must be booted by first loading its picocode instructions (by either the SPM, an external PCI host, the Embedded PowerPC, or CABWatch) and then issuing the Boot Done signal (by the picocode loader). If the Embedded PowerPC is to be used, it must have its instruction space loaded (if D6 is used), then pointing the boot logic to the appropriate boot location (PCI or D6), and finally releasing the PowerPC_Reset register (by either the EPC, an external PCI host, or CABWatch). Once one or both systems are booted, the following steps can be performed by one or both processing complexes. (Some accesses to external memories can only be performed by the EPC complex.)

11.5 Step 4: Setup 1

Setup 1 is needed to set some low level hardware functions that enable the NP4GS3 to interface with its external DRAMs and to configure some internal registers that enable the execution of Step 5: diagnostics 1. Setup 1 should configure or check the following registers according to the system setup and usage:

Table 11-3. Setup 1 Checklist

Register	Fields	Notes
Memory Configuration Register	All	This register is set to match the populated external memories.
DRAM Parameter Register	All	This register is set to match the external DRAM's characteristics.
Thread Enable Register	All	This register enables the non-GFH threads. The GFH is always enabled.
Initialization Register	DRAM Cntl Start	This bit starts the DRAM interfaces.
Initialization Done Register	CM Init Done E_DS Init Done	These bits indicate that the DRAM initialization has completed.

11.6 Step 5: Diagnostics 1

Diagnostics 1 tests internal registers, internal memories, and external memories as required by the diagnostics program (read and write tests). This step comes before the hardware initialization step because several of these structures will be initialized by the hardware to contain functional data structures. By testing these structures first, the diagnostics program does not need to be concerned with corrupting the contents of these locations during hardware initialization. Care must be taken that the values written to the structures do not force an undesirable situation (such as soft resetting the device). However, most of these structures can be tested by the diagnostics program to ensure proper operation. *Table 11-4* lists some of the structures that could be tested by this step.

Table 11-4. Diagnostics 1 Checklist

Structure	Test	Notes
Phase Locked Loop Fail	Verify all PLLs locked	If any PLL fails, any further operation is questionable.
DPPU Processors	ALU, Scratch Memory, Internal Processor Registers	Test each thread.
Ingress Data Store	Read/Write	
Egress Data Store	Read/Write	
Control Store D0-D4	Read/Write	
Control Store D6	Read/Write	Coordinated with PowerPC code loading
Control Store H0-H1	Read/Write	
Counter Definition Table	Configure	Set up to test Counters.
Counter Memory	Read/Write/Add	
Policy Manager Memory	Read/Write	
Egress QCBs	Read/Write	
Egress RCB	Read/Write	
Egress Target Port Queues	Read/Write	
MCCA	Read/Write	
PMM Rx/Tx Counters	Read/Write	
PMM SA Tables	Read/Write	
Ingress BCB	Read/Write	
Ingress FCB	Read/Write	Not all fields are testable.
CIA Memory	Read/Write	
Ingress Flow Control Probability Memory	Read/Write	
Egress Flow Control Probability Memory	Read/Write	
DASL-A Picocode Memory	Read/Write	
DASL-B Picocode Memory	Read/Write	
Various Internal Configuration Registers	Read/Write	Not all fields will be testable. Care must be taken when changing certain control bits.

11.7 Step 6: Setup 2

Setup 2 is needed to set up the hardware for self-initialization and to configure the hardware structures for operational state. These configuration registers must be set to the desirable values based on the system design and usage:

Table 11-5. Setup 2 Checklist

Register	Fields	Notes
Master Grant Mode	All	
TB Mode	All	
Egress Reassembly Sequence Check	All	
Aborted Frame Reassembly Action Control	All	
Packing Control	All	
Ingress BCB_FQ Thresholds	All	
Egress SDM Stack Threshold	All	
Free Queue Extended Stack Maximum Size	All	
Egress FQ Thresholds	All	
FCB Free Queue Size Register (FCB_FQ_Max)	All	
DMU Configuration	All	DMU Configuration can be postponed until Step 10: Configure if DMU Init Start is also postponed. DMU for CPF must be done during Setup 2. If the DMU is configured, the appropriate external Physical Devices must also be configured. Note that external physical devices should be held in reset until the DMU configuration is completed.
Packet Over SONET Control	All	POS Configuration can be postponed until Step 10: Configure if DMU Init Start is also postponed.
Ethernet Encapsulation Type for Control	All	
Ethernet Encapsulation Type for Data	All	
DASL Picocode Memory	Both A and B	Written with appropriate DASL picocode
DASL Initialization and Configuration	Primary Set	DASL Init can be postponed until the Configure Step if DASL Start is also postponed and CPF is locally attached.
DASL Initialization and Configuration	DASL Wrap Mode	DASL Wrap Mode can be postponed until the Configure Step.
DASL Wrap	All	

11.8 Step 7: Hardware Initialization

Hardware Initialization allows the NP4GS3 to self-initialize several internal structures, thereby decreasing the overall time required to prepare the processor for operation. Several internal structures will be initialized with free lists, default values, or initial states in order to accept the first guided frames from the CPF. Once these data structures are initialized, the picocode should not modify them with further read/write diagnostics. To initiate the hardware self-initialization, the registers shown in *Table 11-6* need to be written.

Table 11-6. Hardware Initialization Checklist

Register	Fields	Notes
DASL Start	All	Only start the DASL interface after the Primary Set of DASL configuration bits have been configured.
DASL Initialization and Configuration	Alt_Ena	Only start the Alternate DASL after the Primary DASL has been started.
Initialization	DMU set	Only start each DMU after its associated DMU Configuration has been set.
Initialization	Functional Island	Starts all other islands' self-initialization.

11.9 Step 8: Diagnostics 2

Diagnostics 2 determines if the NP4GS3 is ready for operation and allows testing of data flow paths. The items listed in *Table 11-7* should be set up, checked, and/or tested.

Table 11-7. Diagnostic 2 Checklist

Register	Fields	Notes
Initialization Done	All started in Hardware Initialization Step	The code polls this register until a timeout occurs or all expected bits are set. DASL timeout = 20 ms E_EDS timeout = 15 ms
DASL Initialization and Configuration	Pri_Sync_Term	If Primary DASL was initialized and Sync Termination should occur from the network processor, this register should be set to cause IDLE cells to be sent.
DASL Initialization and Configuration	Alt_Sync_Term	If Alternate DASL was initialized and Sync Termination should occur from the network processor, this register should be set to cause IDLE cells to be sent.
LU Def Table	Read/Write Test	These structures can only be tested after Hardware Initialization.
SMT Compare Table	Read/Write Test	These structures can only be tested after Hardware Initialization.
Tree Search Free Queues	Read/Write Test	These structures can only be tested after Hardware Initialization. Not all fields are testable.
Port Configuration Table	All	Set to default values for Diagnostics 2
LU Def Table	All	Set to default values for Diagnostics 2
Ingress Target Port Data Storage Map	All	Set to default values for Diagnostics 2
Target Port Data Storage Map	All	Set to default values for Diagnostics 2
Build Frame on Egress Side		Lease twins and store test frame in Egress Data Store
Half Wrap		Wrap test frame from Egress to Ingress using Wrap DMU
Full Wrap		Wrap Ingress frame back to Egress side if DASL in wrap mode or DASL has been completely configured including Target Blade information.
External Wrap		If external Physical Devices are configured, full external wraps can be performed.
Tree Searches		To test the tree search logic, tree searches can be performed on a pre-built sample tree written to memory.

11.10 Step 9: Operational

After the Diagnostics 2 tests have finished, any previously written default values may need to be updated to allow this step to proceed. If all Diagnostics have passed, the Operational signal can be activated to indicate to an external CPF that the NP4GS3 is ready to receive Guided Frames. This signal is activated by writing the NP4GS3 Ready register which then activates the $\overline{\text{Operational}}$ I/O. If some portion of the diagnostics have not passed, the Ready register should not be written. This causes the CPF to timeout and realize the diagnostic failure. To determine what portion of the diagnostics have failed, the system designer must make provisions at the board or system level to record the status in a location that is accessible by the CPF. One method is to provide an I^2C interface to an external SPM FPGA which the CPF could access.

11.11 Step 10: Configure

After the Operational signal has been activated, the CPF can send Guided Frames to the NP4GS3 for functional configuration. Items that can be configured include:

Table 11-8. Configure Checklist (Page 1 of 2)

Register	Fields	Notes
DASL Initialization and Configuration	Primary Set	The Primary Set can be configured if postponed during the Setup 2 Step.
DASL Initialization and Configuration	DASL Wrap Mode	DASL Wrap Mode can be set if postponed during Setup 2 Step.
DASL Start	All	Primary DASL can be started if postponed during Setup 2 Step.
DASL Initialization and Configuration	Alt_Ena	The Alternate Set can be configured if postponed during the Setup 2 Step.
Initialization Done	P_DASL Init Done	This bit should be polled if started during the Configure Step.
Initialization Done	A_DASL Init Done	This bit should be polled if started during the Configure Step.
DASL Initialization and Configuration	Pri_Sync_Term	If Primary DASL was initialized and Sync Termination should occur from the Network Processor, this register should be set to cause IDLE cells to be sent.
DASL Initialization and Configuration	Alt_Sync_Term	If Alternate DASL was initialized and Sync Termination should occur from the Network Processor, this register should be set to cause IDLE cells to be sent.
DMU Configuration	All	Configure now if DMU Configuration was postponed during Setup 2 Step. If the DMU is configured, the appropriate external Physical Devices also must be configured. Note that external physical devices should be held in reset until the DMU configuration is completed.
Packet Over SONET Control	All	Configure now if POS Configuration was postponed during Setup 2 Step.
Functional Picocode	All	Functional Picocode should be loaded into the Instruction Memory.
Port Config Table	All	Functional values for the PCT should be set
LU Def Table	All	Functional values should be set.
CIA Memory	All	Functional values should be set.
Hardware Classifier E_Type	All	Functional values should be set.
Hardware Classifier SAP	All	Functional values should be set.
Hardware Classifier PPP_Type	All	Functional values should be set.
Interrupt Masks	All	Functional values should be set.
Timer Target	All	Functional values should be set.
Interrupt Target	All	Functional values should be set.
Address Bounds Check Control	All	Functional values should be set.
Static Table Entries	All	Any Static Table Entries should be loaded.
Ingress Target Port Data Storage Map	All	
My Target Blade Address	All	

Table 11-8. Configure Checklist (Page 2 of 2)

Register	Fields	Notes
Local Target Blade Vector	All	
Local MC Target Blade Vector	All	
Target Port Data Storage Map	All	
Egress QCBs	All	
QD Accuracy	All	
SA Address Array	All	
Counter Definition Table	All	
Counters	All	Any Counters used by Counter Manager must be Read/ Cleared.
Policy Manager Memory	All	Set up initial values for Policies.

11.12 Step 11: Initialization Complete

Once steps 1 through 10 are complete and all items on the checklists have been configured, the NP4GS3 is ready for data traffic. The Ports can be enabled (at the Physical Devices) and Switch Cells can start to flow.

12. Debug Facilities

12.1 Debugging Picoprocessors

The NP4GS3 provides several mechanisms to facilitate debugging of the picoprocessors.

12.1.1 Single Step

Each thread of the NP4GS3 can be enabled individually for single step instruction execution. Single step is defined as advancing the instruction address by one cycle and executing the instruction accordingly for enabled threads. Coprocessors are not affected by single step mode. Therefore, coprocessor operations that at “live” speed would take several cycles may seem to take only one cycle in single step mode.

There are two ways to enable a thread for single step operation. The first is to write the Single Step Enable Register. This register is a single-step bit mask for each thread and can be accessed through the Control Access Bus (CAB). The second is the Single Step Exception Register. This register is also a bit mask, one for each thread, but when set indicates which threads are to be placed into single step mode on a class3 interrupt . When a thread is in Single Step Mode, the thread can only be advanced by writing the Single Step Command register.

12.1.2 Break Points

The NP4GS3 supports one instruction break point that is shared by all of the threads. When a thread’s instruction address matches the break point address, a class3 level interrupt is generated. This causes all threads enabled in the Single Step Exception Register to enter single step mode. The break point address is configured in the Break Point Address Register.

12.1.3 CAB Accessible Registers

The scalar and array registers of the Core Language Processor (CLP) and of the DPPU coprocessors are accessible through the CAB for evaluation purposes. The CLP’s General Purpose registers, which are directly accessible with the CLP, are mapped to read only scalar registers on the Control Access Bus.

12.2 RISCWatch

The NP4GS3 supports RISCWatch through the JTAG interface.

RISCWatch is a hardware and software development tool for the embedded PowerPC. It provides processor control and source-level debugging features, including:

- On-chip debugging via IEEE 1149.1 (JTAG) interface
- Target monitor debugging
- Open-source real-time operating system-aware debugging
- Source-level and assembler debugging of C/C^{++} executables
- Real-time trace support via the RISCTrace feature for the PowerPC 400 Series
- Network support that enables customers to remotely debug the systems they are developing
- Supports industry standard Embedded ABI for PowerPC and XCOFF ABI
- Command-file support for automated test and command sequences
- Simple and reliable 16-pin interface to the system the customer is developing
- Ethernet to target JTAG interface hardware
- Multiple hosts supported
- Intuitive and easy-to-use windowed user interface

For more information, go to http://www-3.ibm.com/chips/techlib/techlib.nsf/products/RISCWatch_Debugger

.

13. Configuration

The IBM PowerNP NP4GS3 must be configured after internal diagnostics have run. Configuration is performed by a CPF that generates guided traffic to write configuration registers. These configuration registers are reset by the hardware to a minimal option set.

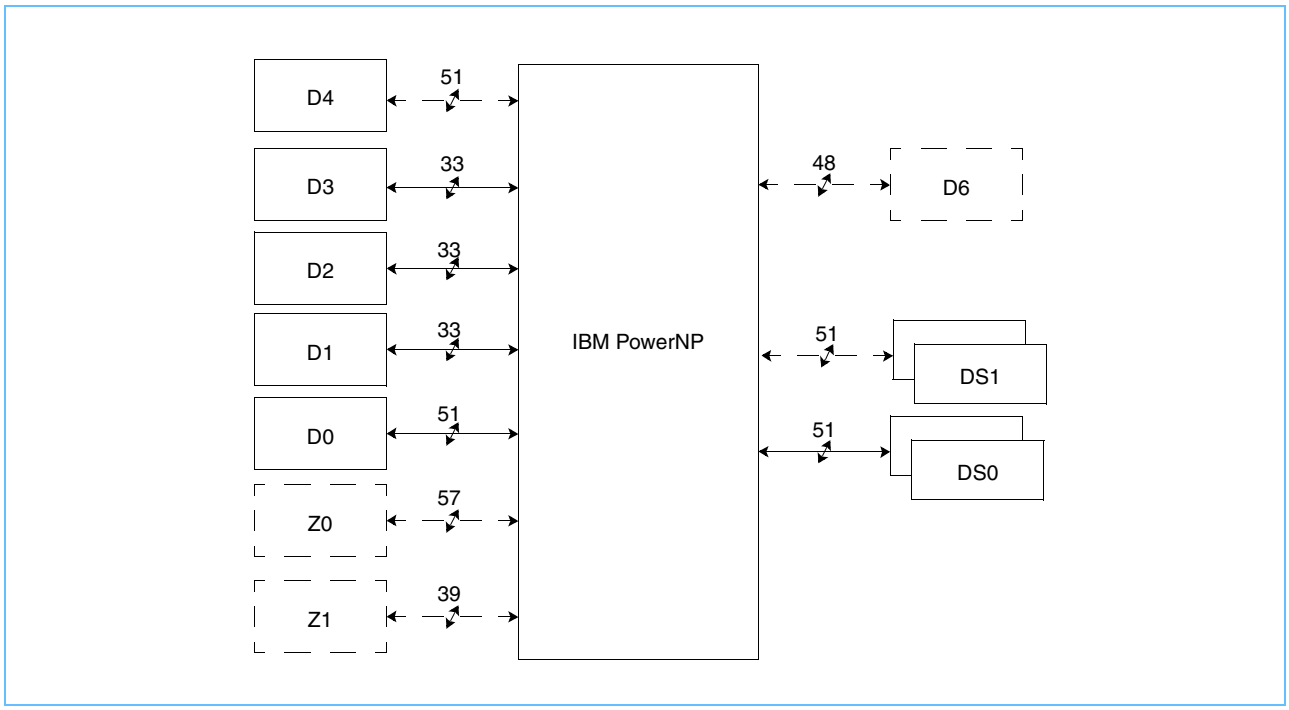
The following sections describe all configuration registers and their reset state. A base address and offset is provided.

13.1 Memory Configuration

The NP4GS3 is supported by a number of memory subsystems as shown in *Figure 13-1* below. These memory subsystems contain data buffers and controls used by the NP4GS3. The D0, D1, D2, D3, D4, DS_0, and DS_1 subsystems are required to operate the NP4GS3 base configuration. Memory subsystems Z0, Z1, and D6 are optional and provide additional functionality or capability when added to the required set of memory subsystems.

In its base configuration, the NP4GS3 does not perform enhanced scheduling, and has a limited look-up search capability. The enabling of memory subsystem interfaces is controlled by the contents of the memory configuration register. The bits in this register are set by hardware during reset to enable the base configuration.

Figure 13-1. NP4GS3 Memory Subsystems

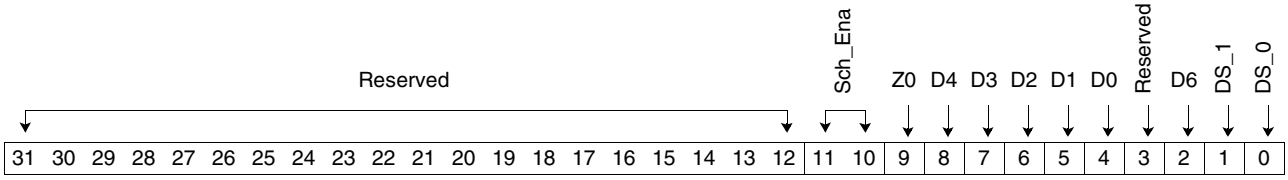


13.1.1 Memory Configuration Register (Memory_Config)

The memory configuration register enables or disables memory interfaces. It also enables the egress scheduler and the Z1 memory interface required by the egress scheduler to operate.

Access Type Read/Write

Base Address x'A000 0120'



Field Name	Bit(s)	Reset	Description
Reserved	31:12		Reserved
Sch_Ena	11:10	00	Scheduler Enabled control enables both egress scheduler and Z1 memory interface. 00 Scheduler disabled, Z1 interface disabled 01 Scheduler enabled, Z1 interface enabled 10 Scheduler disabled, Z1 interface enabled (NP4GS3B (R2.0) or later) 11 Reserved When enabling the scheduler, the target port queue count Qcnt_PQ must be zero for all ports. When setting this value to 0, the target port queue count Qcnt_PQ+FQ must be zero for all ports.
Z0	9	0	Z0 Memory Subsystem Interface Enabled control 1 Interface enabled 0 Interface disabled
D4	8	1	D4 Memory Subsystem Interface Enabled control 1 Interface enabled 0 Interface disabled
D3	7	1	D3 Memory Subsystem Interface Enabled control 1 Interface enabled 0 Interface disabled
D2	6	1	D2 Memory Subsystem Interface Enabled control 1 Interface enabled 0 Interface disabled
D1	5	1	D1 Memory Subsystem Interface Enabled control 1 Interface enabled 0 Interface disabled
D0	4	1	D0 Memory Subsystem Interface Enabled control 1 Interface enabled 0 Interface disabled
Reserved	3	0	Reserved
D6	2	0	D6 Memory Subsystem Interface Enabled control 1 Interface enabled 0 Interface disabled

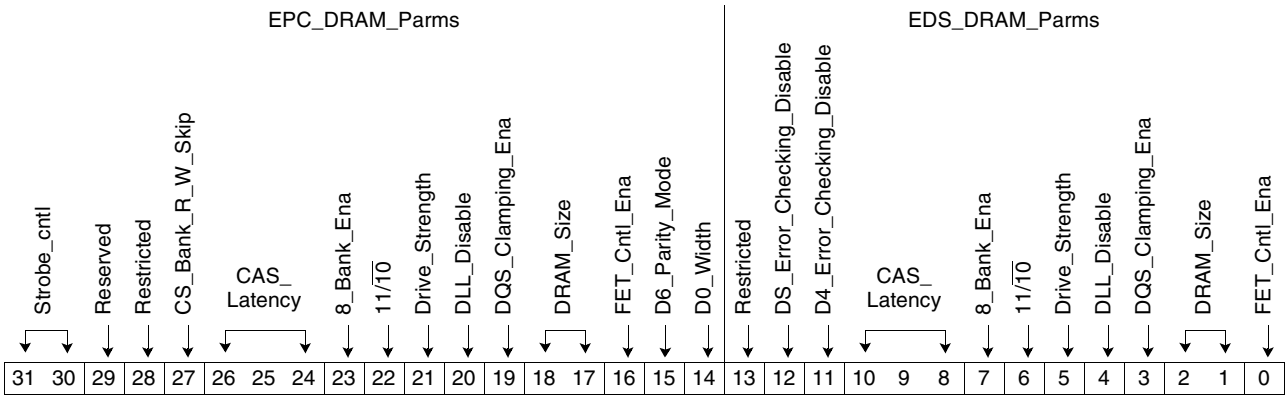
13.1.2 DRAM Parameter Register (DRAM_Parm)

The DRAM Parameter register controls the operation of the DRAMs used by the EPC and the Egress EDS. These DRAMs are controlled separately.

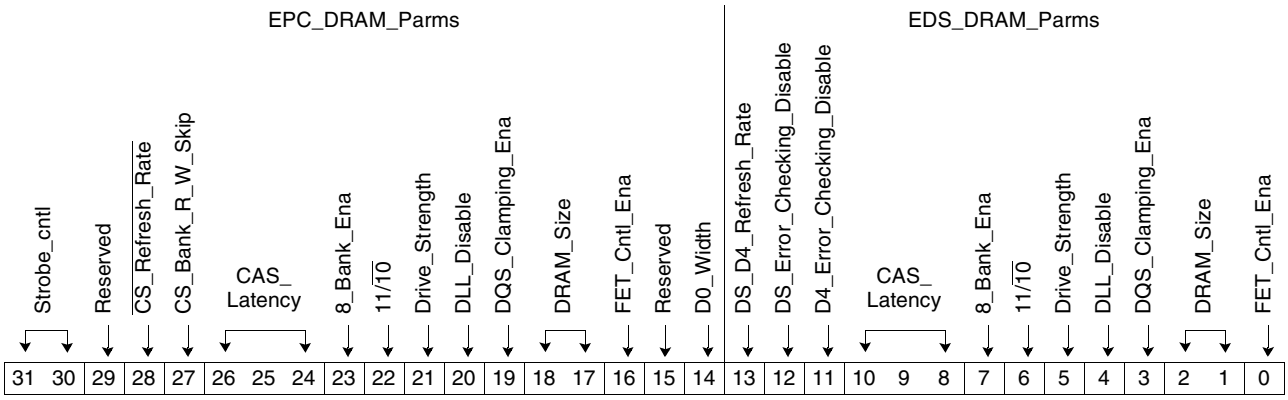
Access Type Read/Write

Base Address x'A000 2400'

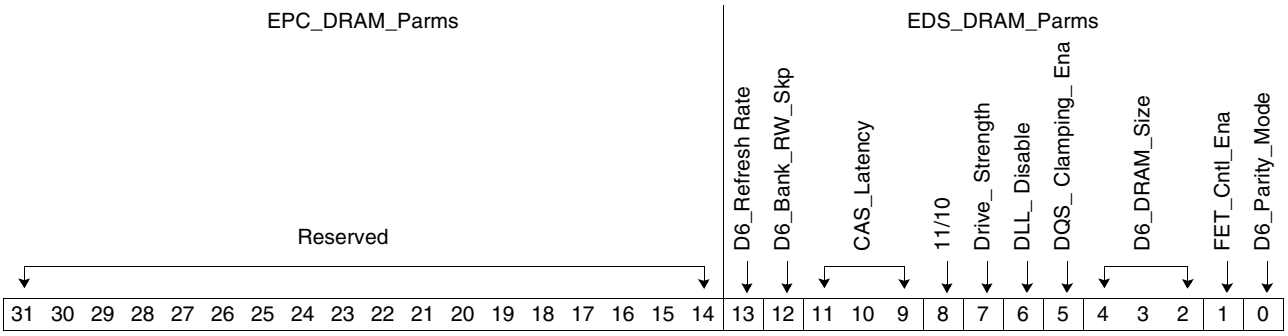
Base Address Offset 0



NP4GS3B (R2.0)
Base Address Offset 0



NP4GS3B (R2.0)
Base Address Offset 1



Base Address Offset 0

Field Name	Bit(s)	Reset	Description
Strobe_cntl	31:30	00	Strobe control for DDR DRAM interfaces. 00 Each DDR DRAM interface uses one strobe (xx_DQS) for each byte of data lines. 01 D0, D1, D2, D3 DDR DRAM interface use one strobe (xx_DQS) for each byte of data lines. DS0, DS1, and D4 DDR DRAM interface use one strobe (xx_DQS) for all data lines. 10 Reserved 11 Reserved Note: The above is available in NP4GS3B (R2.0) or later.
Reserved	29		Reserved
Restricted	28	1	Restricted Use only. Do not modify.
$\overline{\text{CS\_Refresh\_Rate}}$ (NP4GS3B (R2.0))	28	1	CS_Refresh_Rate. Controls the refresh rate for D0, D1, D2 and D3. 0 Double refresh rate (7.5 µs) 1 Normal refresh rate (15 µs)
CS_Bank_RW_Skp	27	0	This bit controls the number of banks that must be skipped within a DRAM access window when switching from a read to a write. 0 Skip 1 bank 1 Skip 2 banks The proper setting for this bit is related to the DRAM timing specifications and the CAS_Latency value. This control is for all control stores (D0, D1, D2, D3, D6).
CS_Bank_RW_Skp (NP4GS3B (R2.0))	27	0	This bit controls the number of banks that must be skipped within a DRAM access window when switching from a read to a write. 0 Skip 1 bank. CAS_Latency (bits 26:24) must be set to '010' to support this option. 1 Skip 2 banks The proper setting for this bit is related to the times of the DRAM with respect to the CAS_Latency value. This control is for D0, D1, D2 and D3 control stores.

Field Name	Bit(s)	Reset	Description
CAS_Latency	26:24, 10:8	010	DRAM Column Address Strobe Latency value corresponds to the DRAM's read latency measured from the Column Address. 000 - 001 Reserved 010 2 clock cycles (PC266A-compliant DRAMs) 011 3 clock cycles 100 - 101 Reserved 110 2.5 clock cycles (PC266B-compliant DRAMs) 111 Reserved
8_Bank_Enable	23, 7	0	Eight Bank Addressing Mode Enable control value. For proper operation, must be set to 0.
11/$\overline{10}$	22, 6	1	Eleven or ten cycle DRAM control value controls the number of core clock cycles the DRAM controller uses to define an access window. 0 10-cycle DRAM 1 11-cycle DRAM
Drive_Strength	21, 5	0	DRAM Drive Strength control 0 Strong 1 Weak
DLL_Disable	20, 4	0	DLL Disable control. For proper operation, must be set to 0.
DQS_Clamping_Ena	19, 3	0	DQS Clamping Enable control. For proper operation, must be set to 0.
DRAM_Size	18:17	00	DRAM Size indicates the size of the Control Stores D0-D3 in DRAMs. 00 4x1Mx16 DDR DRAM, Burst = 4 01 4x2Mx16 DDR DRAM, Burst = 4 10 4x4Mx16 DDR DRAM, Burst = 4 11 Reserved
FET_Cntl_Ena	16, 0	0	FET Control Enable control. For proper operation, must be set to 0.
Reserved	15		Reserved (NP4GS3B (R2.0)).
D6_Parity_Mode	15	1	DRAM D6 Parity Mode Disable control value (NP4GS3A (R1.1)). 0 D6 interface supports an additional two DDR DRAMs which support byte parity. The hardware generates on write and checks parity on read. 1 D6 interface does not support parity.
D0_Width	14	1	D0 Width control indicates if one or two DRAMs are used for the D0 CS. 0 Single wide configuration using one DRAM. A single bank access provides 64 bits of data. 1 Double wide configuration using two DRAMs. A single bank access provides 128 bits of data.
Restricted	13	0	Restricted use only (NP4GS3A (R1.1)). Do not modify.
DS_D4_Refresh_Rate	13	0	Refresh rate control for DS0, DS1 and D4 (NP4GS3B (R2.0)). 0 Normal refresh rate (15 μs) 1 Double refresh rate (7.5μs)
DS_Error_Checking_Disable	12	0	Egress Datastore Error Checking Disable control. When this field is set to 1, all DRAM error checking for the egress datastore is disabled.
D4_Error_Checking_Disable	11	0	D4 DRAM Error Checking Disable. When this field is set to 1, all DRAM error checking for the D4 DRAM is disabled.

Field Name	Bit(s)	Reset	Description
DRAM_Size	2:1	00	DRAM Size indicates the size of the Egress Datastore and D4 DRAMs. 00 4x1Mx16 DDR DRAM, Burst = 4, x2 01 4x2Mx16 DDR DRAM, Burst = 4, x2 10 4x4Mx16 DDR DRAM, Burst = 4, x2 11 Reserved The setting of this field affects the size of the extended stack queues as follows: GQ 00 01 10 11 GTQ 48 K 96 K 192 K Reserved GPQ 48 K 96 K 192 K Reserved GFQ 96 K 192 K 384 K Reserved GR0 96 K 192 K 384 K Reserved GR1 96 K 192 K 384 K Reserved GB0 96 K 192 K 384 K Reserved GB1 96 K 192 K 384 K Reserved Discard 96 K 192 K 384 K Reserved

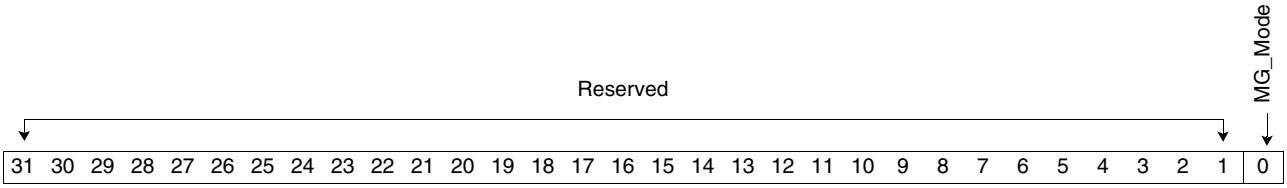
End NP4GS3B (R2.0)

13.2 Master Grant Mode Register (MG_Mode)

This configuration register configures the Master Grant I/O (MGrant_A, MGrant_B) for either nested priority or independent priority mode.

Access Type Read/Write

Base Address x'A000 0820'



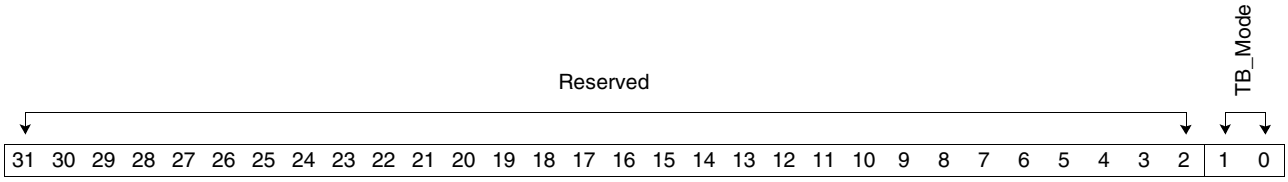
Field Name	Bit(s)	Reset	Description
Reserved	31:1		Reserved
MG_Mode	0	0	0 The MGrant I/O is defined for nested priority encoding which is defined as: 00 No grant (on any priority) 01 Priority 0 has grant 10 Priorities 0 and 1 have grant 11 Priorities 0, 1, and 2 have grant 1 The MGrant I/O is defined for independent priority encoding which is defined as: 00 No grant (on any priority) 01 Priority 0 and 1 have grant 10 Priority 2 has grant 11 Priority 0, 1, and 2 have grant

13.3 TB Mode Register (TB_Mode)

The target blade mode configures the maximum number of target network processors supported.

Access Type Read/Write

Base Address x'A000 0410'



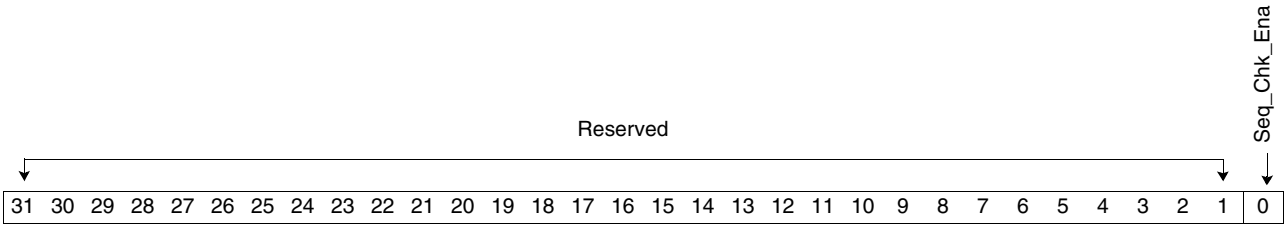
Field Name	Bit(s)	Reset	Description
Reserved	31:2		Reserved
TB_Mode	1:0	00	Target Blade Mode. This field is used to define the target blade mode currently in use by the NPR. The field is defined as: 00 16 blade mode. Valid addresses are 0:15. Multicast is indicated as a 16-bit vector. 01 Reserved 10 64 blade mode. Valid unicast target blade field encodes are 0 through 63. Multicast encodes are in the range of 512 through 65535. 11 Reserved

13.4 Egress Reassembly Sequence Check Register (E_Reassembly_Seq_Ck)

This configuration register enables sequence checking by the egress reassembly logic. The sequence checking insures that start of frame, optional middle of frame, and end of frame indications occur in the expected order for each cell of a frame being reassembled. Each cell that does not indicate start or end of frame carries a sequence number that is checked for proper order.

Access Type Read/Write

Base Address x'A000 0420'



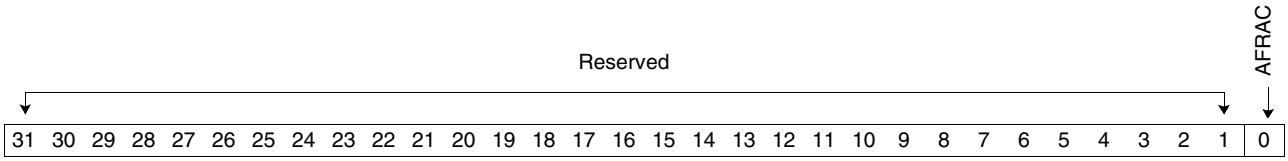
Field Name	Bit(s)	Reset	Description
Reserved	31:1		Reserved
Seq_Chk_Ena	0	1	Sequence Check Enable control 0 Sequence checking disabled 1 Sequence checking enabled for the E_EDS

13.5 Aborted Frame Reassembly Action Control Register (AFRAC)

This configuration register controls the action the hardware takes on a frame whose reassembly was aborted due to the receipt of an abort command in a cell header for the frame.

Access Type Read/Write

Base Address x'A000 0440'



Field Name	Bit(s)	Reset	Description
Reserved	31:1		Reserved
AFRAC	0	0	Aborted Frame Reassembly Action Control 0 Aborted frames are enqueued to the Discard Queue. 1 Aborted frames are enqueued with other frames on the associated GQ.

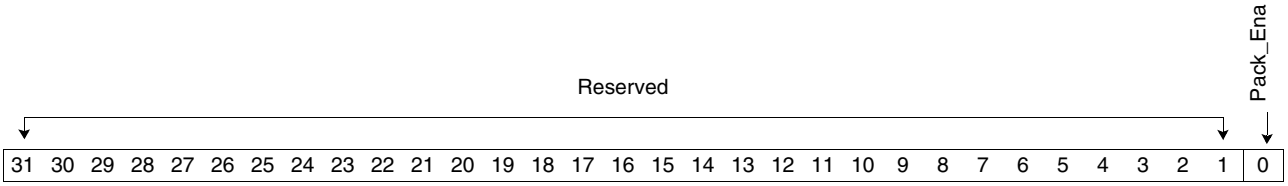
13.6 Packing Registers

13.6.1 Packing Control Register (Pack_Ctrl)

This configuration register is used to enable the transmission of packed cells across the switch interface. When enabled, the I-SDM determines if there is available space in the current cell being prepared for transmission and if there is an available packing candidate. A frame can be packed only if it is unicast, has the same target blade destination as the current frame, and is longer than 48 bytes. The packed frame starts on the next QW boundary following the last byte of the current frame. This control does not affect the ability of the E_EDS to receive packed cells.

Access Type Read/Write

Base Address x'A000 0480'



Field Name	Bit(s)	Reset	Description
Reserved	31:1		Reserved
Pack_Ena	0	1	Packing Enabled flag 0 Cell packing disabled 1 Cell packing enabled

13.6.2 Packing Delay Register (Pack_Dly) (NP4GS3B (R2.0))

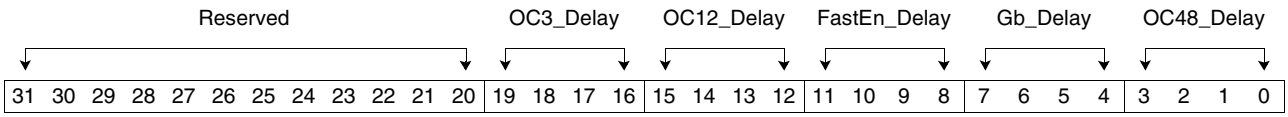
The Packing delay register is used to modify the ingress scheduler actions by the use of programmable wait periods per TB based on SP media speed, as determined by the DM_Bus_mode setting (see *13.22 Data Mover Unit (DMU) Configuration* on page 492). During processing of a frame for transmission across the switch interface, when it is determined that the next service will be the last for the frame and if there is no packing candidate at that time, then the selected TB run queue is not included in subsequent service selections. A timer is used per TB run queue to keep the queue out of the service selection until either the timer expires or a packing candidate (the corresponding SOF ring goes from empty to non-empty) is available.

Frames from the wrap DMU are not affected by this mechanism. Multicast frames (which include guided traffic) and the discard queues are not affected by this mechanism.

This function is disabled by setting the packing delay to 0.

Access Type Read/Write

Base Address x'A020 8000'



Field Name	Bit(s)	Reset	Description
Reserved	31:20		Reserved
OC3_Delay	19:16	0	Maximum packing delay in units of 3840 ns
OC12_Delay	15:12	0	Maximum packing delay in units of 960 ns
FastEn_Delay	11:8	0	Maximum packing delay in units of 4800 ns
Gb_Delay	7:4	0	Maximum packing delay in units of 480 ns
OC48_Delay	3:0	0	Maximum packing delay in units of 240 ns

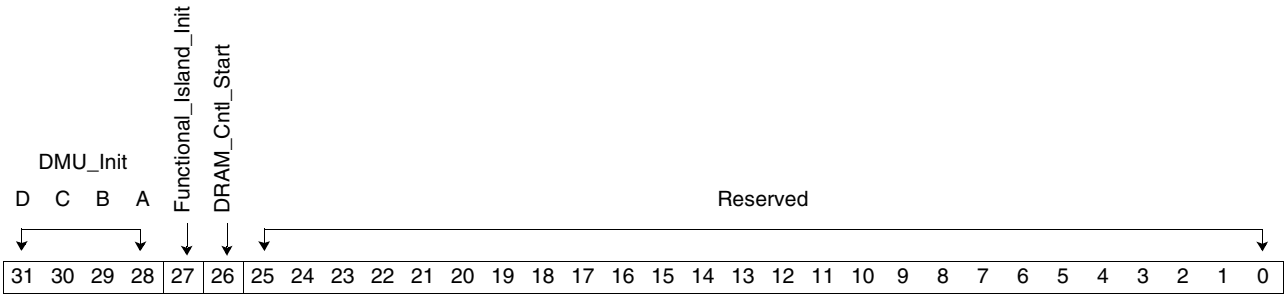
13.7 Initialization Control Registers

13.7.1 Initialization Register (Init)

This register controls the initialization of the functional islands. Each functional island and the DRAM Controllers begin initialization when the bits in this register are set to '1'. Each functional island signals the successful completion of initialization by setting its bit in the Init_Done Register. Once a functional island has been initialized, changing the state of these bits will no longer have any effect until a reset occurs.

Access Type Read/Write

Base Address x'A000 8100'



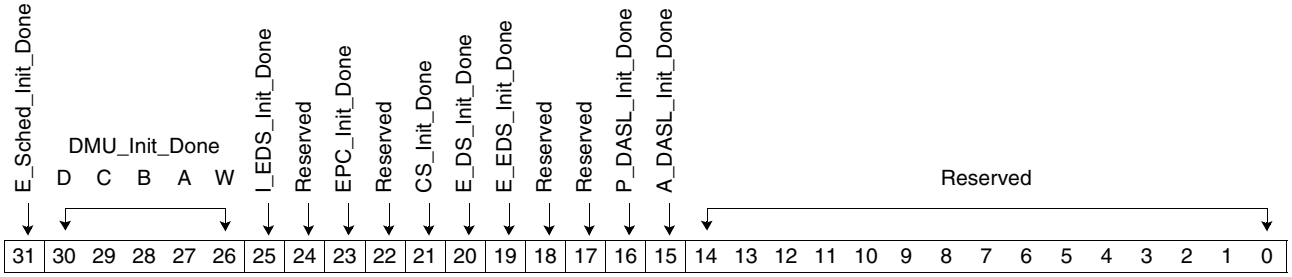
Field Name	Bit(s)	Reset	Description
DMU_Init	31:28	0000	Data Mover Unit Initialization control individually initializes each DMU.
Functional_Island_Init	27	0	Functional Island Initialization control. 0 Nop 1 Functional islands start hardware initialization. Completion of hardware initialization is reported in the Initialization Done Register.
DRAM_Cntl_Start	26	0	DRAM Controller Start Control. 0 Nop 1 Causes the DRAM Controllers to initialize and start operation. When initialization completes, the DRAM controllers set the CS_Init_Done and E-DS Init Done bits of the Initialization Done Register.
Reserved	25:0		Reserved

13.7.2 Initialization Done Register (Init_Done)

This register indicates that functional islands have completed their initialization when the corresponding bits are set to '1'. This register tracks the initialization state of the functional islands. The GCH reads this register during the initialization of the NP4GS3.

Access Type Read Only

Base Address x'A000 8200'

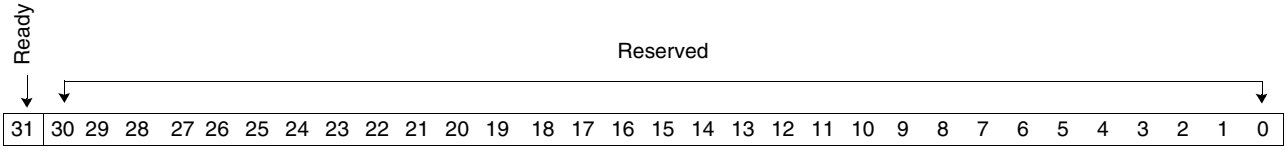


Field Name	Bit(s)	Reset	Description
E_Sched_Init_Done	31	0	Set to '1' by the hardware when the egress scheduler hardware completes its initialization.
DMU_Init_Done	30:26	0	Set to '1' by the hardware when the DMU hardware has completed its initialization. Bit DMU 30 D 29 C 28 B 27 A 26 Wrap
I_EDS_Init_Done	25	0	Set to '1' by the hardware when the Ingress EDS completes its initialization.
Reserved	24		Reserved
EPC_Init_Done	23	0	Set to '1' by the hardware when the EPC completes its initialization.
Reserved	22		Reserved
CS_Init_Done	21	0	Set to '1' by the hardware when the Control Store's DRAM controller completes its initialization.
E_DS_Init_Done	20	0	Set to '1' by the hardware when the Egress Data Stores' DRAM controller completes its initialization.
E_EDS_Init_Done	19	0	Set to '1' by the hardware when the Egress EDS completes its initialization
Reserved	18:17		Reserved
P_DASL_Init_Done	16	0	Set to '1' by the hardware when the primary DASL completes its initialization. The DASL interface continues to send synchronization cells.
A_DASL_Init_Done	15	0	Set to '1' by the hardware when the alternate DASL completes its initialization. The DASL interface continues to send synchronization cells.
Reserved	14:0		Reserved

13.8 NP4GS3 Ready Register (NPR_Ready)

Access Type Read/Write

Base Address x‘A004 0020’



Field Name	Bit(s)	Reset	Description
Ready	31	0	Ready is configured by picocode to drive a chip pin to indicate that the NP4GS3 has been initialized and is ready to receive Guided Traffic. 0 NP4GS3 not ready 1 NP4GS3 ready
Reserved	30:0		Reserved

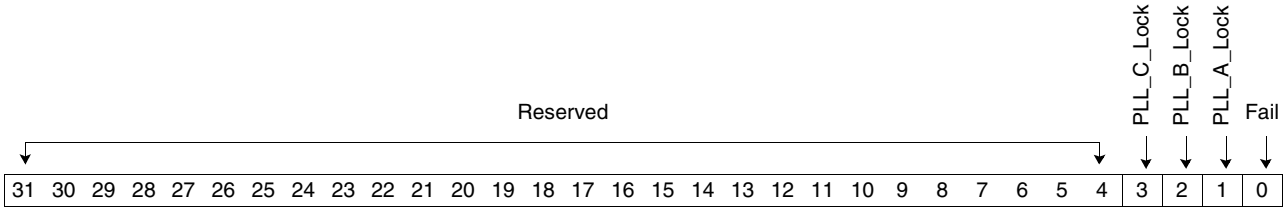
13.9 Phase Locked Loop Registers

13.9.1 Phase Locked Loop Fail Register (PLL_Lock_Fail)

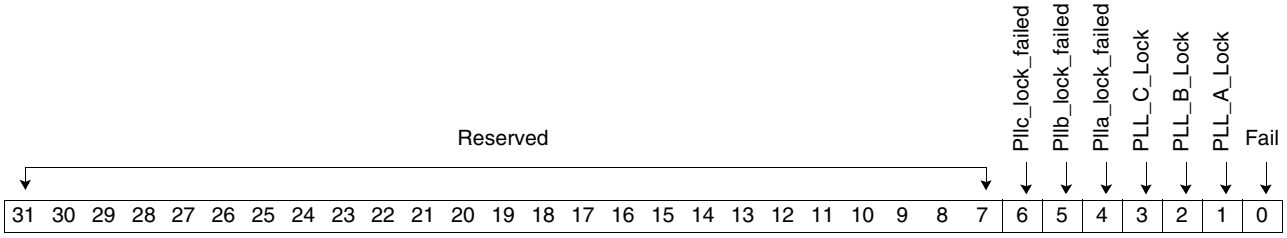
Access Type Read Only

Base Address x‘A000 0220’

NP4GS3A (R1.1)



NP4GS3B (R2.0)



Field Name	Bit(s)	Reset	Description
Reserved	31:7		Reserved. For NP4GS3A (R1.1), the reserved range is 31 to 3.
Pllc_lock_failed	6		Pllc_lock_failed. NP4GS3B (R2.0). 0 Pllc has stayed correctly locked continuously since the last reset. 1 Pllc has lost lock. (Lock was lost any time since the last reset)
Pllb_lock_failed	5		Pllb_lock_failed. NP4GS3B (R2.0). 0 Pllb has stayed correctly locked continuously since the last reset. 1 Pllb has lost lock. (Lock was lost any time since the last reset)
Plla_lock_failed	4		Plla_lock_failed. NP4GS3B (R2.0). 0 Plla has stayed correctly locked continuously since the last reset. 1 Plla has lost lock. (Lock was lost any time since the last reset)
PLL_C_Lock	3		Current status of lock indicator of the Core Clock PLL 0 Phase/frequency lock 1 Phase/frequency seek
PLL_B_Lock	2		Current status of lock indicator of the DASL-B PLL 0 Phase/frequency lock 1 Phase/frequency seek
PLL_A_Lock	1		Current status of lock indicator of the DASL-A PLL 0 Phase/frequency lock 1 Phase/frequency seek

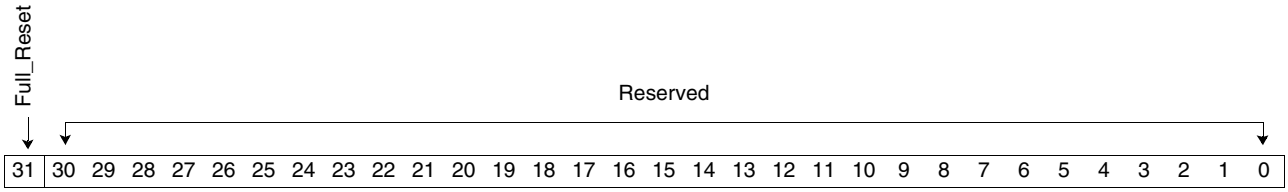
Field Name	Bit(s)	Reset	Description
Fail	0		Phased Locked Loop Fail indicator - indicates that an on-chip PLL has failed. This field is written by the clock logic. 0 PLLs OK 1 PLL failed If Fail is indicated at the end of the reset interval (101 μs after reset is started) the operational device I/O is set to '1'. After the end of the reset interval, a change in Fail will not affect operational device I/O. **Note:** For NP4GS3B (R2.0), the operational device I/O is not affected by the above.

13.10 Software Controlled Reset Register (Soft_Reset)

This register provides a control for software to reset the network processor.

Access Type Write Only

Base Address x‘A000 0240’



Field Name	Bit(s)	Reset	Description
Full_Reset	31	0	Full Reset value resets the NP4GS3 hardware via the picocode. This is the same full reset function provided by the Blade_Reset I/O. 0 Reserved 1 NP4GS3 performs an internal hardware reset.
Reserved	30:0		Reserved

13.11 Ingress Free Queue Threshold Configuration

13.11.1 BCB_FQ Threshold Registers

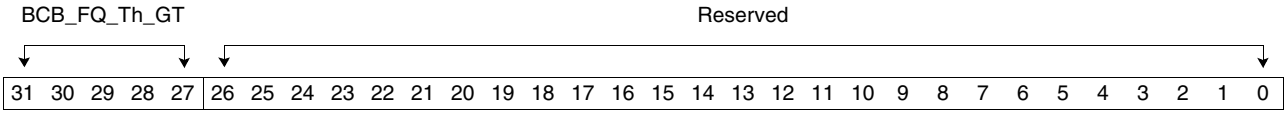
The value of the queue count in the BCB_FQ Control Block is continuously compared to the values each of the three threshold registers contains. The result of this comparison affects the NP4GS3's flow control mechanisms. The values in these registers must be chosen such that BCB_FQ_Th_GT ≤ BCB_FQ_Th_0 ≤ BCB_FQ_Th_1 ≤ BCB_FQ_Th_2. For proper operation the minimum value for BCB_FQ_Th_GT is x'08'.

13.11.2 BCB_FQ Threshold for Guided Traffic (BCB_FQ_Th_GT)

The Ingress EDS reads this register to determine when to discard all packets received.

Access Type Read/Write

Base Address x'A000 1080'



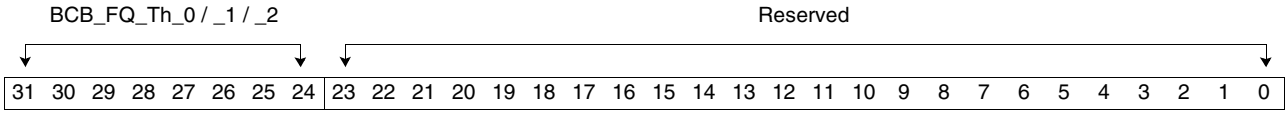
Field Name	Bit(s)	Reset	Description
BCB_FQ_Th_GT	31:27	x'08'	BCB Free Queue Threshold GT value is measured in units of individual buffers. For example, a threshold value of x'01' represents a threshold of one buffer.
Reserved	26:0		Reserved

13.11.3 BCB_FQ_Threshold_0 / _1 / _2 Registers (BCB_FQ_Th_0/_1/_2)

Access Type Read/Write

Base Address

BCB_FQ_Th_0	x‘A000 1010’
BCB_FQ_Th_1	x‘A000 1020’
BCB_FQ_Th_2	x‘A000 1040’



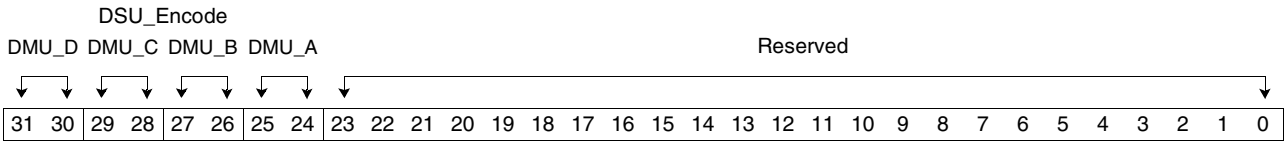
Field Name	Bit(s)	Reset	Description
BCB_FQ_Th_0 BCB_FQ_Th_1 BCB_FQ_Th_2	31:24	x‘00’	BCB Free Queue Threshold 0 / 1 / 2 value, as measured in units of 16 buffers. For example, a threshold value of x‘01’ represents a threshold of 16 buffers. The Ingress EDS reads this field to determine when to perform a discard action. Violation of this threshold (BCB queue count is less than this threshold) sends an interrupt to the EPC. When BCB_FQ_Th_0 is violated, the discard action is to perform partial packet discards. New data buffers are not allocated for frame traffic and portions of frames may be lost. When BCB_FQ_Th_1 is violated, the discard action is to perform packet discards. New data buffers are not allocated for new frame traffic, but frames already started continue to allocate buffers as needed.
Reserved	23:0		Reserved

13.12 Ingress Target DMU Data Storage Map Register (I_TDMU_DSU)

This register defines the Egress Data Storage Units (DSU) used for each DMU.

Access Type Read/Write

Base Address x'A000 0180'



Field Name	Bit(s)	Reset	Description
DSU_Encode	31:24	00	During enqueue operations, the values in this configuration register are loaded into the ingress Frame Control Block's DSU field when a DSU value is not specified by the enqueue. The hardware determines the target DMU from enqueue information and uses the corresponding field in this configuration register to load the DSU field. Four fields are defined, one for each DMU, with the following encode: 00 DSU 0 01 DSU 1 10 Reserved 11 DSU0, DSU1 Bits DMU 31:30 DMU_D 29:28 DMU_C 27:26 DMU_B 24:25 DMU_A
Reserved	23:0		Reserved

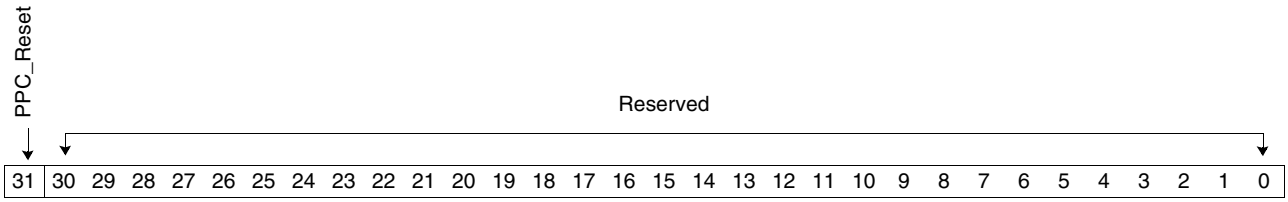
13.13 Embedded Processor Complex Configuration

13.13.1 PowerPC Core Reset Register (PowerPC_Reset)

This register contains a control value used to hold the PowerPC core in reset state.

Access Type Read/Write

Base Address x‘A000 8010’



Field Name	Bit(s)	Reset	Description
PPC_Reset	31	1	PowerPC Core Reset - Holds the PowerPC core in a reset state when set to 1. The rest of the PowerPC functional island is not affected by this control and can only be reset by a full reset. 0 PowerPC core reset disabled 1 PowerPC core held in reset
Reserved	30:0		Reserved

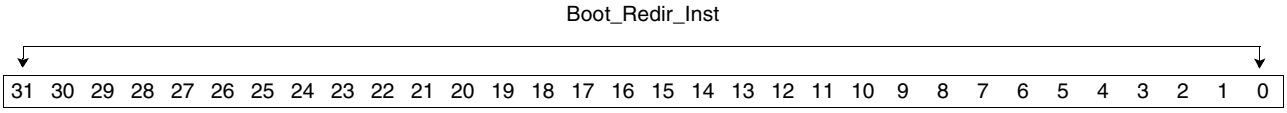
13.13.2 PowerPC Boot Redirection Instruction Registers (Boot_Redir_Inst)

In system implementations in which the embedded PowerPC boots from the D6 DRAM, the Mailbox and DRAM Interface macro performs PowerPC boot address redirection. Under these conditions, the hardware provides instructions that redirect the boot sequence to a location in the PowerPC's DRAM. Storage for eight instructions is provided by the Boot_Redir_Inst registers.

The PowerPC Boot Redirection Instruction (Boot_Redir_Inst) registers are accessed from the CAB Interface. These registers provide capacity for eight instructions for PLB addresses x'FFFF FFE0' - x'FFFF FFFC' These instructions redirect the PowerPC to boot from a location in the PowerPC's DRAM and are configured before the PPC_Reset is cleared.

Access Type Read/Write

Base Address x'3800 0110' - x'3800 0117'



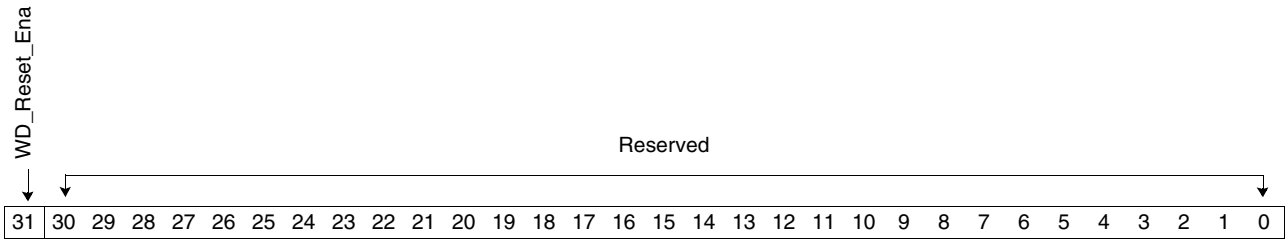
Field Name	Bit(s)	Reset	Description
Boot_Redir_Inst	31:0	x'0000 0000'	PowerPC boot redirection instruction address values contains instructions used by the PowerPC to redirect the boot sequence to a location in D6 DRAM. Offset — Corresponding PowerPC Instruction Address 0 — x'FFFF FFE0' 1 — x'FFFF FFE4' 2 — x'FFFF FFE8' 3 — x'FFFF FFEC' 4 — x'FFFF FFF0' 5 — x'FFFF FFF4' 6 — x'FFFF FFF8' 7 — x'FFFF FFFC'

13.13.3 Watch Dog Reset Enable Register (WD_Reset_Ena)

This register controls the action of a Watch Dog timer expiration. When set to 1, the second expiration of the Watch Dog timer causes a reset to the PowerPC core.

Access Type Read/Write

Base Address x‘A000 4800’



Field Name	Bit(s)	Reset	Description
WD_Reset_Ena	31	0	Reset Enable. 0 Disable reset of PowerPC core 1 Enable reset of PowerPC core on Watch Dog expire
Reserved	30:0		Reserved

13.13.4 Boot Override Register (Boot_Override)

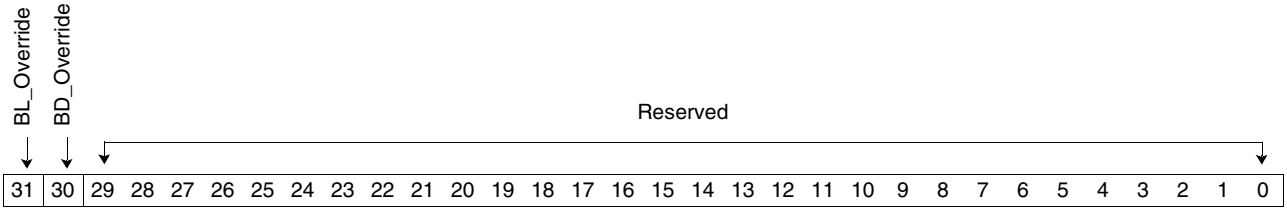
With the proper setting of the Boot_Picocode I/O (see *Table 2-30: Miscellaneous Pins* in the NP4GS3 Datasheet), this register provides boot sequence control.

When the Boot_Picocode I/O is held to 0, boot control is given over to the SPM interface hardware. When the SPM completes its boot actions, a POR interrupt is set (Interrupt vector 1, bit 0) which causes the GFH to start execution.

When the Boot_Picocode I/O is held to 1, boot control is given over to an external source, either a host on the PCI or the ePPC. When boot is completed, a CAB write is required to set BD_Override to 1 which causes a POR interrupt (Interrupt vector 1, bit 0), causing the GFH to start execution.

Access Type Read/Write

Base Address x‘A000 8800’

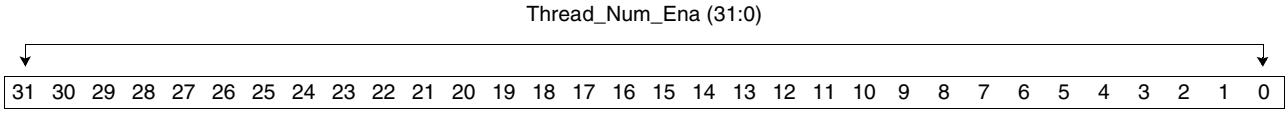


Field Name	Bit(s)	Reset	Description
BL_Override	31	See description	This is set to the value of the boot_picocode I/O during reset. 0 Boot code is loaded by the SPM interface state machine. 1 Boot code is loaded by intervention of software. The boot code can be loaded using the CABWatch interface, using the PCI bus, or by using the embedded Power PC. When reset to ‘1’, a CAB write can set this field to ‘0’ to start the SPM interface controlled boot sequence. The SPM interface reads this field to control the behavior of its state machine.
BD_Override	30	0	Boot Done Override control value. 0 Nop 1 When the SPM interface controlled boot loading sequence is overridden, this bit is set after the EPC’s Instruction Memory has been loaded to start the EPC. A CAB write can set this field to ‘1’ to indicate that the EPC’s Instruction Memory is loaded. The Configuration Register logic reads this field when generating the POR Interrupt to the EPC.
Reserved	29:0		Reserved

13.13.5 Thread Enable Register (Thread_Enable)

This register contains control information used to enable or disable each thread.

Access Type	Read/Write	Bits 31:1
	Read Only	Bit 0
Base Address	x‘A000 8020’	



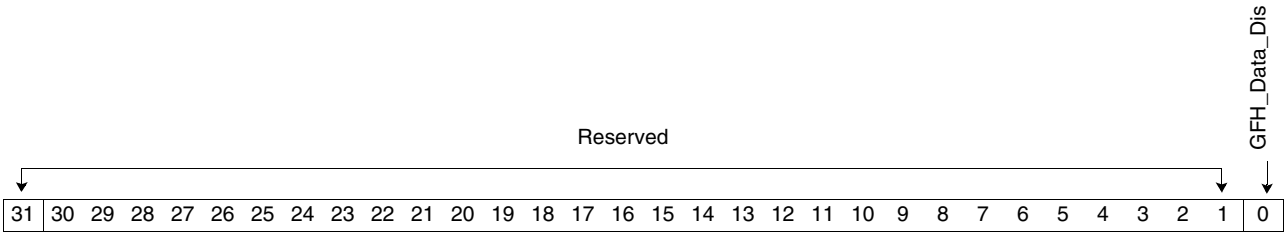
Field Name	Bit(s)	Reset	Description
Thread_Num_Ena (31:1)	31:1	0	Thread enable. 0 Disabled 1 Corresponding thread enabled for use
Thread_Num_Ena 0	0	1	Thread 0 (the GFH) is always enabled and cannot be disabled through this bit.

13.13.6 GFH Data Disable Register (GFH_Data_Dis)

This register is used to enable the Dispatch to assign data frames to the GFH for processing.

Access Type Read/Write

Base Address x‘24C0 0030’



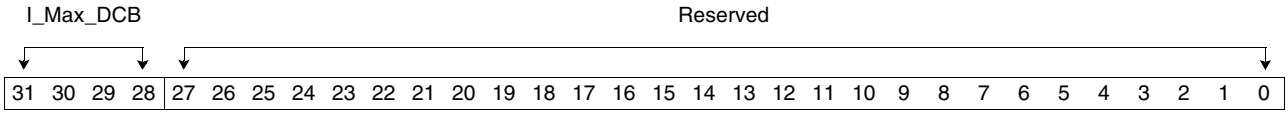
Field Name	Bit(s)	Reset	Description
Reserved	31:1		Reserved
GFH_Data_Dis	0	0	Guided Frame Handler Data Enable control. 0 Enabled 1 Not Enabled This field is configured to enable or disable the dispatching of data frames to the GFH.

13.13.7 Ingress Maximum DCB Entries (I_Max_DCB)

This register defines the maximum number of ingress frames that are currently allowed to be simultaneously serviced by the Dispatch unit. This limits the total number of ingress frames occupying space in the dispatch control block.

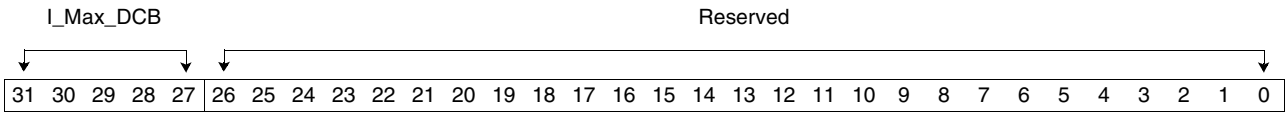
Access Type Read/Write

Base Address x‘2440 0C40’



Field Name	Bit(s)	Reset	Description
I_Max_DCB	31:28	x‘6’	Maximum number of ingress frames allowed service in the dispatch control block.
Reserved	27:0		Reserved

NP4GS3B (R2.0)



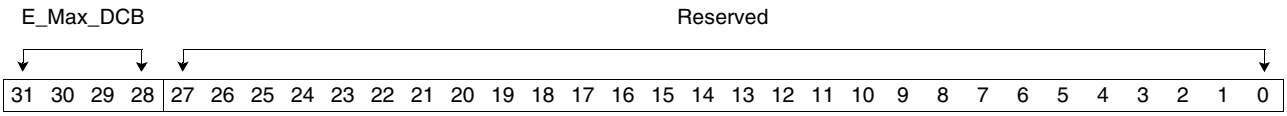
Field Name	Bit(s)	Reset	Description
I_Max_DCB	31:27	x‘80’	Maximum number of ingress frames allowed service in the dispatch control block.
Reserved	26:0		Reserved

13.13.8 Egress Maximum DCB Entries (E_Max_DCB)

This register defines the maximum number of egress frames that are currently allowed to be simultaneously serviced by the Dispatch unit. This limits the total number of egress frames occupying space in the dispatch control block.

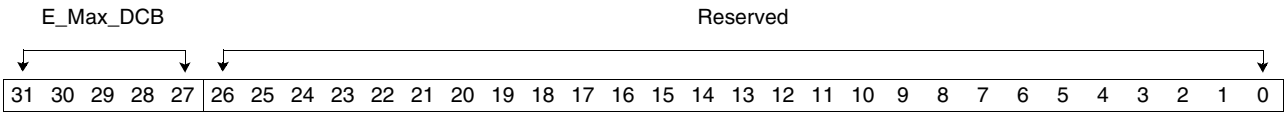
Access Type Read/Write

Base Address x‘2440 0C50’



Field Name	Bit(s)	Reset	Description
E_Max_DCB	31:28	x‘6’	Maximum number of egress frames allowed service in the dispatch control block.
Reserved	27:0		Reserved

NP4GS3B (R2.0)



Field Name	Bit(s)	Reset	Description
E_Max_DCB	31:27	x‘80’	Maximum number of ingress frames allowed service in the dispatch control block.

Field Name	Bit(s)	Reset	Description
Reserved	31:6		Reserved
TB	5:0	0	Blade address of this network processor. The value in this field is limited by the TB_Mode configured (See *Section 13.3* on page 446). It is further limited when configured for DASL Wrap mode (See *Section 13.29.1* on page 502) to a value of either 1 or 0.

13.13.10 Local Target Blade Vector Register (Local_TB_Vector)

This register is used to determine the interface used when forwarding traffic. The register is defined as a target blade bit vector where each bit in the register represents a target blade address.

For unicast traffic, in all target blade modes, the target blade address (defined in both the FCBPage and FCB2) is used to select the appropriate bit in the register for comparison. If the selected bit is set to 1, then local DASL interface is used to transmit the cell, otherwise the remote DASL interface is used.

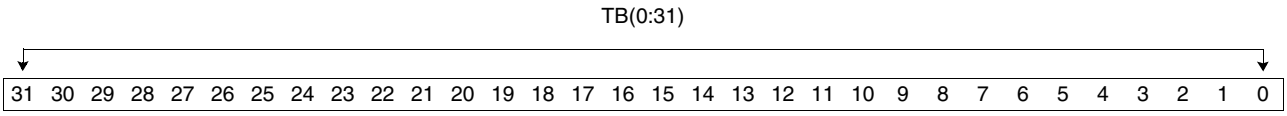
For multicast traffic (in 16 blade mode only) the target blade address, (defined in both the FCBPage and FCB2 as a bit vector) is compared bit by bit to the contents of this register. When a bit in the target blade address is set to 1, and the corresponding bit in this register is also set to 1, then the local DASL interface is used to transmit the cell. When a bit in the target blade address is set to 1 and the corresponding bit in this register is set to 0, then the remote DASL interface is used to transmit the cell.

For multicast traffic (in 64 blade mode) the Local MCTarget Blade Vector Register is used (see *Local MCTarget Blade Vector Register (Local_MC_TB_Max)* on page 470).

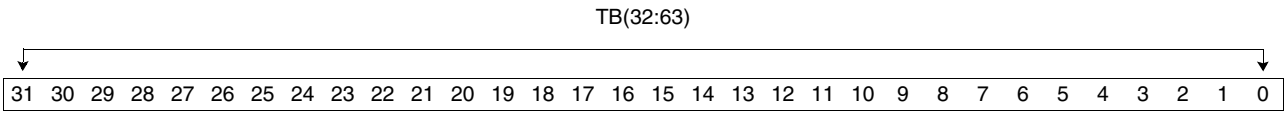
Access Type Read/Write

Base Addresses x‘A000 4100’

Base Address Offset 0



Base Address Offset 1



Base Address Offset 0

Field Name	Bit(s)	Reset	Description
TB(0:31)	31:0	0	This is a bit vector representing target blade addresses 0 to 31.

Base Address Offset 1

Field Name	Bit(s)	Reset	Description
TB(32:63)	31:0	0	This is a bit vector representing target blade addresses 32 to 63.

13.13.11 Local MCTarget Blade Vector Register (Local_MC_TB_Max)

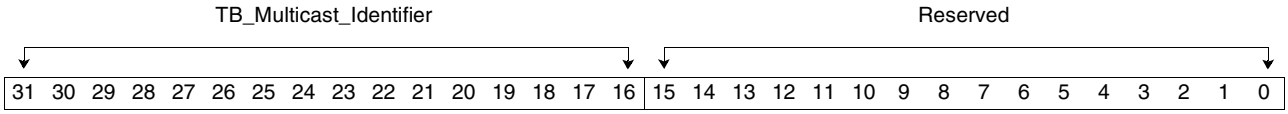
When configured for 64 blade mode, with both the DASL-A and the DASL-B active, this register is used to determine the interface to be used when forwarding multicast traffic.

The target blade address (defined in both the FCBPage and FCB2) is compared to the value in the TB_Multicast_Indentifier field. If the target blade address is less than this value, then the local DASL interface is used to transmit the cell, otherwise the remote DASL interface is used.

The TB_Multicast_Indentifier field is reset to 0, causing all multicast traffic to use the remote DASL, during power on.

Access Type Read/Write

Base Addresses x'A000 4200'



Field Name	Bit(s)	Reset	Description
TB_Multicast_Identifier	31:16	0	Multicast local maximum. The TB field for a frame is compared to the value of this field; when smaller the frame is local. Used only when not configured for 16 blade mode.
Reserved	15:0		Reserved

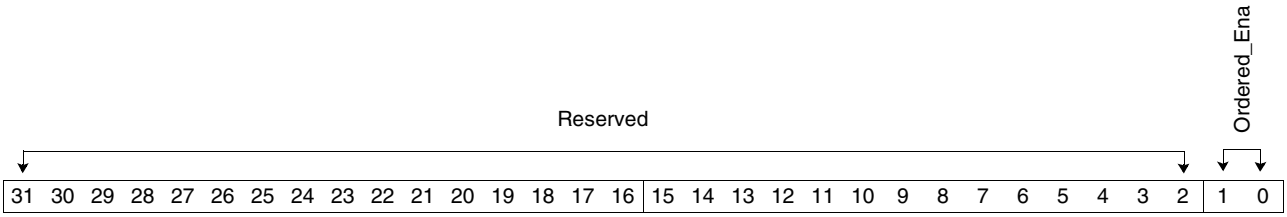
13.13.12 Ordered Semaphore Enable Register (Ordered_Sem_Ena) (NP4GS3B (R2.0))

This register enables ordered semaphore operation in the NP4GS3. When ordered semaphores are enabled, a thread is restricted to only locking one semaphore at a time. When ordered semaphores are disabled, a thread may hold locks on two unordered semaphores at a time.

Failure to follow these restrictions will result in unpredictable operation.

Access Type Read/Write

Base Addresses x'2500 0180'



Field Name	Bit(s)	Reset	Description
Reserved	31:2		Reserved
Ordered_Ena	1:0	0	00 Ordered semaphores disabled 01 Ordered semaphores enabled for Ordered Semaphore ID Queue 0 10 Ordered semaphores enabled for Ordered Semaphore ID Queue 1 11 Ordered semaphores enabled for both Ordered Semaphore ID Queues 0 and 1.

13.14 Flow Control Structures

13.14.1 Ingress Flow Control Hardware Structures

13.14.1.1 Ingress Transmit Probability Memory Register (I_Tx_Prob_Mem)

The Ingress Flow Control Hardware contains an internal memory that holds 64 different transmit probabilities for Flow Control.

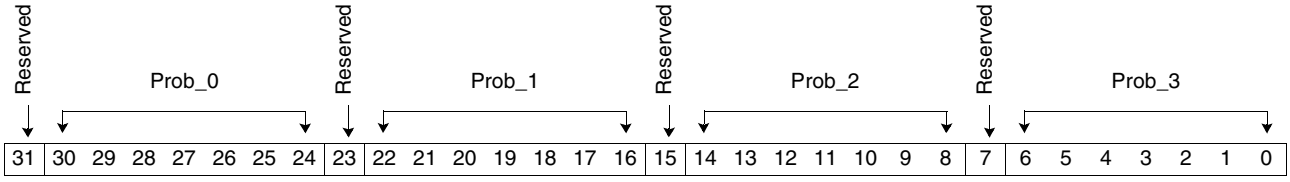
The probability memory occupies 16 entries in the CAB address space. Each probability entry in the CAB is 32 bits wide and contains four 7-bit probabilities. The 4-bit access address to each probability entry comprises two components: the 3-bit QosClass field (QQQ) and the 1-bit Remote Egress Status Bus value for the current priority (T). The address is formed as QQQT. The QosClass is taken from the Ingress FCBPage. The Remote Egress Status Bus value for the current priority reflects the threshold status of the Egress' leased twin count.

The Ingress Flow Control Hardware accesses probabilities within each probability memory entry by using the 2-bit Color portion of the FC_Info field taken from the Ingress FCBPage as an index. The probabilities are organized as shown below.

Access Type Read/Write

Base Address x'3000 00#0'

Note: 'The base address is listed with a '#' replacing one of the hex digits. The '#' ranges from x'0' to x'F', and indicates which probability entry is being referenced.



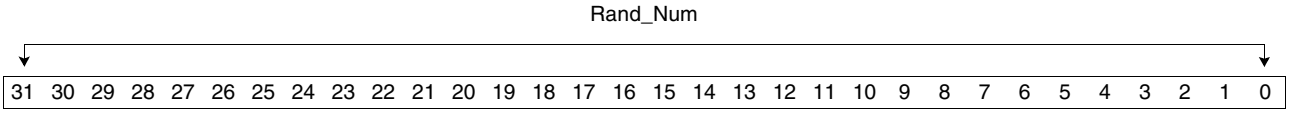
Field Name	Bit(s)	Reset	Description
Reserved	31		Reserved
Prob_0	30:24		Transmit Probability 0 - transmit probability accessed when Color is '11'
Reserved	23		Reserved
Prob_1	22:16		Transmit Probability 1 - transmit probability accessed when Color is '10'
Reserved	15		Reserved
Prob_2	14:8		Transmit Probability 2 - transmit probability accessed when Color is '01'
Reserved	7		Reserved
Prob_3	6:0		Transmit Probability 3 - transmit probability accessed when Color is '00'

13.14.1.2 Ingress Pseudo-Random Number Register (I_Rand_Num)

This register contains a 32-bit pseudo-random number used in the Flow Control algorithms. The CAB accesses this register in order to modify its starting point in the pseudo-random sequence. However, a write to this register is not necessary to start the pseudo-random sequence: it starts generating pseudo-random numbers as soon as the reset is finished.

Access Type Read/Write

Base Addresses x'3000 0100'



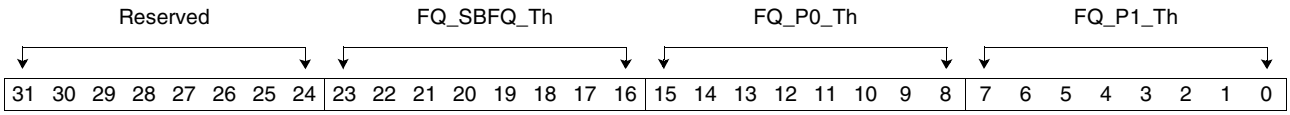
Field Name	Bit(s)	Reset	Description
Rand_Num	31:0		32-bit pseudo-random number

13.14.1.3 Free Queue Thresholds Register (FQ_Th)

This register contains three thresholds that are compared against the Ingress Free Queue. The results of this comparison are used in the Flow Control algorithms. Thresholds are in units of 16 buffers.

Access Type Read/Write

Base Addresses x‘A040 0020’



Field Name	Bit(s)	Reset	Description
Reserved	31:24		Reserved
FQ_SBFQ_Th	23:16	x‘FF’	Threshold for comparison to the Ingress Free queue count (BCB_FQ). When the number of buffers indicated by BCB_FQ is less than the number of buffers indicated by FQ_SBFQ_Th, then I_FreeQ_Th I/O is set to 1.
FQ_P0_Th	15:8	x‘FF’	Threshold for comparison to the Ingress Free queue count (BCB_FQ), when determining flow control actions against Priority 0 traffic. When the number of buffers indicated by BCB_FQ is less than the number of buffers indicated by FQ_P0_Th, then flow control hardware discards the frame.
FQ_P1_Th	7:0	x‘FF’	Threshold for comparison to the Ingress Free queue count (BCB_FQ), when determining flow control actions against Priority 0 traffic. When the number of buffes indicated by BCB_FQ is less than the number of buffers indicated by FQ_P1_Th, then flow control hardware discards the frame.

13.14.2 Egress Flow Control Structures

13.14.2.1 Egress Transmit Probability Memory (E_Tx_Prob_Mem) Register

The Egress Flow Control Hardware contains an internal memory that holds 64 different transmit probabilities for Flow Control.

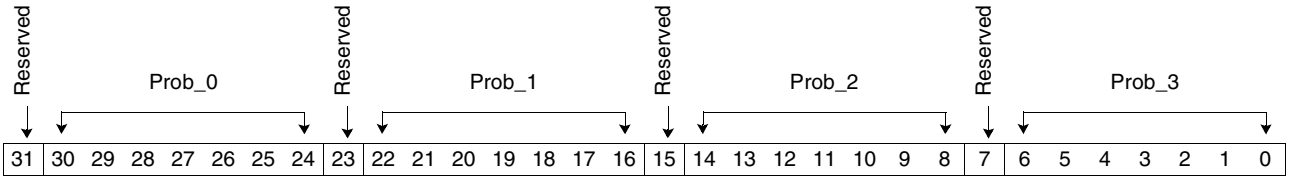
The probability memory occupies 16 entries in the CAB address space. Each probability entry in the CAB is 32 bits wide and contains four 7-bit probabilities. An entry in the Egress Probability Memory is accessed by using the 4-bit FC_Info field taken from the Egress FCBPage as an index.

The Egress Flow Control Hardware uses a 2-bit address to access the probabilities within each probability memory entry. This address (formed as FP) comprises two components: a 1-bit “threshold exceeded” value for the current priority of the flow queue count (see *Section 4.7.1* on page 355), and a 1-bit “threshold exceeded” value for the current priority of the combined flow/port queue count (see *Section 4.7.2* on page 363).

Access Type Read/Write

Base Addresses x‘B000 00#0’

Note: The base address is listed with a ‘#’ replacing one of the hex digits. The ‘#’ ranges from x‘0’ to x‘F’, and indicates which probability entry is being referenced.



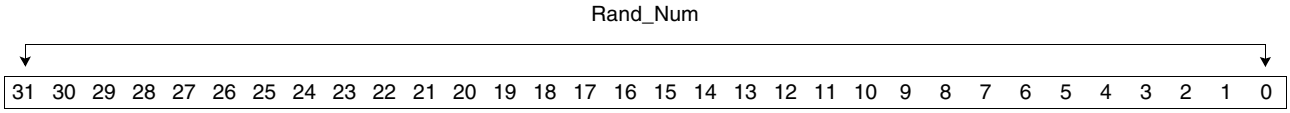
Field Name	Bit(s)	Reset	Description
Reserved	31		Reserved
Prob_0	30:24		Transmit Probability 0 - transmit probability accessed when ‘FP’ is ‘11’
Reserved	23		Reserved
Prob_1	22:16		Transmit Probability 1 - transmit probability accessed when ‘FP’ is ‘10’
Reserved	15		Reserved
Prob_2	14:8		Transmit Probability 2 - transmit probability accessed when ‘FP’ is ‘01’
Reserved	7		Reserved
Prob_3	6:0		Transmit Probability 3 - transmit probability accessed when ‘FP’ is ‘00’

13.14.2.2 Egress Pseudo-Random Number (E_Rand_Num)

This register contains a 32-bit pseudo-random number used in the Flow Control algorithms. The CAB accesses this register in order to modify its starting point in the pseudo-random sequence. However, a write to this register is not necessary to start the pseudo-random sequence: it starts generating pseudo-random numbers as soon as the reset is finished.

Access Type Read/Write

Base Addresses x‘B000 0100’



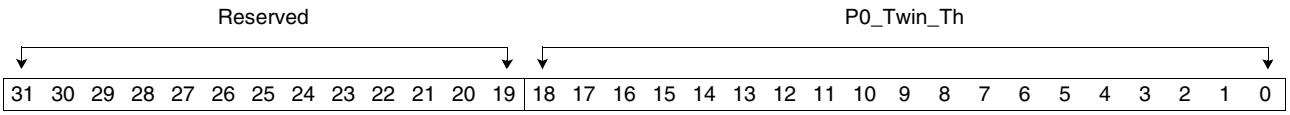
Field Name	Bit(s)	Reset	Description
Rand_Num	31:0		32-bit pseudo-random number

13.14.2.3 P0 Twin Count Threshold (P0_Twin_Th)

This register contains the threshold value that is compared against the Priority 0 Twin Count. The results of this comparison are used in the Flow Control algorithms.

Access Type Read/Write

Base Addresses x'A040 0100'



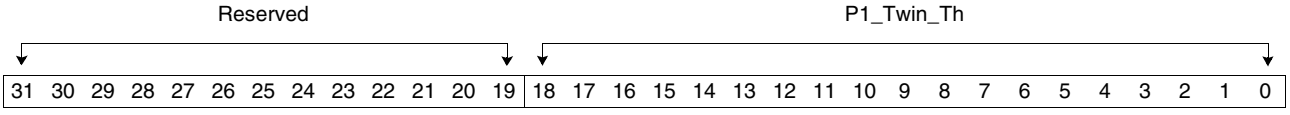
Field Name	Bit(s)	Reset	Description
Reserved	31:19		Reserved
P0_Twin_Th	18:0	x'0 0000'	P0 Twin Count Threshold value used in the Egress Flow Control Hardware algorithm.

13.14.2.4 P1 Twin Count Threshold (P1_Twin_Th)

This register contains the threshold value that is compared against the Priority 1 Twin Count. The results of this comparison are used in the Flow Control algorithms.

Access Type Read/Write

Base Addresses x'A040 0200'



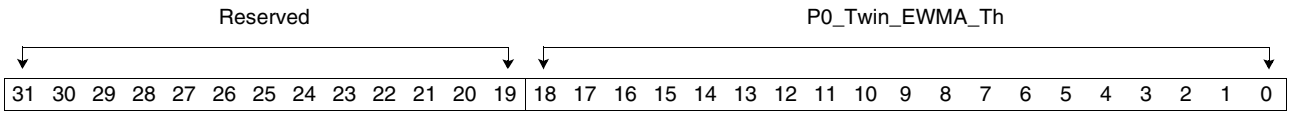
Field Name	Bit(s)	Reset	Description
Reserved	31:19		Reserved
P1_Twin_Th	18:0	x'0 0000'	P1 Twin Count Threshold value used in the Egress Flow Control Hardware algorithm.

13.14.2.5 Egress P0 Twin Count EWMA Threshold Register (E_P0_Twin_EWMA_Th)

This register contains the threshold value that is compared against the Egress P0 Twin Count EWMA (see *Section 4.11.2* on page 380). The results of this comparison are placed on the Remote Egress Status Bus.

Access Type Read/Write

Base Addresses x‘A040 0400’



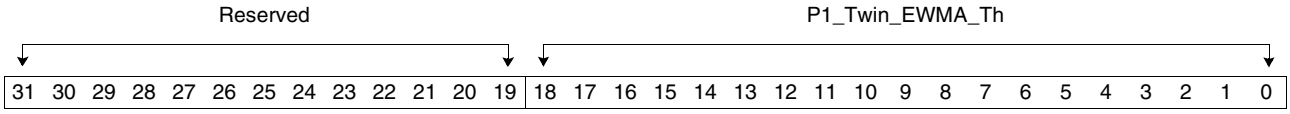
Field Name	Bit(s)	Reset	Description
Reserved	31:19		Reserved
P0_Twin_EWMA_Th	18:0	x‘0 0000’	Priority 0 Egress Leased Twin Count Exponentially Weighted Moving Average Threshold value. This value is compared against the Egress P0 Twin Count EWMA and its result placed on the Remote Egress Status Bus.

13.14.2.6 Egress P1 Twin Count EWMA Threshold Register (E_P1_Twin_EWMA_Th)

This register contains the threshold value that is compared against the Egress P1 Twin Count EWMA (see *Section 4.11.3* on page 381). The results of this comparison are placed on the Remote Egress Status Bus.

Access Type Read/Write

Base Addresses x‘A040 0800’



Field Name	Bit(s)	Reset	Description
Reserved	31:19		Reserved
P1_Twin_EWMA_Th	18:0	x‘0 0000’	Egress Priority 1 Twin Count Exponentially Weighted Moving Average Threshold value. This value is compared against the Egress P1 Twin Count EWMA and its result placed on the Remote Egress Status Bus.

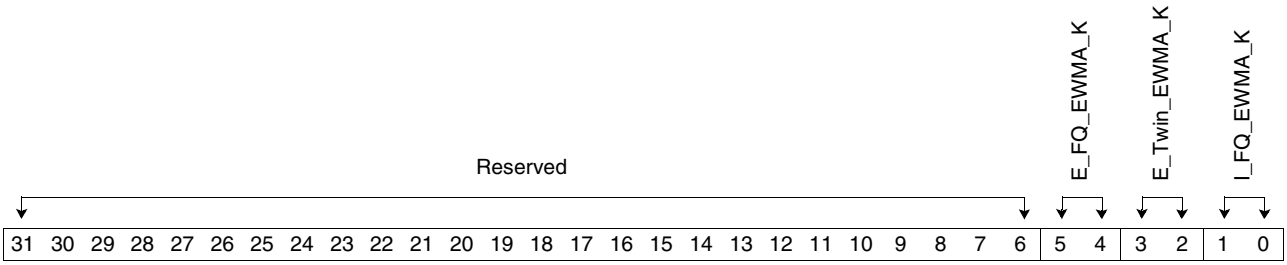
13.14.3 Exponentially Weighted Moving Average Constant (K) Register (EWMA_K)

This register contains Constant (K) values for the various Exponentially Weighted Moving Averages calculated in the Ingress and Egress Flow Control Hardware. The K value is encoded as follows:

K encoding	Constant Value
00	1
01	1/2
10	1/4
11	1/8

Access Type Read/Write

Base Addresses x'A040 0040'



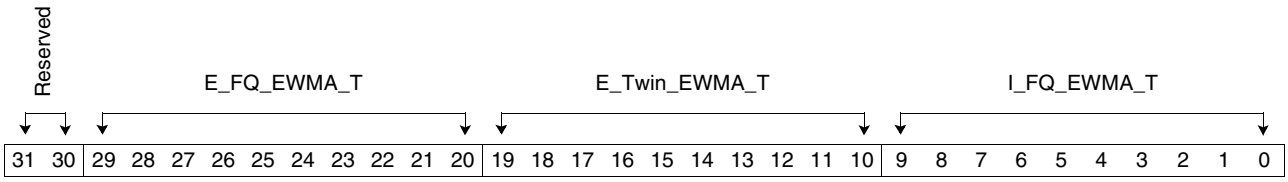
Field Name	Bit(s)	Reset	Description
Reserved	31:6		Reserved
E_FQ_EWMA_K	5:4	00	K value for the Egress Free Queue Count Exponentially Weighted Moving Average calculation in the Egress Flow Control Hardware.
E_Twin_EWMA_K	3:2	00	K value for the Egress P0/P1 Twin Count EWMA calculation in the Egress Flow Control Hardware.
I_FQ_EWMA_K	1:0	00	K value for the Ingress Free Queue Count Exponentially Weighted Moving Average calculation in the Ingress Flow Control Hardware.

13.14.4 Exponentially Weighted Moving Average Sample Period (T) Register (EWMA_T)

This register contains the sample periods for the various Exponentially Weighted Moving Averages calculated in the Ingress and Egress Flow Control Hardware. The values in this register are the number of 10 μs multiples for the interval between calculations of the respective ExpWAs. The computation of an EWMA does not occur unless the respective field in this register is non-zero.

Access Type Read/Write

Base Addresses x‘A040 0080’



Field Name	Bit(s)	Reset	Description
Reserved	31:30		Reserved
E_FQ_EWMA_T	29:20	x‘000’	Sample Period for the Egress Free Queue Count Exponentially Weighted Moving Average calculation in the Egress Flow Control Hardware.
E_Twin_EWMA_T	19:10	x‘000’	Sample Period for the Egress P0/P1 Twin Count EWMA calculation in the Egress Flow Control Hardware.
I_FQ_EWMA_T	9:0	x‘000’	Sample Period for the Ingress Free Queue Count Exponentially Weighted Moving Average calculation in the Ingress Flow Control Hardware.

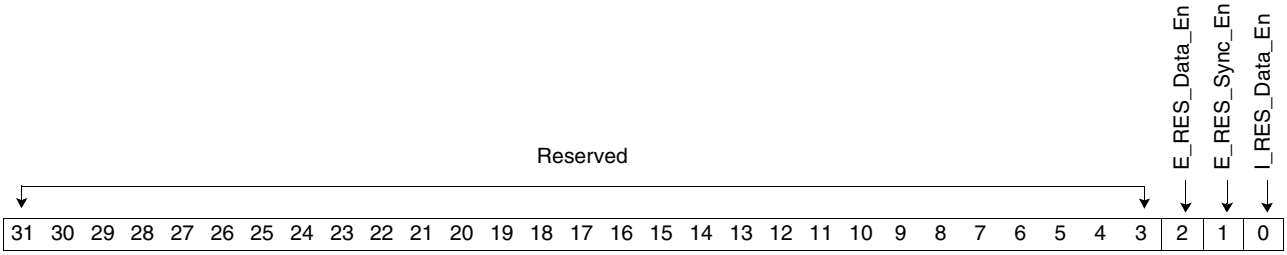
13.14.5 Remote Egress Status Bus Configuration Enables (RES_Data_Cnf)

This register controls operation of the Remote Egress Status Bus. The Remote Egress Status Bus is a 2-bit bus that allows communication between the system made up of all of the Egress Flow Control Hardware components and the system made up of all of the Ingress Flow Control Hardware. One bit of this bus is the sync pulse, and the other bit is TDM Data reflecting the status of the Egress Leased Twin Counts as they relate to their respective thresholds.

Access Type Read/Write

Base Addresses x'A000 0880'

Base Address Offset 0



Base Address Offset 0

Field Name	Bit(s)	Reset	Description
Reserved	31:3		Reserved
E_RES_Data_En	2	1	Egress Remote Egress Status Bus Data enable. 0 Sets the RES_Data I/O to a Hi-Z state. 1 Places data about this NP4GS3's egress data store congestion state.
E_RES_Sync_En	1	0	Egress Remote Egress Status Bus Sync enable. When this field is set to 1, the NP4GS3 transmits a sync pulse every Remote Egress Status Bus interval. Only one network processor in a system will have this bit enabled.
I_RES_Data_En	0	1	Ingress Remote Egress Status Bus Data enable. 0 Disables use of the Remote Egress Status Bus for ingress flow control. The Ingress Flow Control Hardware treats the Remote Egress Status Bus as if it contained all 0s. 1 Enables use of the Remote Egress Status Bus for ingress flow control. Values are captured for each remote target blade and used for ingress flow control.

13.15 Target Port Data Storage Map (TP_DS_MAP) Register

The Target Port Data Storage Map indicates in which data store, DS_0 or DS_1 or both, that data is found for a port. Each port is configured with two bits; when set to 1, it indicates the data is found in the corresponding data store.

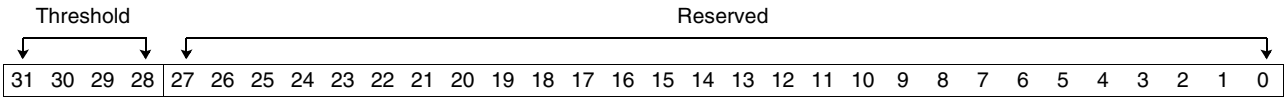
13.16 Egress SDM Stack Threshold Register (E_SDM_Stack_Th)

Access Type Read/Write

Base Address x‘A000 1800’



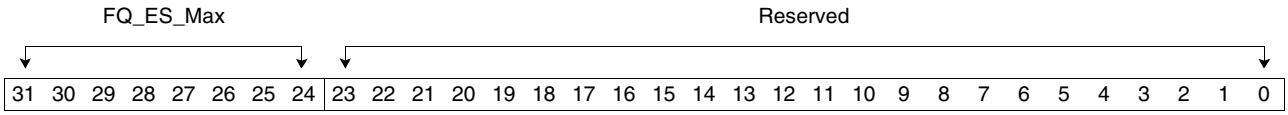
Field Name	Bit(s)	Reset	Description
Threshold	31:28	x‘8’	E-SDM Stack Threshold value. When this threshold is violated (threshold value is less than the count of empty entries in the E-SDM Stack), send grant is set to its disable state.
Reserved	27:0		Reserved

13.17 Free Queue Extended Stack Maximum Size (FQ_ES_Max) Register

This register sets the number of buffers that are released into the free queue and thus made available for the storage of received frames. The egress EDS reads this register when building the FQ_ES.

Access Type Read/Write

Base Address x‘A000 2100’



Field Name	Bit(s)	Reset	Description
FQ_ES_Max	31:24	x‘08’	Maximum size of the Free Queue Extended Stack measured in increments of 2 K buffer twins. The Egress EDS reads this value when building the FQ_ES. The maximum size is limited by the DDR DRAM used by the egress data store. Each 128-bit page holds six entries each. Once this register is written, the hardware creates entries in the Buffer Free queue (FQ) at a rate of 6 entries every 150 or 165 ns (rate is dependent on the setting of bit 6 of the DRAM Parameter register - 11/10). The value in this register may be modified during operation. However, the new value may not be smaller than the current value.
Reserved	23:0		Reserved

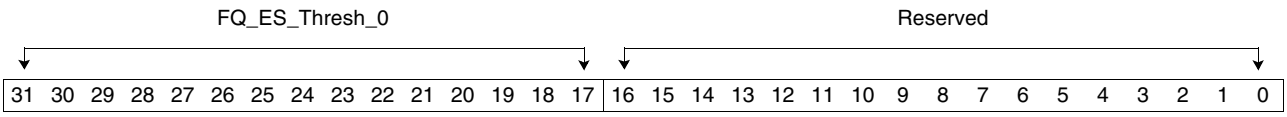
13.18 Egress Free Queue Thresholds

A queue count is maintained by the free queue extended stack management hardware. The count value is continuously compared to the value contained in each of three threshold registers. The result of this comparison affects the NP4GS3's flow control mechanisms. The register values must be chosen such that FQ_ES_Th_0 ≤ FQ_ES_Th_1 ≤ FQ_ES_Th_2.

13.18.1 FQ_ES_Threshold_0 Register (FQ_ES_Th_0)

Access Type Read/Write

Base Address x'A000 2010'

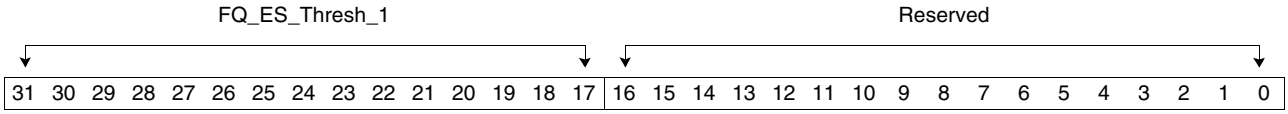


Field Name	Bit(s)	Reset	Description
FQ_ES_Thresh_0	31:17	x'0000'	Free Queue Extended Stack Threshold 0 as measured in units of 16 Twins. When this threshold is violated (the threshold value is greater than the number of remaining twins in the free queue): • Frame data received at the switch interface is discarded (the number of frames discarded is counted). • Frames that have started re-assembly that receive data while this threshold is violated are also discarded (all data associated with the frame is discarded). • Guided traffic data is not discarded. • An interrupt is sent to the EPC.
Reserved	16:0		Reserved

13.18.2 FQ_ES_Threshold_1 Register (FQ_ES_Th_1)

Access Type Read/Write

Base Address x‘A000 2020’

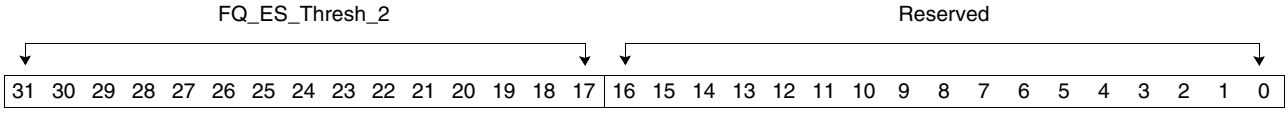


Field Name	Bit(s)	Reset	Description
FQ_ES_Thresh_1	31:17	x‘0000’	Free Queue Extended Stack Threshold 1 as measured in units of 16 Twins. When this threshold is violated (the threshold value is greater than the number of remaining twins in the free queue), an interrupt is sent to the EPC.
Reserved	16:0		Reserved

13.18.3 FQ_ES_Threshold_2 Register (FQ_ES_Th_2)

Access Type Read/Write

Base Address x‘A000 2040’



Field Name	Bit(s)	Reset	Description
FQ_ES_Thresh_2	31:17	x‘0000’	Free Queue Extended Stack Threshold 2 as measured in units of 16 Twins. When this threshold is violated (the threshold value is greater than the number of remaining twins in the free queue), an interrupt is sent to the EPC and, if enabled by DMU configuration, the Ethernet preamble is reduced to 6 bytes
Reserved	16:0		Reserved

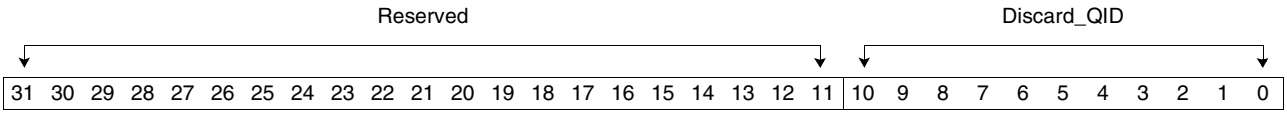
13.19 Discard Flow QCB Register (Discard_QCB)

This register is used by the egress hardware when the scheduler and flow control are enabled. This register contains the address of the flow QCB to be used when egress flow control actions require that the frame be discarded. This register and the QCB referenced by the address must be configured by hardware. See the IBM PowerNP NP4GS3 Databook, Section 6, for details on configuring the QCB.

When the scheduler is disabled, the register contains the target port queue to which the flow control discarded frames are sent. This value should be set to x‘029’.

Access Type Read/Write

Base Address x‘A000 1400’



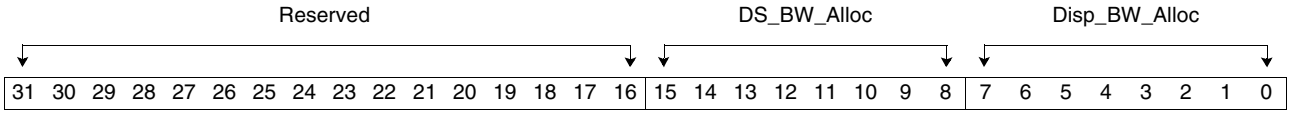
Field Name	Bit(s)	Reset	Description
Reserved	31:11		Reserved
Discard_QID	10:0	x‘029’	The Discard QID field contains the address of the QCB that has been configured for discarding egress frames while the scheduler is enabled. When the scheduler is disabled, this is the target port ID (x‘029’) to which discarded frames due to flow control discard actions are sent.

13.20 Bandwidth Allocation Register (BW_Alloc_Reg, NP4GS3B (R2.0))

The bandwidth allocation register is used to assure bandwidth to the egress datastore for the EPC Datastore coprocessor and the Dispatch Unit. For the EPC Datastore Coprocessor, this register provides assured bandwidth when writing to the egress data store. For the EPC dispatch unit, it provides assured bandwidth when reading the egress data store.

Access Type Read/Write

Base Addresses x'A000 2800'



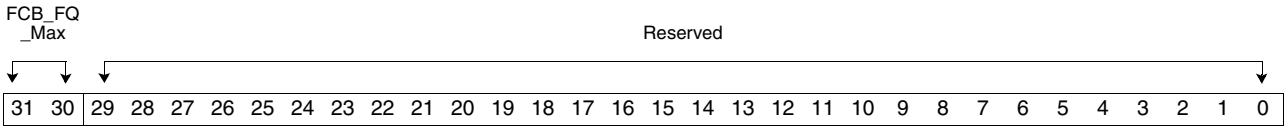
Field Name	Bit(s)	Reset	Description
Reserved	31:16		Reserved
DS_BW_Alloc	15:8	0	Data store coprocessor write BW allocation control value. An 8-bit countdown value. A value of 0 disables this function. This value is loaded into a control register and is decremented each data store access window. While the control register is non-zero, the switch interface has high priority for datastore write access. The EPC data store coprocessor write requests must wait until there is a free window. Once the control register has counted down to 0, the EPC request for the data store write access window has high priority. The control register remains at zero until an EPC data store coprocessor write request is serviced. Whenever an EPC data store write window request is serviced and the configuration register is non-zero, the control register is re-loaded with the configuration value.
Disp_BW_Alloc	7:0	0	Dispatch Unit read BW allocation control value. An 8-bit countdown value. A value of 0 disables this function. The value is loaded into a control registers and is decremented each data store access window. While the control register is non-zero, the following priority is observed for read access to the egress data stores: 8/9th of the time — 1/9th of the time 1. PMM - DMU A-D read requests — PMM - DMU A-D read requests 2. Discard Port — Dispatch Unit Dispatch Unit — EPC Datastore coprocessor read 3. EPC Datastore coprocessor read — Discard Port 4. PMM - Wrap DMU — PMM - Wrap DMU Once the control register decrements to zero, the following priority is observed: 8/9th of the time — 1/9th of the time 1. Dispatch Unit — Dispatch Unit 2. PMM - DMU A-D read requests — PMM - DMU A-D read requests Discard Port — EPC Datastore coprocessor read 3. EPC Datastore coprocessor read — Discard Port 4. PMM - Wrap DMU — PMM - Wrap DMU When the Dispatch Unit is serviced, or a DRAM refresh occurs for DS0/DS1, the control register is re-loaded with the configuration value.

13.21 Frame Control Block FQ Size Register (FCB_FQ_Max)

This register sets the number of Frame control blocks that are released to the FCB FQ during initialization. This register must be set prior to initialization (see *13.7.1 Initialization Register (Init)* on page 451) to affect the FCB FQ size. Any changes after initialization will not affect the number of available FCBs.

Access Type Read/Write

Base Address x'A000 2200'



Field Name	Bit(s)	Reset	Description
FCB_FQ_Max	31:30	00	Indicates the number of FCBs released into the FCB free queue during initialization. 00 128K 01 256K 10 512K 11 Reserved
Reserved	29:0		Reserved

Note: The following settings are recommended based on the size of the D4 DRAM which is configured in the DRAM_Parm register (see *13.1.2 DRAM Parameter Register (DRAM_Parm)* on page 440) bits 2:1.

DRAM_Size	FCB_FQ_Max
00	01
01	10
10	11
11	Reserved

13.22 Data Mover Unit (DMU) Configuration

There are four Data Mover Units (DMU) configured for internal MAC operation, for external connection detection (i.e., attached control point detection), and for external bus operation (i.e., TMII, SMII, TBI, and POS framer).

Access Type	Base Address Offset 0	Read Only
	Base Address Offset 1	Read/Write
	Base Address Offset 2	Read/Write

Base Address Offset 0

Field Name	Bit(s)	Reset	Description
Reserved	31:2		Reserved
In_Reset	1	1	DMU In Reset indicator originates in the clocking logic. 0 Written when the clock logic removes the reset signal for the DMU. 1 DMU is held in reset mode.
CP_Detect	0	0	Control Point Detected indicator value originates in the PMM. 0 Control point processor connection not present 1 DMU detected a Control Point processor connection.

Base Address Offset 1

Field Name	Bit(s)	Reset	Description
Reserved	31:28		Reserved
Framer_AC_Strip	27	0	Configures the MAC operation for an attached POS framer. 0 Framer passes AC field to the network processor 1 Framer does not pass AC field to the network processor. The CRC checking performed is modified to account for the missing field. An AC value of x'FF03' is assumed.
AC_Strip_Ena	26	0	Configures the MAC operation for an attached POS framer. 0 AC field is not stripped from the packet. 1 AC field is stripped from the packet prior to being stored in the ingress data store.
Framer_AC_Insert	25	0	Configures the MAC operation for an attached POS framer. 0 AC field is assumed present in the packet sent to the framer. 1 AC field is not present in the packet sent to the framer. The framer inserts this field and CRC generation is adjusted to account for the missing AC field. An AC value of x'FF03' is assumed.
AC_Insert_Ena	24	1	Configures the MAC operation for an attached POS framer. 0 AC field is not inserted by the MAC. For proper operation, Framer_AC_Insert must be set to 1. 1 AC field is inserted by the MAC. For proper operation, Framer_AC_Insert must be set to 0.
Bus_Delay	23	0	Bus Delay controls the length of the delay between a poll request being made and when the MAC samples the framer's response. 0 Sample is taken 1 cycle after the poll request 1 Sample is taken 2 cycles after the poll request.
CRC_Type_32	22	0	CRC_Type_32 controls the type of frame CRC checking and generation performed in the POS MAC. This field does not control CRC generation for the Ethernet MAC. The Ethernet MAC can generate only 32-bit CRC. 0 16-bit CRC in use. 1 32-bit CRC in use
VLAN_Chk_Dis	21	0	VLAN Checking Disable control value. 0 Enable VLAN checking. 1 Disable VLAN checking by the DMU.
Etype_Chk_Dis	20	0	Ethernet Type Checking Disable control value. 0 Enable DMU checking. 1 Disable DMU checking of E_Type_C and E_Type_D

Field Name	Bit(s)	Reset	Description
Pause_Chk_Dis	19	0	Pause Frame Checking Disable control value. 0 Pause frames are processed by the MAC. They are not sent to the Ingress EDS. 1 Pause frames are not processed by the MAC. The frames are sent to the Ingress EDS for service. See also Honor_Pause in offset 3 for additional control of the MAC in relation to pause frames.
Ignore_CRC	18	0	Ignore CRC controls the behavior of CRC checking for each DMU. 0 Discard frames with bad CRC 1 Ignore bad CRC
Enet_Catchup_Ena	17	1	Ethernet MAC catch up enabled. When enabled and FQ_ES_Threshold_2 is violated, the MAC uses a 6-byte preamble instead of a 7-byte preamble. 0 Disabled 1 Enabled
TX_Thresh	16:14	100	Transmit Threshold configures the number of cell buffers that must be filled before the transmission of a frame can start. 000 Invalid 001-100 Range available for all DMU_Bus_Mode settings 101-111 Range available only for Gigabit Ethernet, POS OC-12, and POS OC-48 DMU_Bus_Mode settings
DM_Bus_Mode	13:10	1010	Data Mover Bus Mode configures the mode in which the DM Bus operates. 0000 Reserved 0001 10/100 Ethernet SMII Mode 0010 Gigabit Ethernet GMII Mode 0011 Gigabit Ethernet TBI Mode 0100 POS OC-12 Mode; non-polling POS support 0101 POS 4xOC-3 mode; polling POS support 0110-1001 Reserved 1010 CP Detect Mode 1011 Debug Mode (DMU D only) 1100-1101 Reserved 1110 DMU Disabled 1111 POS OC-48 Mode; Quad DMU mode, non-polling, POS support. When configuring for this mode of operation, all 4 DMU configuration registers must be set up the same (all bits in all offsets must be identical). **Note:** When configuring the DMU, the DMU_Bus_Mode field must be set first. Subsequent CAB writes can used to configure the remaining fields.
TX_Ena(9:0)	9:0	0	Port Transmit Enable control is a bitwise enable for each port's transmitter. 0 Disable Port 1 Enable Port

Base Address Offset 2

Field Name	Bit(s)	Reset	Description
Reserved	31:30		Reserved
RX_Ena(9:0)	29:20	0	Port Receive Enable control is a bitwise enable for each port's receiver. 0 Disable Port 1 Enable Port

Field Name	Bit(s)	Reset	Description
FDX/HDX(9:0)	19:10	0	Full Duplex or Half Duplex operation mode for ports 9 to 0 controls the mode of operation for the associated port. 0 Half Duplex (HDX) operation 1 Full Duplex (FDX) operation
Jumbo(9:0)	9:0	0	Jumbo frame operation mode for ports 9 to 0 controls the mode of operation for the associated port. 0 Jumbo Frames Disabled 1 Jumbo Frames Enabled

Base Address Offset 3

Field Name	Bit(s)	Reset	Description
Reserved	31:10		Reserved
Honor_Pause(9:0)	9:0	0	Honor Pause control value is a bitwise control value for the port's pause function. 0 Ignore pause frames received by corresponding port 1 Pause when pause frame received by corresponding port

13.23 QD Accuracy Register (QD_Acc)

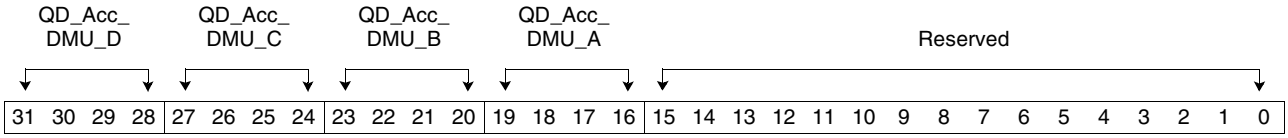
The QD Accuracy register tunes the egress scheduler's WFQ rings. The values assure fairness and some benefit to queues with lower defined QD values which expect better service when enqueueing to an empty queue. The value is also a scaling factor when servicing queues. Configuration recommendations are dependent on the maximum frame sizes expected for a DMU.

Max Frame size	QD_Acc_DMU
2 K	6
9 K	8
14 K	10

There is one field defined per media DMU (A-D).

Access Type Read/Write

Base Address x'A002 4000'



Field Name	Bit(s)	Reset	Description
QD_Acc_DMU_D	31:28	0	QD Accuracy value used for DMU_D
QD_Acc_DMU_C	27:24	0	QD Accuracy value used for DMU_C
QD_Acc_DMU_B	23:20	0	QD Accuracy value used for DMU_B
QD_Acc_DMU_A	19:16	0	QD Accuracy value used for DMU_A
Reserved	15:0		Reserved

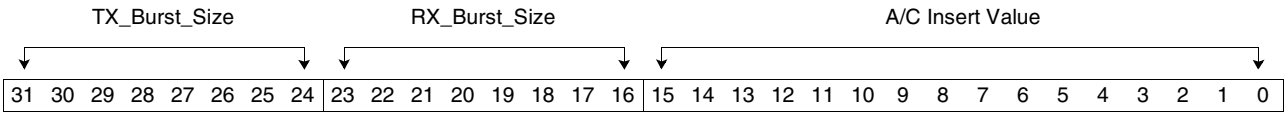
13.24 Packet Over SONET Control Register (POS_Ctrl)

One configuration register per DMU is provided to control POS framer interaction. It configures transmit and receive burst sizes and sets the value used for AC field insertion.

Access Type Read/Write

Base Address

DMU_A	x‘A004 0100’
DMU_B	x‘A004 0200’
DMU_C	x‘A004 0400’
DMU_D	x‘A004 0800’



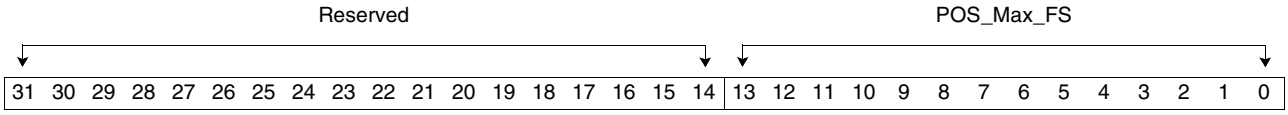
Field Name	Bit(s)	Reset	Description
TX_Burst_Size	31:24	x'10'	Transmit burst size. Used only for OC-3 modes of operation. OC-12 and OC-48 interfaces transmit until the framer de-asserts TxPFA. When set to 0 the MAC uses TxPFA from the frame to stop transmission of data. When set to a value other than 0, the MAC will burst data to the framer up to the burst size or until the framer drops TxPFA. It is recommended that the low water mark in the frame be set to a value equal to or greater than the value of Tx_Burst_Size.
RX_Burst_Size	23:16	x'10'	Receive burst size
A/C Insert Value	15:0	x'FF03'	Value used by the MAC when AC_Insert_Ena is set to 1

13.25 Packet Over SONET Maximum Frame Size (POS_Max_FS)

This register controls the maximum frame size supported by the network processor. POS permits frames up to 64 K bytes, however, the network processor is constrained to 14 K (14336) bytes maximum. This register allows setting for smaller frame sizes. Frames received by the network processor that exceed the length specified by this register are aborted during reception.

Access Type Read/Write

Base Address x‘A004 0080’



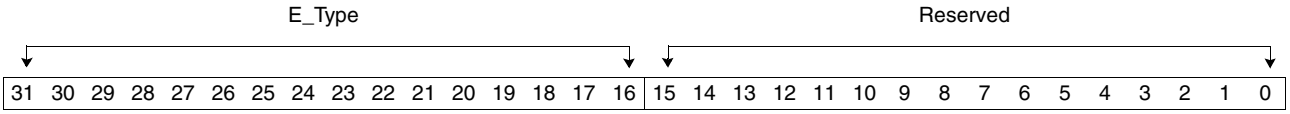
Field Name	Bit(s)	Reset	Description
Reserved	31:14		Reserved
POS_Max_FS	13:0	x‘3800’	Packet over SONET Maximum Frame Size sets the maximum frame size that the network processor can receive on a POS port. The value in this register is used to determine the length of a long frame for the ingress and egress Long Frame counters.

13.26 Ethernet Encapsulation Type Register for Control (E_Type_C)

This configuration register is used by the PMM to recognize Ethernet-encapsulated guided frames. When the Ethernet frame's type field matches this value, the MAC DA, SA, and Type fields of the frame are stripped and the frame is queued onto the GFQ.

Access Type Read/Write

Base Addresses x'A001 1000'



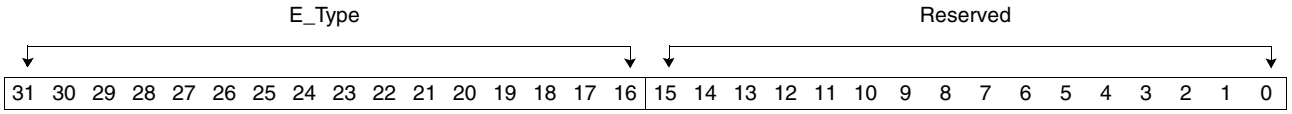
Field Name	Bit(s)	Reset	Description
E_Type	31:16	x'0000'	Ethernet Type used for encapsulated guided traffic.
Reserved	15:0		Reserved

13.27 Ethernet Encapsulation Type Register for Data (E_Type_D)

This configuration register is used by the PMM to recognize Ethernet-encapsulated data frames. When the Ethernet frame's type field matches this value, the MAC DA, SA, and Type fields of the frame are stripped and the frame is queued onto the GDQ.

Access Type Read/Write

Base Addresses x'A001 2000'



Field Name	Bit(s)	Reset	Description
E_Type	31:16	x'0000'	Ethernet Type used for encapsulated CP data traffic.
Reserved	15:0		Reserved

13.28 Source Address Array (SA_Array)

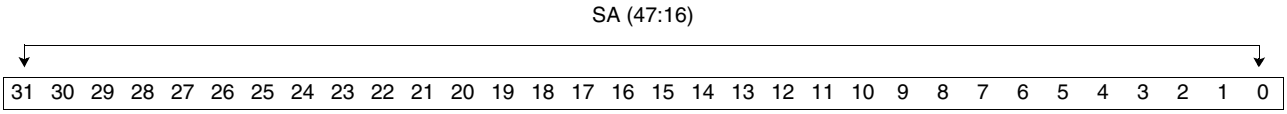
The SA Array is a register array containing 64 Source Address values. The SA Pointer from the egress FCB references elements of this register array. The value retrieved from the SA Array is used to insert or overlay the SA field of transmitted frames during egress frame alteration.

Access Type Read/Write

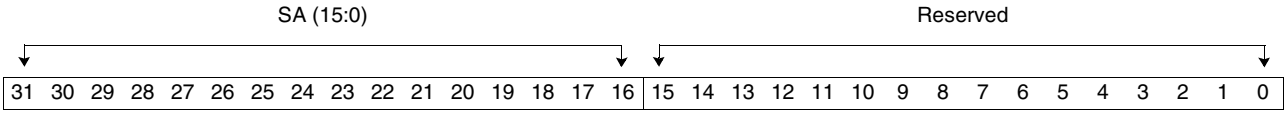
Base Addresses Note: Each DMU listed below contains 64 entries. Nibbles 5 and 6 of the base address is incremented by x'01' for each successive entry, represented by '##', and ranging from x'00' to x'3F'. The word offset is represented by 'W', and ranges from x'0' to x'1'.

DMU_A	x'8810 0##W'
DMU_B	x'8811 0##W'
DMU_C	x'8812 0##W'
DMU_D	x'8813 0##W'
Wrap	x'8814 0##W'

Base Address Offset 0



Base Address Offset 1



Base Address Offset 0

Field Name	Bit(s)	Reset	Description
SA(47:16)	31:0	Not defined	Source Address value. The DMU accesses an SA value when it performs egress frame alteration functions. The data is the source address that is either overlaid or inserted into a frame. The entry address is inferred from the contents of the FCB.

Base Address Offset 1

Field Name	Bit(s)	Reset	Description
SA(15:0)	31:16	Not defined	Source Address value. The DMU accesses an SA value when it performs egress frame alteration functions. The data is the source address that is either overlaid or inserted into a frame. The entry address is inferred from the contents of the FCB.
Reserved	15:0		Reserved

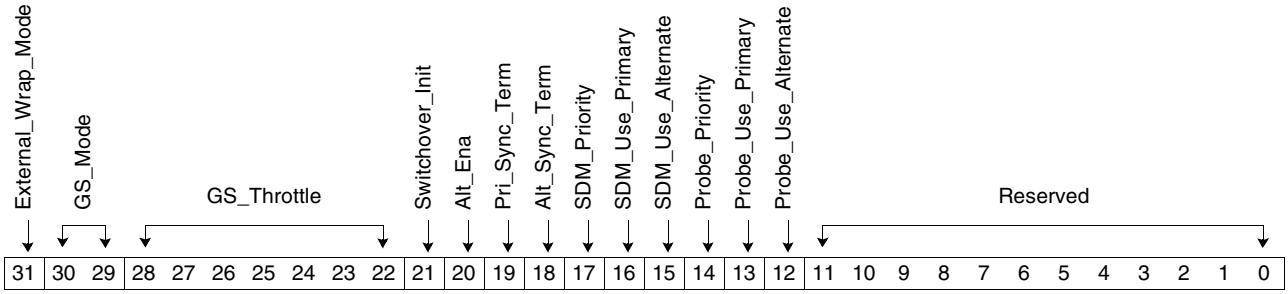
13.29 DASL Initialization and Configuration

13.29.1 DASL Configuration Register (DASL_Config)

This register contains control information for the DASL-A and DASL-B interfaces.

Access Type Read/Write

Base Address x'A000 0110'



Field Name	Bit(s)	Reset	Description
External_Wrap_Mode	31	0	External Wrap Mode indicator value. 0 The network processor is configured for DASL connection to one or two switches supporting up to 64 target blades. 1 The network processor is configured for external DASL wrap connections. One or two network processors can be supported in this mode, restricting target blade addressing to the values of 0 or 1.
GS_Mode	30:29	01	Grant Status Mode controls the setting of and response to grant status by a functional unit. 00 Reserved. 01 Deassert Grant Status when E-SDM is Full. 10 Deassert Grant Status one out of every N+1 times, where the value N is contained in the GS Throttle field. 11 Reserved.
GS_Throttle	28:22	x'00'	Grant Status Throttle When GS Mode is set to '10', GS throttle controls the rate at which Grant Status is deasserted. That rate is once every "GS_Throttle + 1" cell times.
Switchover_Init	21	0	Switchover Initialization 0 Nop 1 Switchover Initialization re-starts the Primary DASL interface (normal use is in response to a switchover event).
Alt_Ena	20	0	Alternate DASL Enable control flag. 0 Nop 1 Set by SWI to enable the Alternate DASL Port. Then the SWI starts sending Sync Cells and the receiver searches the attain synchronization with the incoming serial stream.
Pri_Sync_Term	19	0	Primary DASL Synchronization Termination 0 Nop 1 Stops the NP4GS3's primary DASL interface from sending the synchronization pattern that completes the DASL synchronization sequence on the primary DASL interface.

Field Name	Bit(s)	Reset	Description
Alt_Sync_Term	18	0	Alternate DASL Synchronization Termination 0 Nop 1 Stops the NP4GS3's alternate DASL interface from sending the synchronization pattern that completes the DASL synchronization sequence on the alternate DASL interface.
SDM_Priority	17	1	I-SDM Priority configures the arbitration priority of I-SDM accesses to the DASL interface. 0 High priority 1 Low priority
SDM Use Primary	16	1	SDM Use Primary 0 Nop 1 Configures the I-SDM traffic to use the primary DASL interface.
SDM_Use_Alternate	15	0	SDM Use Alternate 0 Nop 1 Configures the I-SDM traffic to use the alternate DASL interface.
Probe_Priority	14	0	Probe_Priority configures the arbitration priority of the Probe accesses to the DASL interface. 0 High priority 1 Low priority
Probe_Use_Primary	13	0	Probe Use Primary 0 Nop 1 Configures the Probe traffic to use the primary DASL interface.
Probe_Use_Alternate	12	1	Probe Use Alternate 0 Nop 1 Configures the Probe traffic to use the alternate DASL interface.
Reserved	11:0		Reserved

13.29.1.1 Dynamic Switch Interface Selection

The DASL configuration register uses designations such as primary and alternate. These designations refer to the use of one of the DASL interfaces A or B. The correspondence of primary or alternate to a DASL interface changes based on the value of the Switch_BnA signal IO as shown in the following table:

Switch_BnA	Primary DASL	Alternate DASL
0	DASL A	DASL B
1	DASL B	DASL A

Selection of DASL interface occurs on a frame by frame basis for frames from either the internal I-SDM interface or the internal Probe interface (NP4GS3 datasheet, section 5). Three configuration bits and two calculated bits are used for this determination. The three configuration bits are:

- xxx_Use_Primary Configuration bits 16 and 13 (I-SDM and Probe) of the DASL Configuration register
- xxx_Use Alternate Configuration bits 15 and 12 (I-SDM and Probe) of the DASL Configuration register
- Alt_enabled Configuration bit 20 of the DASL Configuration register

where xxx designates either the SDM or the Probe.

The calculated bits, Local TB and Remote TB, are the result of comparing the Local TB vector (all frames in 16 blade mode and unicast frames for 64 blade modes) and the Local MC Target Blade Vector (for multicast frames when in 64 blade mode) with the TB field of the FCB for the frame that is being transmitted towards the switch interface.

For 16 blade mode when the bit location of a 1 in the TB field matches a 1 in the same bit location in the Local TB vector, or for 64 blade mode when the bit position corresponding to the encoded value in the TB field is a 1 in the Local TB vector, or for 64 blade mode when the value is smaller than the value in the Local MC Target Blade Vector, a Local TB is indicated and the Local TB bit is set to 1.

For 16 blade mode when the bit location of a 1 in the TB field matches a 0 in the same bit location in the Local TB vector or for 64 blade mode when the bit position corresponding to the encoded value in the TB field is a 0 in the Local TB vector, or for 64 blade mode when the value is larger than or equal to the value in the Local MC Target Blade Vector, a Remote TB is indicated and the Remote TB bit is set to 1.

Note that these are mutually exclusive in 64 blade mode. However, in 16 blade mode, both local and remote can be 1 or 0 at the same time.

The following table defines the actions taken for all combinations for these inputs.

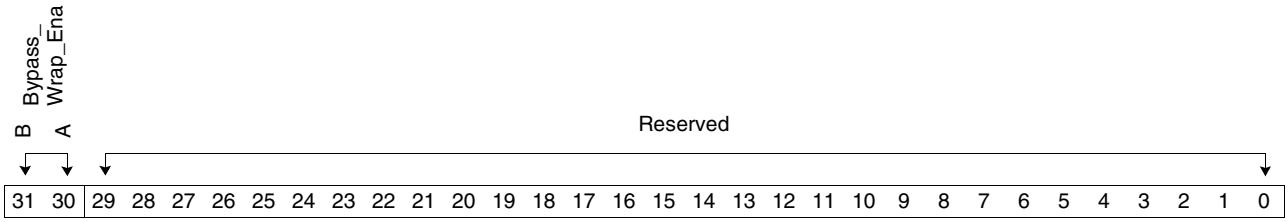
Alt_enabled	Use Primary	Use Alternate	Local TB	Remote TB	Destination Selected
0	-	-	-	-	Primary
1	1	1	-	-	Both
1	-	-	1	1	Both
1	-	0	0	-	Primary
1	-	0	1	0	Alternate
1	0	1	0	-	Alternate
1	0	1	1	0	Primary

13.29.2 DASL Bypass and Wrap Register (DASL_Bypass_Wrap)

This register controls the internal wrap path which bypasses the DASL interface.

Access Type Read/Write

Base Address x‘A002 0080’



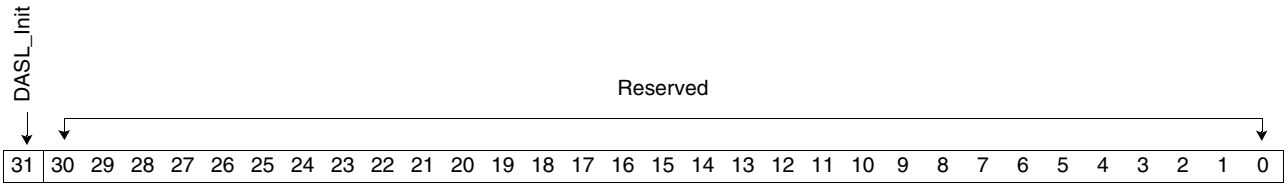
Field Name	Bit(s)	Reset	Description
Bypass_Wrap_Ena	31:30	00	DASL bypass and wrap control enables or disables the DASL bypass and internal wrap path. Bit 31 controls the wrap for the DASL-B interface. Bit 30 controls the wrap for the DASL-A interface. 0 Wrap disabled 1 Wrap enabled
Reserved	29:0		Reserved

13.29.3 DASL Start Register (DASL_Start)

This configuration register initializes the DASL interfaces when the DASL_Init field makes a transition from '0' to '1'. The completion of DASL initialization is reported in the Init_Done Register.

Access Type Read/Write

Base Address x'A000 0210'



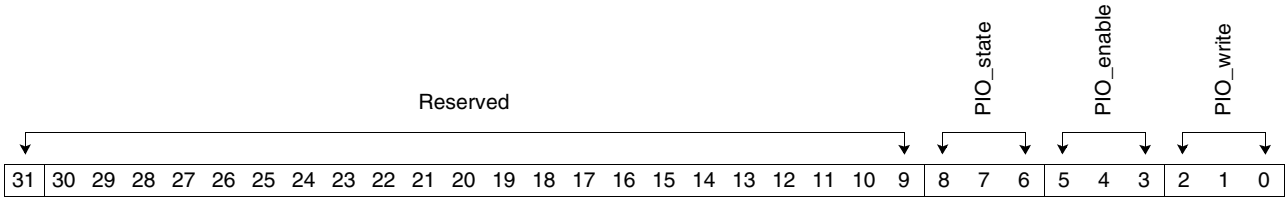
Field Name	Bit(s)	Reset	Description
DASL_Init	31	0	DASL initialization control value. Switching this value from '0' to '1' causes the DASL interfaces to initialize.
Reserved	30:0		Reserved

13.30 Programmable I/O Register (PIO_Reg) (NP4GS3B (R2.0))

This configuration register provides the control for the PIO signal pins (see NP4GS3 Datasheet section 2.1.9, Miscellaneous Pins).

Access Type Read/Write

Base Address x'A040 4000'



Field Name	Bit(s)	Reset	Description
Reserved	30:9		Reserved
PIO_state	8:6		Current value on the PIO(2:0) signal pins. PIO signal pin mapping to register bits is: bit PIO 8 PIO(2) 7 PIO(1) 6 PIO(0)
PIO_enable	5:3		Controls PIO(2:0) driver state. Control values are: 0 Driver is in tristate 1 Driver is enabled. PIO signal pin mapping to register bits is: bit PIO 5 PIO(2) 4 PIO(1) 3 PIO(0)
PIO_write	2:0		Value to be driven onto PIO(2:0) signal pins when the corresponding driver is enabled. PIO signal pin mapping to register bits is: bit PIO 2 PIO(2) 1 PIO(1) 0 PIO(0)

14. Electrical and Thermal Specifications

The NP4GS3 utilizes IBM CMOS SA-27E technology.

Table 14-1. Absolute Maximum Ratings

Symbol	Parameter	Rating	Units	Notes
		1.8 V		
V_{DD}	Power Supply Voltage	1.95	V	1
T_A	Operating Temperature (ambient)	-40 to +100	°C	1
T_J	Junction Temperature	-40 to +125	°C	1
T_{STG}	Storage Temperature	-65 to +150	°C	1

1. Stresses greater than those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Table 14-2. Input Capacitance (pF) (Page 1 of 21) (T_A = 25°C, f = 1 MHz, V_{DD} = 3.3 V ± 0.3 V)

Table 14-3. Operating Supply Voltages

Symbol	Parameter	Rating			Units	Notes
		Min	Typ	Max		
V_{DD25} V_{DD3} V_{DD4} V_{DD5}	2.5 V Power supply	2.375	2.5	2.625	V	1
V_{DD33} V_{DD2}	3.3 V Power supply	3.135	3.3	3.465	V	1
V_{DD}	1.8 V Power supply	1.71	1.8	1.89	V	1
PLLA_V_{DD} PLLB_V_{DD} PLLC_V_{DD}	PLL voltage reference	1.71	1.8	1.89	V	1, 2
$V_{REF1(2-0)}$ $V_{REF2(8-0)}$	SSTL2 Power supply (used for SSTL2 I/O)	1.1875	1.25	1.3125	V	1

1. Important power sequencing requirements: (the following conditions must be met at all times, including power-up and power-down:
   V_{REF}*(1.25 V reference) ≤ V_{DD25} +0.4 V
   PLL*_V_{DD}(2.5 V reference) ≤ V_{DD33} +0.4 V
   V_{DD18} ≤ V_{DD25} + 0.4 V
   V_{DD25} ≤ V_{DD33} + 0.4 V
   V_{DD33} ≤ V_{DD25} + 1.9 V
2. See also *PLL Filter Circuit* on page 80.

Table 14-4. Thermal Characteristics

Thermal Characteristic	Min	Nominal	Max	Units	Notes
Estimated power dissipation		10.67	13	W	NP4GS3 R1.1
Operating junction temperature (Tj)	0		105	°C	1

1. Operation up to T_j = 125°C is supported for up to 3600 hours. However, the electromigration (EM) limit must not exceed 105°C for 88 KPOH equivalent. Contact your IBM field applications engineer for EM equivalents.

14.1 Driver Specifications

Table 14-5. Definition of Terms

Term	Definition
MAUL	Maximum allowable up level. The maximum voltage that can be applied without affecting the specified reliability. Cell functionality is not implied. Maximum allowable applies to overshoot only.
MPUL	Maximum positive up level. The most positive voltage that maintains cell functionality. The maximum positive logic level.
LPUL	Least positive up level. The least positive voltage that maintains cell functionality. The minimum positive logic level.
MPDL	Most positive down level. The most positive voltage that maintains cell functionality. The maximum negative logic level.
LPDL	Least positive down level. The least positive voltage that maintains cell functionality. The minimum negative logic level.
MADL	Minimum allowable down level. The minimum voltage that can be applied without affecting the specified reliability. Minimum allowable applies to undershoot only. Cell functionality is not implied.

Table 14-6. 1.8 V CMOS Driver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
CMOS	V_{DD}[3] + 0.45	V_{DD}[3]	V_{DD}[3] - 0.45	0.45	0.00	-0.60

1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.
3. V_{DD} ranges as specified in *Table 14-3* (Typical = 1.8 V).

Table 14-7. 1.8 V CMOS Driver Minimum DC Currents at Rated Voltage V_{DD} = 1.65 V, T = 100°C

Driver Type	V_{HIGH} (V)	I_{HIGH} (mA)	V_{LOW} (V)	I_{LOW} (mA)
CMOS 50 ohm driver outputs	1.2	8.0/23.0[1]	0.45	7.8[1]

1. 23 mA is the electromigration limit for 100K power on hours (POH) = 100°C and 100% duty cycle. This limit can be adjusted for different temperature, duty cycle, and POH. Consult your IBM application engineer for further details.

Table 14-8. 2.5 V CMOS Driver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
CMOS	V_{DD}[3] + 0.6	V_{DD}[3]	2.0	0.4	0.00	-0.60

1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.
3. V_{DD} ranges as specified in *Table 14-3* (Typical = 2.5 V).

Table 14-9. 2.5 V CMOS Driver Minimum DC Currents at Rated Voltage V_{DD} = 2.3 V, T = 100°C

Driver Type	V_{HIGH} (V)	I_{HIGH} (mA)	V_{LOW} (V)	I_{LOW} (mA)
CMOS 50 ohm driver outputs	2.0	5.2/23[1]	0.4	6.9[1]

1. 23 mA is the electromigration limit for 100K power on hours (POH) = 100°C and 100% duty cycle. This limit can be adjusted for different temperature, duty cycle, and POH. Consult your IBM application engineer for further details.

Table 14-10. 3.3 V-Tolerant 2.5 V CMOS Driver DC Voltage Specifications (see note 1)

Function	MAUL (V)[2]	MPUL (V)[3]	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[4]
LVTTL	3.9	V_{DD}[5]	2.0	0.4	0.00	-0.60

1. All levels adhere to the JEDEC Standard JESD12-6, “Interface Standard for Semi-Custom Integrated Circuits,” March 1991.
2. Maximum allowable applies to overshoot only. Output disabled.
3. Output active.
4. Minimum allowable applies to undershoot only.
5. V_{DD} ranges as specified in *Table 14-3* (Typical = 2.5 V).

Table 14-11. 3.3 V LVTTL Driver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
LVTTL	V_{DD330}[3] + 0.3	V_{DD330}[3]	2.4	0.4	0.00	-0.60

1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.
3. $V_{DD\ 33}$ ranges as specified in *Table 14-3* (Typical = 3.3 V).

Table 14-12. 3.3 V LVTTL/5.0 V-Tolerant Driver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
LVTTL	V_{DD330}[3] + 0.3	V_{DD330}[3]	2.4	0.4	0.00	-0.60

1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.
3. $V_{DD\ 33}$ ranges as specified in *Table 14-3* (Typical = 3.3 V).

Table 14-13. 3.3 V LVTTL Driver Minimum DC Currents at Rated Voltage (V_{DD} = 3.0 V, T = 100°C)

Driver Type	V_{HIGH} (V)	I_{HIGH} (mA)	V_{LOW} (V)	I_{LOW} (mA)
LVTTL 50 ohm driver outputs	2.40	10.3/23[1]	0.4	7.1[1]

1. 23 mA is the electromigration limit for 100K power on hours (POH) = 100°C and 100% duty cycle. This limit can be adjusted for different temperature, duty cycle, and POH. Consult your IBM application engineer for further details.

14.2 Receiver Specifications

Table 14-14. 1.8 V CMOS Receiver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
CMOS	V_{DD}[3] + 0.45	V_{DD}[3]	0.65 V_{DD}[3]	0.35 V_{DD}[3]	0.00	-0.60

1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.
3. V_{DD} ranges as specified in *Table 14-3* (Typical = 1.8 V).

Table 14-15. 2.5 V CMOS Receiver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
CMOS	V_{DD}[3] + 0.6	V_{DD}	1.7	0.70	0.00	-0.60

1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.
3. V_{DD} ranges as specified in *Table 14-3* (Typical = 2.5 V).

Table 14-16. 3.3 V LVTTL Receiver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
LVTTL	V_{DD330}[3]+ 0.3	V_{DD330}[3]	2.00	0.80	0.00	-0.60

1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.
3. $V_{DD\ 33}$ ranges as specified in *Table 14-3* (Typical = 3.3 V).

Table 14-17. 3.3 V LVTTL / 5 V Tolerant Receiver DC Voltage Specifications

Function	MAUL (V)[1]	MPUL (V)	LPUL (V)	MPDL (V)	LPDL (V)	MADL (V)[2]
LVTTL	5.5 V	5.5 V	2.00	0.80	0.00	-0.60

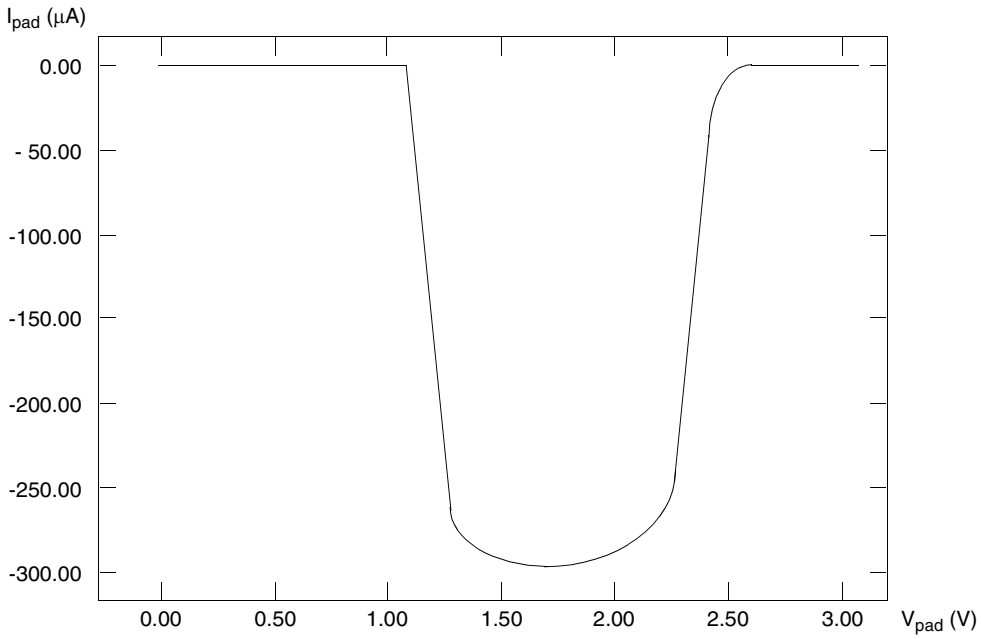
1. Maximum allowable applies to overshoot only.
2. Minimum allowable applies to undershoot only.

Table 14-18. Receiver Maximum Input Leakage DC Current Input Specifications

Function	I_{IL} (µA)	I_{IH} (µA)
Without pull-up element or pull-down element	0 at V_{IN} = LPDL	0 at V_{IN} = MPUL
With pull-down element	0 at V_{IN} = LPDL	200 at V_{IN} = MPUL
With pull-up element	-150 at V_{IN} = LPDL	0 at V_{IN} = MPUL

1. See section *3.3 V LVTTL / 5 V Tolerant BP33 and IP33 Receiver Input Current/Voltage Curve on page 534.*

Figure 14-1. 3.3 V LVTTL / 5 V Tolerant BP33 and IP33 Receiver Input Current/Voltage Curve



1. Curve shows best case process - 0°C, 3.6V

14.3 Other Driver and Receiver Specifications

Table 14-19. LVDS Receiver DC Specifications

Symbol	Parameter	Min	Nom	Max	Units	Comments
V_{DD}	Device supply voltage	1.65	1.8	1.95	V	Receiver uses only V_{DD} supply.
Temp	Temperature Range	0	50	100	°C	
Rec Pwr	Input buffer power			9.3	mW	Including on-chip terminator V_{PAD} - V_{PADN} = 0.4 V
V_{IH}	Receiver input voltage			V_{DD} + 0.20	V	Receiver ESD connected to V_{DD}
V_{IL}	Receiver input voltage	-0.20			V	
V_{IH} - V_{IL}	Receiver input voltage range	100			mV	@600 MHz
V_{ICM}	Receiver common mode range	0	1.25	V_{DD}	V	
Ri	Input impedance	80		100		120Ω

Notes:

1. All DC characteristics are based on power supply and temperature ranges as specified above.
2. This receiver using a V_{DD} of 1.8 V nominal is compatible with the 1.5 V specification described in the LVDS standard: IEEE Standard for Low-Voltage Differential Signals (LVDS) for Scalable Coherent Interface (SCI), IEEE Standard 1596.3,1996.
3. Maximum frequency is load and package dependent. 600 MHz (1.2 Gbps) is achievable with a minimum of 100 mV input swing over the wide common range as specified. The customer is responsible for determining optimal frequency and switching capabilities through thorough simulation and analysis.

Table 14-20. SSTL2 DC Specifications

Symbol	Parameter	Min	Nom	Max	Units	Comments
V_{DD}	Device supply voltage	1.65	1.8	1.95	V	
V_{DDQ}	Output supply voltage	2.3	2.5	2.7	V	$V_{DDQ} = V_{DD250}$
V_{TT}	Termination voltage	1.11 - 1.19	1.25	1.31 - 1.39	V	$0.5*V_{DDQ}$
V_{REF}	Differential input reference voltage	1.15	1.25	1.35	V	$0.5*V_{DDQ}$
V_{OH} (Class II)	Output high voltage	1.95			V	I_{OH} = 15.2 mA @ 1.95 V
V_{OL} (Class II)	Output low voltage			0.55	V	I_{OL} = 15.2 mA @ 0.55 V
R_{OH} max (Class II)	Max pull-up impedance			36.2	Ω	

Notes:

1. All SSTL2 specifications are consistent with JEDEC committee re-ballot (JC-16-97-58A), 10/14/97.
2. Di/dt and performance are chosen by performance level selection (A and B).
   a. Performance level A is targeted to run at 200 MHz or faster depending on loading conditions. Di/dt is comparable to 110 mA/ns 2.5 V/3.3 V LVTTL driver.
   b. Performance level B is targeted to run at 250 MHz or faster depending on loading conditions. Di/dt is comparable to 150 mA/ns 2.5 V/3.3 V LVTTL driver.
3. The differential input reference supply (V_{REF}) is brought on chip through VSSTL2R1 and VSSTL2R2 I/O cells.
4. Termination voltage (V_{TT}) is generated off-chip.
5. SSTL2 driver is rated at 20 mA @100°C and 50% duty cycle for 100k power on hours (POH).

Table 14-20. SSTL2 DC Specifications

Symbol	Parameter	Min	Nom	Max	Units	Comments
R_{OL} max (Class II)	Max pull-down impedance			36.2	Ω	
V_{IH}	Input high voltage	V_{REF} + 0.18		V_{DDQ} + 0.3	V	
V_{IL}	Input low voltage	-0.3		V_{REF} - 0.18	V	
I_{OZ}	3-state leakage current	0		10	µA	Driver Hi-Z
Temp	Temperature	0	50	100	°C	

Notes:

1. All SSTL2 specifications are consistent with JEDEC committee re-ballot (JC-16-97-58A), 10/14/97.
2. Di/dt and performance are chosen by performance level selection (A and B).
   a. Performance level A is targeted to run at 200 MHz or faster depending on loading conditions. Di/dt is comparable to 110 mA/ns 2.5 V/3.3 V LVTTL driver.
   b. Performance level B is targeted to run at 250 MHz or faster depending on loading conditions. Di/dt is comparable to 150 mA/ns 2.5 V/3.3 V LVTTL driver.
3. The differential input reference supply (V_{REF}) is brought on chip through VSSTL2R1 and VSSTL2R2 I/O cells.
4. Termination voltage (V_{TT}) is generated off-chip.
5. SSTL2 driver is rated at 20 mA @100°C and 50% duty cycle for 100k power on hours (POH).

14.3.1 DASL Specifications

Table 14-21. DASL Receiver DC Specifications IDASL_A

Symbol	Parameter	Min	Nom	Max	Units	Comments
V_{DD}	Device supply voltage	1.7	1.8	1.9	V	Receiver uses only V_{DD} supply
Temp	Temperature range	0	50	100	°C	Functional at 125°C with EM degradation
Rec Pwr	Input buffer power			4.5	mW	Including on-chip pull-downs for PAD and PADN.
V_{IH}	Receiver input voltage			V_{DD} + 0.20	V	Receiver ESD connected to V_{DD}
V_{IL}	Receiver input voltage	-0.20			V	ZLOS starts to activate when PAD and PADN go below 0.6 V
V_{IH} - V_{IL}	Receiver input voltage range	200			mV	
V_{ICM}	Receiver common mode range	0.60	0.90	$V_{DD - 0.4}$	V	

Design Notes:

1. All DC characteristics are based on power supply and temperature ranges as specified above.

Table 14-22. DASL Driver DC Specifications ODASL_A

Symbol	Parameter	Min	Nom	Max	Units	Comments
V_{DD}	Device supply voltage	1.7	1.8	1.9	V	Driver uses only V_{DD} supply
Temp	Temperature range	0	50	100	°C	Functional at 125°C with EM degradation
V_{OH}	Output voltage high	1.25	1.35	1.45	V	Board termination of 50 Ω to $V_{DD}/2$
V_{OL}	Output voltage low	0.39	0.42	0.45	V	Board termination of 50 Ω to $V_{DD}/2$
$\|V_{OD}\|$	Output differential voltage	0.80	0.93	1.06	V	V_{OH} - V_{OL}
V_{OS}	Output offset voltage	0.82	0.89	0.95	V	$(V_{OH} + V_{OL})/2$
R_O	Output impedance, single-ended	42		52	Ω	Design assumes 3 Ω for package resistance to achieve 50 Ω nominal.
I_{load}	Terminator current	0.80	0.90	10.5	mA	Board termination
Drv Pwr	Output buffer power			17.5	mW	Excluding termination
Drv Pwr (Hi-Z mode)	Output buffer power in Hi-Z mode			2	mW	

Design Notes:

1. All DC characteristics are based on power supply and temperature ranges as specified above and using board termination of 100 Ω with approximately ± 5% tolerance over supply and temperature.
2. Maximum frequency is load and package dependent. Operation of 625 Mbps is achievable over a reasonable length of PCB or cable. The customer is responsible for determining optimal frequency and switching capabilities through thorough simulation and analysis using appropriate package and transmission line models.

15. Glossary of Terms and Abbreviations

Term	Definition
ALU	arithmetic and logic unit
API	application programming interface
ARB	arbitration
ARDL	advance rope with optional delete leaf
ARP	Address Resolution Protocol
ATH	actual threshold
BCB	buffer control block
BCI	byte count information
BEB	binary exponential back-off
BFQ	Buffer Free Queue
BGP	Border Gateway Protocol
bird	An intermediate leaf. It occurs when the PSCBLine contains an intermediate LCBA pointing to this leaf and an NPA pointing to the next PSCB.
BL	burst length
blade	Any I/O card that can be inserted in a modular chassis (also called line card).
BSM-CCGA	bottom surface metallurgy - ceramic column grid array
byte	8 bits
CAB	Control Access Bus
CBA	control block address
CHAP	Challenge-Handshake Authentication Protocol
CIA	Common Instruction Address
CLNS	connectionless-mode network service
CLP	See Core Language Processor.
Core Language Processor (CLP)	The picoprocessor core, also referred to as coprocessor 0. The CLP executes the base instruction set and controls thread swapping and instruction fetching.
CP	control point
CPF	control point function
CPIX	Common Programming Interface

Term	Definition
CRC	See *cyclic redundancy check.*
CS	Control Store
CSA	Control Store Arbiter
cyclic redundancy check (CRC)	A system of error checking performed at both the sending and receiving station after a block-check character has been accumulated.
DA	destination address
DASL	data-aligned synchronous link
data store	In the Network Processor, the place where a frame is stored while waiting for processing or forwarding to its destination.
DBGS	Debug Services
DDR	double data rate
DiffServ	Differentiated Services
Distinguishing Position (DISTPOS)	The index value of a first mismatch bit between the input key and the reference key found in a leaf pattern
DISTPOS	See *Distinguishing Position (DISTPOS).*
DLQ	Discard List Queue
DMU	Data Mover Unit
doubleword	2 words
DPPU	dyadic protocol processor unit
DQ	Discard Queue
DRAM	dynamic random-access memory
DS	See *data store.*
DSCP	DiffServ code point
DSI	Distributed Software Interface
DT	Direct Table
DVMRP	Distance Vector Multicast Routing Protocol
E-	Egress
ECC	Error correcting code
ECMP	equal-cost multipath

Term	Definition
EDS	Enqueuer / Dequeuer / Scheduler
E-DS	Egress Data Store
E-GDQ	Discard Queue Stack. Holds frames that need to be discarded. This is used by the hardware to discard frames when the egress DS is congested or to re-walk a frame marked for discard for a half duplex port. Used by the picocode to discard frames that do not have header twins allocated.
Egress EDS	Egress Enqueuer / Dequeuer / Scheduler
Enet MAC	Ethernet MAC
EOF	end-of-frame
EPC	Embedded Processor Complex
E-PMM	Egress-Physical MAC Multiplexer
even parity	Data checking method where a parity bit is added to a data field. Even parity is achieved when the number of bits (data + parity) that contain a '1' is even.
EWMA	exponentially weighted moving average
exponentially weighted average	See *exponentially weighted moving average.*
exponentially weighted moving average	A method of smoothing a sequence of instantaneous measurements. Typically, the average A(t) at time t is combined with the measurement M(t) at time t to yield the next average value: $A(t + Dt) = W * M(t) + (1 - W) * A(t)$ Here weight W is a number with $0 < W \pm 1$. If the weight is 1, then the average is just the previous value of the measurement and no smoothing occurs. Else previous values of M contribute to the current value of A with more recent M values being more influential.
FCB	frame control block
FFA	flexible frame alternation
FHE	frame header extension
FHF	Frame Header Format
FM	full match
FPGA	field-programmable gate array
FTA	first twin-buffer address
GDH	See *General Data Handler*.

Term	Definition
General Data Handler (GDH)	A type of thread used to forward frames in the EPC. There are 28 GDH threads.
General PowerPC Handler Request (GPH-Req)	A type of thread in the EPC that processes frames bound to the embedded PowerPC. Work for this thread is usually the result of a reenqueue action to the PPC queue (it processes data frames when there are no entries to process in the PPC queue).
General PowerPC Handler Response (GPH-Resp)	A type of thread in the EPC that processes responses from the embedded PowerPC. Work for this thread is dispatched due to an interrupt and does not use dispatcher memory.
General Table Handler (GTH)	The GTH executes commands not available to a GDH or GFH thread, including hardware assist to perform tree inserts, tree deletes, tree aging, and rope management. It processes data frames when there are no tree management functions to perform.
GFH	See *Guided Frame Handler*.
GFQ	Guided Frame Queue
GMII	Gigabit Media-Independent Interface
GPH-Req	See *General PowerPC Handler Request*.
GPH-Resp	See *General PowerPC Handler Response*.
GPP	general-purpose processor
GPQ	PowerPC queue. The queue that contains frames re-enqueued for delivery to the GPH for processing.
GPR	general-purpose register
GTH	See *General Table Handler*.
GUI	graphical user interface
Guided Frame Handler (GFH)	There is one GFH thread available in the EPC. A guided frame can be processed only by the GFH thread, but it can be configured to enable it to process data frames like a GDH thread. The GFH executes guided frame-related picocode, runs device management-related picocode, and exchanges control information with a control point function or a remote network processor. When there is no such task to perform and the option is enabled, the GFH can execute frame forwarding-related picocode.
GxH	Generalized reference to any of the defined threads of the EPC
halfword	2 bytes
HC	Hardware Classifier
HDLC	See *high-level data link control*.

Term	Definition
high-level data link control (HDLC)	In data communication, the use of a specified series of bits to control data links in accordance with the International Standards for HDLC: ISO 3309 Frame Structure and ISO 4335 Elements of Procedures.
I-	Ingress
ICMP	Internet Control Message Protocol
I-DS	Ingress Data Store
Ingress EDS	Ingress Enqueuer / Dequeuer / Scheduler
Ingress GDQ	Ingress General Data Queue
IMS	Interface Manager Services
IPC	interprocess communication
I-PMM	Ingress-Physical MAC Multiplexer
IPPS	Internet Protocol Version 4 Protocol Services
IPv4	Internet Protocol Version 4
I-SDM	Ingress Switch Data Mover
K	2^{10}, or 1024 in decimal notation
KB	kilobyte
Kb	kilobit
LCBA	leaf control block address
LDP	Label Distribution Protocol
leaf	A control block that contains the corresponding key as a reference pattern and other user data such as target blade number, QoS, and so on.
LH	latched high (a characteristic of a register or a bit in a register (facility)). When an operational condition sets the facility to a value of 1, the changes to the operational condition do not affect the state of the facility until the facility is read.
LID	lookup identifier
LL	latched low (a characteristic of a register or a bit in a register (facility)). When an operational condition sets the facility to a value of 0, the changes to the operational condition do not affect the state of the facility until the facility is read.
LLS	low-latency sustainable bandwidth
LPM	longest prefix match
LSb	least significant bit

Term	Definition
LSB	least significant byte
LSP	label-switched path
LU_Def	look-up definition
M	2^{20}, or 1 048 576 in decimal notation
MAC	medium access control
Management Information Base (MIB)	In OSI, the conceptual repository of management information within an open system.
maximum burst size (MBS)	In the Network Processor Egress Scheduler, the duration a flow can exceed its guaranteed minimum bandwidth before it is constrained to its guaranteed minimum bandwidth.
maximum transmission unit (MTU)	In LANs, the largest possible unit of data that can be sent on a given physical medium in a single frame. For example, the MTU for Ethernet is 1500 bytes.
MBS	See *maximum burst size.*
MCC	multicast count
MCCA	multicast count address
MH	MID handler
MIB	See *Management Information Base.*
MID	Multicast ID
MM	MID Manager
MMS	MID Manager Services
MPLS	Multiprotocol Label Switching
Mpps	million packets per second
MSb	most significant bit
MSB	most significant byte
MSC	Message Sequence Charts
MTU	See *maximum transmission unit.*
My_TB	My Target Blade
NBT	next bit to test
NFA	next frame control block (FCB) address

Term	Definition
NLA	next leaf address
NLS	normal latency sustainable bandwidth
NP	Network Processor
NPA	next PCSB address pointer
NPASM	IBM Network Processor Assembler
NPDD	Network Processor Device Driver
NPDDIS	Network Processor Device Driver Initialization Services
NPMS	Network Processor Manager Services
NPScope	IBM Network Processor Debugger
NPSIM	IBM Network Processor Simulator
NPTest	IBM Network Processor Test Case Generator
ns	nanosecond
NTA	next twin-buffer address
OQG	output queue grant
PAP	Password Authentication Protocol
PBS	peak bandwidth service
PC	program counter
PCB	Port Control Block
PCS	Physical Coding Sublayer
PCT	port configuration table
PHY	See *physical layer*. May also refer to a physical layer device.
physical layer	In the Open Systems Interconnection reference model, the layer that provides the mechanical, electrical, functional, and procedural means to establish, maintain, and release physical connections over the transmission medium. (T)
PLB	Processor Local Bus
PLL	phased lock loop
PMA	physical medium attachment
PMM	Physical MAC Multiplexer
PolCB	Policing Control Block

Term	Definition
POS	packet over SONET (also IP over SONET)
POST	power-on self-test
postcondition	An action or series of actions that the user program or the NPDD must perform after the function has been called and completed. For example, when the function that defines a table in the NPDD has been completed, the NPDD must dispatch a guided frame from the PowerPC core to instruct one or more EPCs to define the table.
PPC	PowerPC
PPP	Point-to-Point Protocol
PPrev	Previous Discard Probability
precondition	A requirement that must be met before the user program calls the API function. For example, a precondition exists if the user program must call one function and allow it to be completed before a second function is called. One function that has a precondition is the function that deregisters the user program. The user program must call the register function to obtain a *user_handle* before calling the deregistering function.
ps	picosecond
PSCB	pattern search control block
PTL	Physical Transport Layer
PTS	Physical Transport Services
quadword	4 words
quality of service (QoS)	For a network connection, a set of communication characteristics such as end-to-end delay, jitter, and packet loss ratio.
QCB	queue control block
QoS	See *quality of service.*
Rbuf	raw buffer
RCB	Reassembly Control Block
RCLR	read current leaf from rope
RED	random early detection
RMON	Remote Network Monitoring
rope	leaves in a tree linked together in a circular list
RPC	remote procedure call

Term	Definition
RTP	Real-Time Transport Protocol
RUM	Access type “reset under mask”
R/W	Access type “Read/Write”
RWR	Access type “Read with Reset”
SA	source address
SAP	service access point
SC	self-clearing (a characteristic of a register or a bit in a register (facility)). When written to a value of 1, will automatically reset to a value of 0 when the indicated operation completes.
SCB	Scheduler control block
SCI	Switch Cell Interface
SDC	shared DASL controller
SDM	Switch Data Mover
SMT	software-managed tree
SMII	Serial Media-Independent Interface
SOF	start-of-frame
SONET	Synchronous Optical Network
SPM	Serial/Parallel Manager
SRAM	static random-access memory
SS	System Services
SUM	Access type “set under mask”
SWI	Switch Interface
Target Blade Grant (TBG)	An internal facility used by the ingress scheduler to determine which target blades are accepting data transfer. Derived from the output queue grant (OQG) information the network processor receives.
TB	target blade
TBG	See *Target Blade Grant*.
TBI	Ten-Bit Interface
TBR	target blade running
TB_SOF	target blade start-of-frame

Term	Definition
TCP	Transmission Control Protocol
TDMU	target DMU
thread	A stream of picocode instructions that utilizes a private set of registers and shared computational resources within a DPPU. In the network processor, a DPPU provides both shared and private resources for four threads. Two threads are bound to a single picoprocessor, allowing for concurrent execution of two threads within a DPPU. The coprocessors are designed to support all four threads. In general, the computational resources (ALU, hardware-assist state machines, and so on) are shared among the threads. The private resources provided by each picoprocessor or coprocessor include the register set that makes up its architecture (GPRs, program counters, link stacks, DataPool, and so on).
TLIR	tree leaf insert rope
TLV	type length vectors
TMS	Table Management Services
TP	target port
TSDQFL	Tree Search Dequeue Free List
TS	Transport Services
TSE	Tree Search Engine
TSENQFL	Tree Search Enqueue Free List
TSFL_ID	tree search free list identifier
TSR	tree search result
TTL	time to live
UC	Unicast
UDP	User Datagram Protocol
WFQ	weighted fair queueing
word	4 bytes
ZBT	zero bus turnaround

Revision Log

Rev	Description of Modification
11/11/99	Initial release of databook for IBM32NPR161EPXCAC133 (revision 00), follow-up document to datasheet for IBMNPR100EXXCAB133 and IBM32NPR161EPXCAC133 (revision 01, 11/08/99)
02/28/00	Release IBM32NPR161EPXCAC133 (revision 01), including revised sections 1 and 5.
03/17/00	Release IBM32NPR161EPXCAC133 (revision 02), including revised sections 2, 8, 10, 12, and 13
03/31/00	Release IBM32NPR161EPXCAC133 (version 03), including revisions to all sections.
05/26/00	Release IBM32NPR161EPXCAC133 (revision 04), including revised sections 1, 2, 3, 4, 5, 6, 7, 8, 10, 11, 12, 13, 14. In section 2: - Redefinition of some signal pins - Full description of Thermal Monitor In section 6: - Descriptions of the Discard Port Queue (DPQ) and the Discard Queue Stack (GDQ) - An updated table about valid combinations of scheduler parameters - A table about configuring a flow QCB In section 8: - Updated CS address map - Updated various registers and operand descriptions In section 14: - A capacitance table was added. - Thermal information was updated.
07/13/00	Updated Revision Log for Completeness Global changes: IBM Network Processor changed to either IBM Power Network Processor or NP4GS3 Cross-References updated Wording for readability updated Typographical errors corrected Section 1 - Overview: p. 1 Features updated p. 2 Ordering info table streamlined Section 2 - Physical Description p. 9 Figure 4 updated p. 11 Table 1 updated (one more RISCWatch/JTAG added; added note) p. 21 Table 12 updated p. 22 Table 14 updated pp. 32-3 Sections 2.1.2, 2.1.3.1, 2.1.4.2 added p. 56 Table 24 updated Section 3 - PMM p. 63 Table 26 updated p. 68 Sections 3.2.1 and 3.2.2.1 added p. 68-71 Tables 29 and 30 updated Section 4 - IEDS p. 80 Description of round-robin scheduling rewritten Section 5 - Switch p. 85 Text updated (re: DASL link throughput) pp. 95-6 Added more specific sequence info under OQG Reporting

Revision Log

Rev	Description of Modification
07/13/00 (cont.)	Section 6 - EEDS overall GPQ changed to PPG p. 1 Items added to overview p. 100 Definitions of DPQ and GDQ expanded p. 109 Table 42 updated p. 113 Table 43 updated Section 7 - EPC p. 122 Table 46 updated p. 125 Text updated (# of available commands) p. 133 Table 53 updated p. 138 TWINLEASE command changed to LEASETWIN p. 142 Figure 40 updated p. 143 Table 71 updated p. 145 Figure 41 updated p. 146 Table 72 updated p. 148-50 Tables 73, 74, 75, and 78 updated p. 153 Note added to Table 84 p. 159 Table 98 expanded p. 160-1 Tables 99, 100, 101, and 102 updated p. 172 DLL Termination text expanded p. 177 External counter item expanded Section 8 - Tree p. 188 Table 123 updated p. 188-9 Section 8.1.2 added p. 190 Descriptive text (re: Figure 48) added p. 192-229 Tables 125, 135, 141, 143, 147-162, 164-165, 172, 174-176, 185, 187, and 189 updated Section 10 - EPPC p. 246 DCR base addresses updated p. 250 PLB addresses updated p. 255 Sec 10.7.3 register updated p. 256 Sec. 10.7.4 register updated p. 259 Sec. 10.7.7 register updated p. 260 Sec. 10.7.8 register updated Section 12 - Debug p. 313-4 Sec. 12.4 (Port Mirroring) updated; previous sec 12.4 (Probe) deleted Section 13 -Config p. 316 Sch_Ena definition updated p. 319 D0_Width and DRAM_Size definitions updated p. 326 Bit 18 now reserved p. 336 BL_Override definition updated p. 338 Sec. 13.13.6 changed from Enable to Disable p. 342 Text updated; Most Significant Bit is now 0 p. 343 Text updated p. 360 Intro text added p. 365 Sec. 13.20 GQ_Max Register changed to FCB_FQ_Max Register Section 14 - Electrical and Thermal Specs p. 381 Table 208 added (replaces old Capacitance table) p. 402 Table 210 updated Section 15 - Glossary p. 408 ECC added to list

Revision Log

Rev	Description of Modification
07/28/00	Release IBM32NPR161EPXCAC133 (revision 05). All sections revised for: typographical accuracy, syntactical clarity, standardized appearance of field and signal names, updated or additional cross-references for navigation. Substantive changes include: Preface - p. xix Corrected URL for PPC405GP Section 2 - Physical Description p. 35-54 Tables 22 & 23 updated. Signal Pin JTAG_TDO moved from N22 to AA23. N22 is now Unused. Section 6 - EEDS p. 105 Table 40 updated. p. 111 QD description updated. Section 7 - EPC p. 125 7.2.3 text - Configuration Quadword Array item added p. 154-7 7.2.6.2 - CheckSum Coprocessor Commands clarified p. 169 Table 112 - GT field comparison deleted Section 8 - Tree Search Engine p. 191 8.1.2 text - expanded DT entry item p. 195 8.1.5 text updated p. 197-8 8.2.1 text updated p. 206-8 Table 142 updated p. 226 Tables 184 and 186 updated Section 11 - Reset p. 299 Intro text added p. 300-1 11.2 Step 1 text and Table 202 updated p. 306 11.10 Step 9 text updated Section 14 - Electrical & Thermal p. 385-405Table 212 updated. Signal Pin JTAG_TDO moved from N22 to AA23. N22 is now Unused.
09/25/00	Release IBM32NPR161EPXCAC133 (revision 06). All sections revised for: typographical accuracy and syntactical clarity. Page numbering of front material changed to consecutive arabic numerals. Substantive changes include: Section 2 - Physical Description p. 32-70 Changed signal types on Tables 2, 3, 7-9, 11, 13, 17, 19, 21, 23, 25, 27, 29. Added Tables 6, 12, 18, 20, 22, 24, 26, 28, 30, 31 Added Figures 5- 8, 11-16, 20 p. 44-5 Tables 14 and 16 - Altered field names p. 50-1 Table 19 - Redefined $\overline{\text{CPDetect}}$ field p. 59-60 Table 25 - Added note Section 4 - IEDS p. 117 4.3.3.2 - Clarified definition of T field Section 6 - EEDS p. 141-3 6.3.3 - Added RES Bus section p. 143 6.3.4.2 - Expanded third bullet text p. 148 6.4.2.2 - Clarified TH explanation all Changed PPQ to GPQ, GDQ to E-GDQ Section 7 - EPC p. 171-6 Added Tables 64, 66, 68, 70, 75, 77 p. 191-7 Added Tables 102, 114 p. 216-7 Table 137 - Clarified PolCB field definitions Section 8 - Tree Search Engine p. 246 Table 159 - Redefined LeafTH field 8.2.5.2 - Clarified text Table 160 - Redefined Threshold field p. 254-5 Tables 175, 177 - Clarified LUDefIndex field

Revision Log

Rev	Description of Modification
09/25/00 (cont.)	Section 10 - EPPC p. 325 10.8.22 - Corrected CAB address Section 11 - Reset p. 338 11.2 - Added text p. 339 11.3 - Added text Section 13 - Configuration p. 372 13.11.1 - Updated text p. 397 13.14.5 - Redefined fields Section 14 - Electrical & Thermal p. 423 Updated Table 228 p. 444-9 Added or updated Tables 231-47
March 2001	IBM32NPR161EPXCAD133 (rel. 1.1) & IBM32NPR161EPXCAE133 (rel 2.0) (revision 07). Changed “databook” to “datasheet” throughout. Updated figure and table caption formats. Substantive changes include: Section 1 - Overview Section 2 - PHY updated all timing diagrams and related tables added timing information for NP4GS3A (R1.1) and NP4GS3B (R2.0) to all timing tables Table 32 (Mechanical Specifications) - removed footer and header shading added definition to D4 Data Strobes signal in D4_0 / D4_1 Memory Pins table added definitions to DS0 and DS1 Data Strobes signals in DS0 and DS1 Pins table reworded PCI definitions in Type column of PCI Interface Pins table changed PLL values in Clock Generation and Distribution figure Section 3 - PMM Figure 29: Changed TxAddr to RxAddr and added footnote 1 Figure 32: Added TxAddr row and added footnote 1 Section 4 - Ingress-EDS Figure 49 - added set of SOF rings Section 5 - Switch Interface Table 50 - revised definitions for Qualifier, ST, QT(1:0), and EndPtr

Revision Log

Rev	Description of Modification
March 2001 (continued)	Section 7 - EPC 7.2.2/3 - added section on CLP commands and opcodes 7.8 - added section on Semaphore Coprocessor Section 8 - Tree Search Engine 8.2.3.4 - added paragraph on caches in LUDefTable Table 173 - updated LUDefTable Entry Definitions 8.2.6 - updated bit definitions for LUDEFCopy_GDH definition 8.2.7 - added new introductory paragraph 8.2.7.9 - 8.2.7.12 - added DISTPOS_GDH, RDPSCB_GDH, WRPSCB_GDH, and SetPatBit_GDH sections Section 11 - Reset and Initialization Tables 239 and 242 - added information about external physical devices to Setup 2 and Configure checklists Section 12 - Debug 12.5 - added further explanation to step 1 of Set Up Port Mirroring Section 13 - Configuration 13.1.1 - redefined fields 13.1.2 - added new base offset and redefined fields 13.6 - updated text 13.11.1 - updated text 13.14.5 - redefined fields, added base offsets 0 and 1 13.30.2 - added section on DASL interface Section 14 - Electrical and Thermal Specifications Added new Input Capacitance table information Updated thermal and voltage table information 14.3.1 - Added DASL interface specification tables Section 15 - Glossary Added definition for even parity Added definition for picosecond Added definition for rope Added definition for TBI Structural and Stylistic Edits Preface Rewrote “Who Should Read This Manual” section Added three URLs Updated conventions Section 1 - General Information Entire chapter rewritten & reorganized for clarity Section 2 - Physical Description 2.1 - Rewrote introduction and created navigation table Rearranged tables in section Added subsections with introductory paragraphs to match navigation table Section 3 - Physical MAC Multiplexer Changed section title from “PMM Overview” Minor edits and rewordings throughout 3.4.1 - heavy edit 3.5.1 - heavy edit

Revision Log

Rev	Description of Modification
March 2001 (continued)	Section 4 - Ingress EDS Rewrote most paragraphs to change text to active voice Section 5 - Switch Interface Minor edits throughout Switched sections 5.4.1 “Output Queue Grant Reporting” and 5.4.2 “Switch Fabric to Network Processor Egress Idle Cell.” Moved tables in those sections. Section 6 - Egress EDS Switched positions of Table 6-3 and Figure 6-7; adjusted text accordingly Minor edits throughout Section 7 - EPC Moderate edits throughout Moved tree search engine summary from overview into DPPU section Moved DPPU coprocessors and coprocessor opcodes out of “DPPU” and set them up as their own level 2 sections. Combined each “Coprocessor Commands” list with the corresponding “Coprocessor Summary” table Section 9 - Serial / Parallel Manager Moderate edits throughout Section 13 - Configuration Renamed section (from “NP4GS3 Configuration”) Sections 8, 10, 11, 12, 14, and 15 Moderate edits
May 2001	Section 1 - Overview minor revisions to sections 1.3 and 1.5 Section 2 - PHY Timing information for theD6 DDR has been split out from the other DDRs. Minor changes to timing table information throughout Section 3 - PMM 3.2.1 POS Timing diagrams updated Tables 3-6 and 3-7 updated Section 4 - IEDS 4.2 Added description of TB_Mode register control of multiple in-flight I-EDS frames. Section 5 - Switch Interface Table 5.1 requirements for frame packing have been corrected. Section 7 - EPC Table 7-47 Ingress Target Queue FCBPage Parameters, parameter definition note for PIB added. Section 8 - TSE Added section 8.1.3, Logical Memory Views of D6. Section 10 - PowerPC 10.4 - PCI/PLB Macro. Added a second overview paragraph explaining configuration options. Section 13 - Configuration 13.21 - Frame Control Block FQ Size Register definition expanded 13.31.1 - DASL Configuration register bits 31:29 redefined Section 14 - Electrical and Thermal Updated tables 14-3 and 14-4.
