MC80C0304/0308/0316

CMOS SINGLE-CHIP 8-BIT MICROCONTROLLER WITH 10-BIT A/D CONVERTER AND UART

1. OVERVIEW

1.1 Description

The MC80F0304/0308/0316 is advanced CMOS 8-bit microcontroller with 4K/8K/16K bytes of FLASH. This is a powerful microcontroller which provides a highly flexible and cost effective solution to many embedded control applications. This provides the following features : 4K/8K/16K bytes of FLASH, 256 bytes of RAM, 8/16-bit timer/counter, watchdog timer, 10-bit A/D converter, 8-bit Serial Input/Output, UART, buzzer driving port, 10-bit PWM output and on-chip oscillator and clock circuitry. It also has ONP, noise filter, PFD for improving noise immunity. In addition, the MC80F0304/0308/0316 supports power saving modes to reduce power consumption.

This document explains the base MC80F0316, the other's eliminated functions are same as below table.

Device Name		FLASH Size	RAM	ADC	I/O PORT	Package
FLASH	MASK ROM					
MC80F0304B/08B/16B	MC80C0304B/08B/16B	4K/8K/16K	512B	16 channel	30 port	32 PDIP
MC80F0304G/08G/16G	MC80C0304G/08G/16G			16 channel	26 port	28 SKDIP

1.2 Features

- **4K/8K/16K Bytes On-chip FLASH**
 - 488Hz ~ 250kHz@4MHz
- **FLASH Memory**
 - Endurance : 100 cycles
 - Data retention time : 10 years
- **512 Bytes On-chip Data RAM (Included stack memory)**
- **Minimum Instruction Execution Time:**
 - 333ns at 12MHz (NOP instruction)
- **Programmable I/O pins (LED direct driving can be a source and sink)**
 - MC80F0316B : 30(29)
 - MC80C0316G : 26(25)
- **One 8-bit Basic Interval Timer**
- **Four 8-bit Timer/counters (or two 16-bit Timer/counter)**
- **One Watchdog timer**
- **Two 10-bit High Speed PWM Outputs**
- **10-bit A/D converter : 10 channels**
- **Two 8-bit Serial Communication Interface**
 - One Serial I/O and one UART
- **One Buzzer Driving port**
- **Four External Interrupt input ports**
- **On-chip POR (Power on Reset)**
- **Thirteen Interrupt sources**
 - External input : 4
 - Timer : 6
 - A/D Conversion : 1
 - Serial Interface : 1
 - UART : 1
- **Built in Noise Immunity Circuit**
 - Noise filter
 - PFD (Power fail detector)
 - ONP (Oscillation Noise Protector)
- **Power Down Mode**
 - Stop mode
 - Wake-up timer mode
 - Internal RC-Oscillated watchdog timer mode
- **Operating Voltage & Frequency**
 - 2.7V ~ 5.5V (at 0.4 ~ 8MHz) : FLASH
 - 2.0V ~ 5.5V (at 0.4 ~ 4.2MHz) : MASK
 - 4.5V ~ 5.5V (at 0.4 ~ 12MHz) : FLASH, MASK
- **Operating Temperature : -40°C ~ 85°C**
- **Oscillator Type**

- Crystal
- Ceramic resonator
- External RC Oscillator (C can be omitted)
- Internal Oscillator (4MHz/2MHz)

1.3 Development Tools

The MC80F0304/0308/0316 is supported by a full-featured macro assembler, an in-circuit emulator CHOICE-Dr.TM and OTP programmers. There are two different type of programmers such as single type and gang type. For mode detail, Macro assembler operates under the MS-Windows 95 and upversioned Windows OS.

Please contact sales part of MagnaChip semiconductor.

Software	- MS-Windows based assembler - MS-Windows based Debugger - HMS800 C compiler
Hardware (Emulator)	- CHOICE-Dr. - CHOICE-Dr. EVA80C0x B/D
FLASH Writer	- CHOICE - SIGMA I/II(Single writer) - PGM Plus I/II/III(Single writer) - Standalone GANG4 I/II(Gang writer)

Choice-Dr. (Emulator)

PGMplus III (Single Writer)

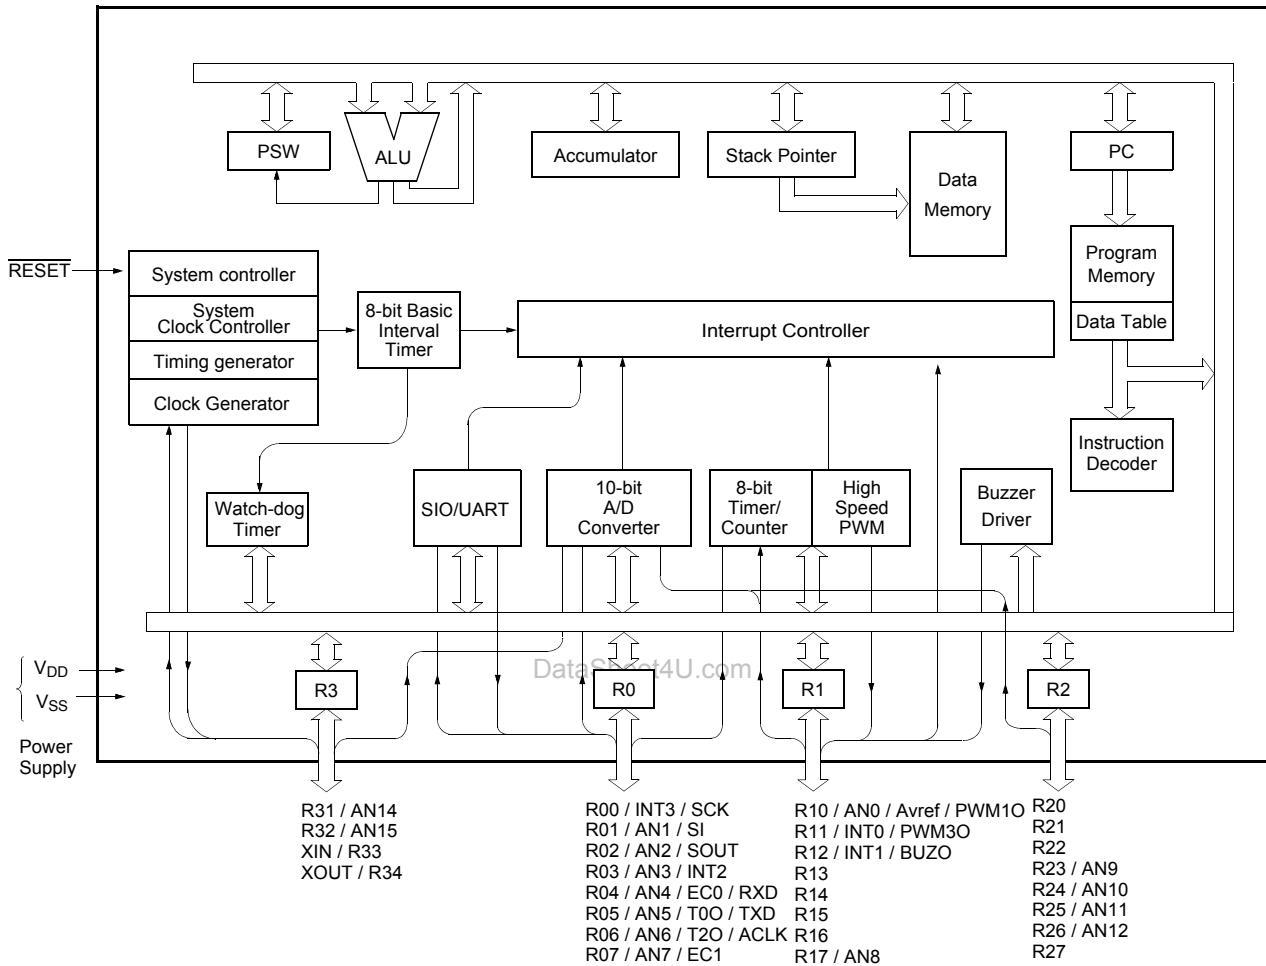

Standalone Gang4 II (Gang Writer)

5. PIN FUNCTION

V_{DD}: Supply voltage.

V_{SS}: Circuit ground.

RESET: Reset the MCU.

X_{IN}: Input to the inverting oscillator amplifier and input to the internal main clock operating circuit.

X_{OUT}: Output from the inverting oscillator amplifier.

R00~R07: R0 is an 8-bit, CMOS, bidirectional I/O port. R0 pins can be used as outputs or inputs according to “1” or “0” written the their Port Direction Register(R0IO).

Port pin	Alternate function
R00	INT3 (External Interrupt Input Port3) SCK (SPI CLK)
R01	AN1 (Analog Input Port 1) SI (SPI Serial Data Input)
R02	AN2 (Analog Input Port 2) SOUT (SPI Serial Data Output)
R03	AN3 (Analog Input Port 3) INT2 (External Interrupt Input Port2)
R04	AN4 (Analog Input Port 4) EC0 (Event Counter Input Source 0) RXD (UART Data Input)
R05	AN5 (Analog Input Port 5) T00 (Timer0 Clock Output) TXD (UART Data Output)
R06	AN6 (Analog Input Port 6) T20 (Timer2 Clock Output) ACLK (UART Clock Input)
R07	AN7 (Analog Input Port 7) EC1 (Event Counter Input Source 1)

Table 5-1 R0 Port

In addition, R0 serves the functions of the various special features in Table 5-1 .

R10~R14: R1 is a 5-bit, CMOS, bidirectional I/O port. R1 pins can be used as outputs or inputs according to “1” or “0” written the their Port Direction Register (R1IO).

R1 serves the functions of the various following special

features in Table 5-2

Port pin	Alternate function
R10	AN0 (Analog Input Port 0) AVref (External Analog Reference Pin) PWM1O (PWM1 Output)
R11	INT0 (External Interrupt Input Port 0) PWM3O (PWM3 Output)
R12	INT1 (External Interrupt Input Port 1) BUZ (Buzzer Driving Output Port)
R13	-
R14	-
R15	-
R16	-
R17	AN8(Analog Input Port 8)

Table 5-2 R1 Port

R20~R21 : R2 is an 8-bit, CMOS, bidirectional I/O port. R2 pins can be used as outputs or inputs according to “1” or “0” written the their Port Direction Register(R2IO)

In addition, R2 serves the functions of the various special features in Table 5-3 .

Port pin	Alternate function
R20	-
R21	-
R22	-
R23	AN9 (Analog Input Port 9)
R24	AN10 (Analog Input Port 10)
R25	AN11 (Analog Input Port 11)
R26	AN12 (Analog Input Port 12)
R27	-

Table 5-3 R2 Port

R31~R34: R3 is a 4-bit, CMOS, bidirectional I/O port. R3 pins can be used as outputs or inputs according to “1” or “0” written the their Port Direction Register (R3IO).

R3 serves the functions of the serial interface following special features in Table 5-4 .

Port pin	Alternate function
R30	AN13 (Analog Input Port 13)
R31	AN14 (Analog Input Port 14)
R32	AN15 (Analog Input Port 15)
R33	X _{IN} (Oscillation Input)
R34	X _{OUT} (Oscillation Output)
R35	RESETB (Reset input port)

7. ELECTRICAL CHARACTERISTICS

7.1 Absolute Maximum Ratings

Supply voltage-0.3 to +6.5 V

Storage Temperature-65 to +150 °C

Voltage on any pin with respect to Ground (V_{SS})
-0.3 to $V_{DD}+0.3V$

Maximum current out of V_{SS} pin 200 mA

Maximum current into V_{DD} pin 100 mA

Maximum current sunk by (I_{OL} per I/O Pin) 20 mA

Maximum output current sourced by (I_{OH} per I/O Pin)
10 mA

Maximum current (ΣI_{OL}) 160 mA

Maximum current (ΣI_{OH}) 80 mA

Note: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

7.2 Recommended Operating Conditions

Parameter	Symbol	Condition	Specifications		Unit
			Min.	Max.	
Supply Voltage	V_{DD}	$f_{XIN}=0.4\sim 12MHz$ $f_{XIN}=0.4\sim 8MHz$	4.5 2.5	5.5 5.5	V
Operating Frequency	f_{XIN}	$V_{DD}=4.5\sim 5.5V$ $V_{DD}=2.7\sim 5.5V(MC80F03XXX)$ $V_{DD}=2.0\sim 5.5V(MC80C03XXX)$	0.4 0.4 0.4	12 8 4.2	MHz
Operating Temperature	T_{OPR}	$V_{DD}=2.7\sim 5.5V(MC80F03XXX)$ $V_{DD}=2.0\sim 5.5V(MC80C03XXX)$	-40	85	°C

7.3 A/D Converter Characteristics

($T_a=-40\sim 85^\circ C$, $V_{SS}=0V$, $V_{DD}=2.7\sim 5.5V$ @ $f_{XIN}=8MHz$)

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
Resolution		-	-	10	-	BIT
Overall Accuracy	-	-	-	-	± 3	LSB
Integral Linearity Error	ILE	$V_{DD} = AV_{REF} = 5V$ CPU Clock = 10MHz $V_{SS} = 0V$	-	-	± 3	LSB
Differential Linearity Error	DLE		-	-	± 3	LSB
Offset Error of Top	EOT		-	± 1	± 3	LSB
Offset Error of Bottom	EOB		-	± 0.5	± 3	LSB
Conversion Time	T_{CONV}		-	13	-	-
Analog Input Voltage	V_{AIN}	-	V_{SS}	-	V_{DD} (AV_{REF})	V
Analog Reference Voltage	AV_{REF}	-	TBD	-	V_{DD}	V
Analog Input Current	I_{AIN}	$V_{DD} = AV_{REF} = 5V$	-	-	10	μA

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
Analog Block Current	I _{AVDD}	V _{DD} = AV _{REF} = 5V	-	1	3	mA
		V _{DD} = AV _{REF} = 3V	-	0.5	1.5	
		V _{DD} = AV _{REF} = 5V power down mode	-	100	500	nA

7.4 DC Electrical Characteristics

(T_A=-40~85° C, V_{DD}=5.0V, V_{SS}=0V),

Parameter	Symbol	Pin	Condition	Specifications			Unit
				Min.	Typ.	Max.	
Input High Voltage	V _{IH1}	X _{IN} , RESET ¹		0.8 V _{DD}	-	V _{DD}	V
	V _{IH2}	Hysteresis Input ¹		0.8 V _{DD}	-	V _{DD}	
	V _{IH3}	Normal Input		0.7 V _{DD}	-	V _{DD}	
Input Low Voltage	V _{IL1}	X _{IN} , RESET ¹		0	-	0.2 V _{DD}	V
	V _{IL2}	Hysteresis Input ¹		0	-	0.2 V _{DD}	
	V _{IL3}	Normal Input		0	-	0.3 V _{DD}	
Output High Voltage	V _{OH}	All Output Port	V _{DD} =5V, I _{OH} =-5mA	V _{DD} -1	-	-	V
Output Low Voltage	V _{OL}	All Output Port	V _{DD} =5V, I _{OL} =10mA	-	-	1	V
Input Pull-up Current	I _P	Normal Input	V _{DD} =5V	-70	-	-130	μA
Input High Leakage Current	I _{IH1}	All Pins (except X _{IN})	V _{DD} =5V	-	-	5	μA
	I _{IH2}	X _{IN}	V _{DD} =5V	-	-	15	μA
Input Low Leakage Current	I _{IL1}	All Pins (except X _{IN})	V _{DD} =5V	-5	-	-	μA
	I _{IL2}	X _{IN}	V _{DD} =5V	-15	-	-	μA
Hysteresis	V _T	Hysteresis Input ¹	V _{DD} =5V	0.5	-	-	V
PFD Voltage	V _{PFD}	V _{DD}		2.0	-	3.0	V
Internal RC WDT Period	T _{RCWDT}	X _{OUT}	V _{DD} =5.5V	36	-	90	μS
Operating Current ²	I _{DD}	V _{DD}	V _{DD} =5.5V, f _{XIN} =8MHz	-	4	6.5	mA
			V _{DD} =3.0V, f _{XIN} =4MHz	-	2	3	
Wake-up Timer Mode Current	I _{WKUP}	V _{DD}	V _{DD} =5.5V, f _{XIN} =8MHz	-	1	2	mA
			V _{DD} =3.0V, f _{XIN} =4MHz	-	0.3	1	
RCWDT Mode Current at STOP Mode	I _{RCWDT}	V _{DD}	V _{DD} =5.5V	-	30	70	μA
			V _{DD} =3.0V	-	5	50	
Stop Mode Current	I _{STOP}	V _{DD}	V _{DD} =5.5V, f _{XIN} =8MHz	-	0.5	3	μA
			V _{DD} =3.0V, f _{XIN} =4MHz	-	0.2	1	
Internal Oscillation Frequency	T _{IN_CLK}	X _{OUT}	V _{DD} =5V	3	4	5	MHz

Parameter	Symbol	Pin	Condition	Specifications			Unit
				Min.	Typ.	Max.	
External RC Oscillator Frequency	f_{RC-OSC}	$f_{XOUT} = f_{RC-OSC} \div 4$	$V_{DD}=5.5V$ $R=30k\Omega$, $C=10pF$	0.7	-	1.5	MHz
	f_{R-OSC}	$f_{XOUT} = f_{R-OSC} \div 4$	$V_{DD}=5.5V$ $R=30k\Omega$	2	-	4	MHz

1. Hysteresis Input: INT0 ~ INT3(R11,R12,R03,R00),SIO(R00,R01,R02),UART(R04,R06,EC0,EC1)
2. This parameter is measured in internal PROM operation at the all I/O port defined input mode.

7.5 AC Characteristics

($T_A=-40\sim+85^\circ C$, $V_{DD}=5V\pm 10\%$, $V_{SS}=0V$)

Parameter	Symbol	Pins	Specifications			Unit
			Min.	Typ.	Max.	
Operating Frequency	f_{CP}	X_{IN}	0.4	-	12	MHz
External Clock Pulse Width	t_{CPW}	X_{IN}	35	-	-	nS
External Clock Transition Time	t_{RCP}, t_{FCP}	X_{IN}	-	-	20	nS
Oscillation Stabilizing Time(4Mhz)	t_{ST}	X_{IN}, X_{OUT}	-	-	20	mS
External Input Pulse Width	t_{EPW}	INT0, INT1, INT2, INT3 EC0, EC1	2	-	-	tsys
\overline{RESET} Input Width	t_{RST}	\overline{RESET}	8	-	-	tsys

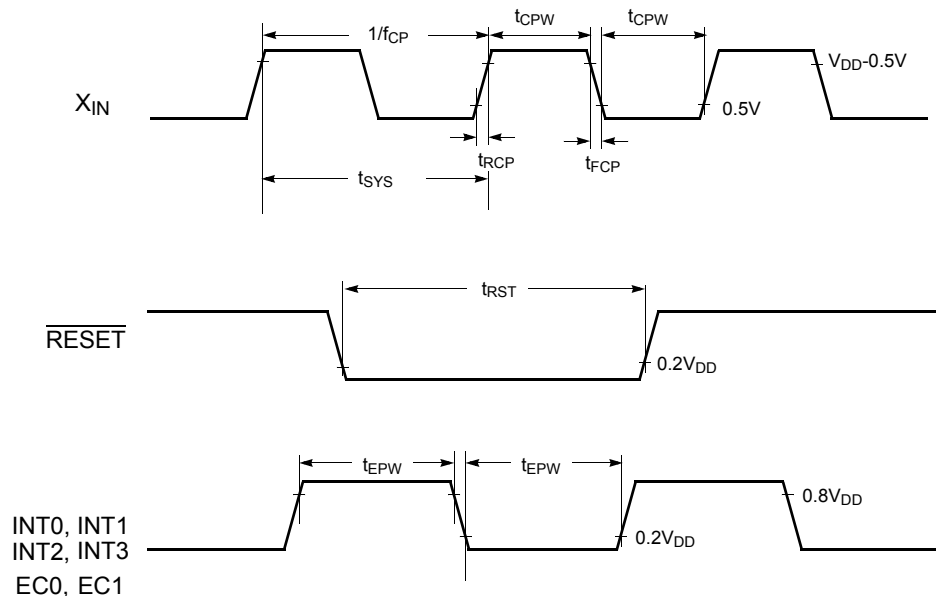

Figure 7-1 Timing Chart

7.6 Typical Characteristics

These graphs and tables provided in this section are for design guidance only and are not tested or guaranteed.

In some graphs or tables the data presented are outside specified operating range (e.g. outside specified V_{DD} range). This is for information only and devices are guaranteed to operate properly only within the specified range.

The data presented in this section is a statistical summary of data collected on units from different lots over a period of time. “Typical” represents the mean of the distribution while “max” or “min” represents $(\text{mean} + 3\sigma)$ and $(\text{mean} -$

$3\sigma)$ respectively where σ is standard deviation

TBD

8. MEMORY ORGANIZATION

The MC80F0304/0308/0316 has separate address spaces for Program memory and Data Memory. 4K bytes program memory can only be read, not written to.

8.1 Registers

This device has six registers that are the Program Counter (PC), a Accumulator (A), two index registers (X, Y), the Stack Pointer (SP), and the Program Status Word (PSW). The Program Counter consists of 16-bit register.

Figure 8-1 Configuration of Registers

Accumulator: The Accumulator is the 8-bit general purpose register, used for data operation such as transfer, temporary saving, and conditional judgement, etc.

The Accumulator can be used as a 16-bit register with Y Register as shown below.

Figure 8-2 Configuration of YA 16-bit Register

X, Y Registers: In the addressing mode which uses these index registers, the register contents are added to the specified address, which becomes the actual address. These modes are extremely effective for referencing subroutine tables and memory tables. The index registers also have increment, decrement, comparison and data transfer functions, and they can be used as simple accumulators.

Stack Pointer: The Stack Pointer is an 8-bit register used for occurrence interrupts and calling out subroutines. Stack Pointer identifies the location in the stack to be accessed (save or restore).

Generally, SP is automatically updated when a subroutine

Data memory can be read and written to up to 256 bytes including the stack area.

call is executed or an interrupt is accepted. However, if it is used in excess of the stack area permitted by the data memory allocating configuration, the user-processed data may be lost.

The stack can be located at any position within 1C0H to 1FFH of the internal data memory. The SP is not initialized by hardware, requiring to write the initial value (the location with which the use of the stack starts) by using the initialization routine. Normally, the initial value of "FFH" is used.

Note: The Stack Pointer must be initialized by software because its value is undefined after Reset.

Example: To initialize the SP

```
LDX    #0FFH
TXSP                      ; SP ← FFH
```

Program Counter: The Program Counter is a 16-bit wide which consists of two 8-bit registers, PCH and PCL. This counter indicates the address of the next instruction to be executed. In reset state, the program counter has reset routine address (PCH:0FFH, PCL:0FEH).

Program Status Word: The Program Status Word (PSW) contains several bits that reflect the current state of the CPU. The PSW is described in Figure 8-3 . It contains the Negative flag, the Overflow flag, the Break flag the Half Carry (for BCD operation), the Interrupt enable flag, the Zero flag, and the Carry flag.

[Carry flag C]

This flag stores any carry or borrow from the ALU of CPU after an arithmetic operation and is also changed by the Shift Instruction or Rotate Instruction.

[Zero flag Z]

This flag is set when the result of an arithmetic operation or data transfer is "0" and is cleared by any other result.

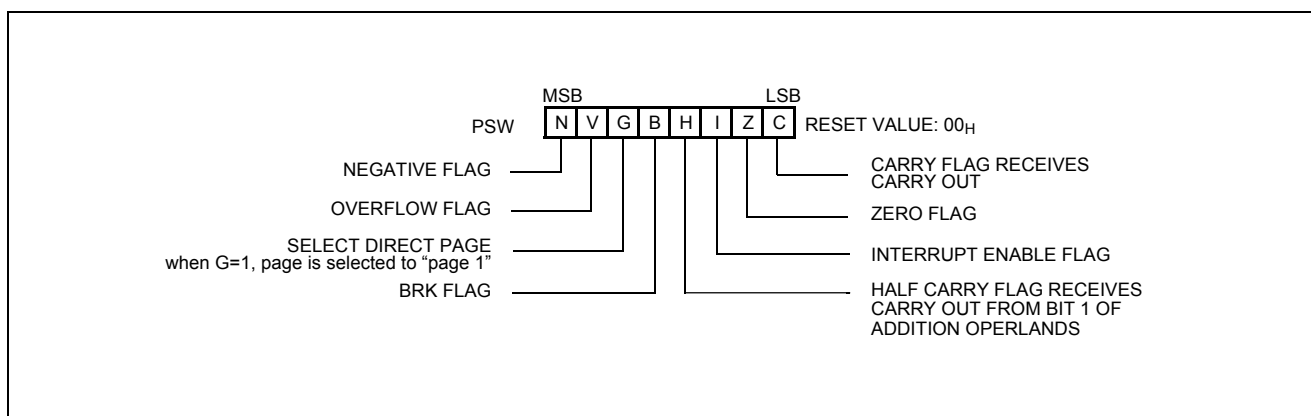

Figure 8-3 PSW (Program Status Word) Register

[Interrupt disable flag I]

This flag enables/disables all interrupts except interrupt caused by Reset or software BRK instruction. All interrupts are disabled when cleared to "0". This flag immediately becomes "0" when an interrupt is served. It is set by the EI instruction and cleared by the DI instruction.

[Half carry flag H]

After operation, this is set when there is a carry from bit 3 of ALU or there is no borrow from bit 4 of ALU. This bit can not be set or cleared except CLR_V instruction with Overflow flag (V).

[Break flag B]

This flag is set by software BRK instruction to distinguish BRK from T_{CALL} instruction with the same vector address.

[Direct page flag G]

This flag assigns RAM page for direct addressing mode. In the direct addressing mode, addressing area is from zero page 00_H to 0FF_H when this flag is "0". If it is set to "1", addressing area is assigned 100_H to 1FF_H. It is set by SET_G instruction and cleared by CLR_G.

[Overflow flag V]

This flag is set to "1" when an overflow occurs as the result of an arithmetic operation involving signs. An overflow occurs when the result of an addition or subtraction exceeds +127(7F_H) or -128(80_H). The CLR_V instruction clears the overflow flag. There is no set instruction. When the BIT instruction is executed, bit 6 of memory is copied to this flag.

[Negative flag N]

This flag is set to match the sign bit (bit 7) status of the result of a data or arithmetic operation. When the BIT instruction is executed, bit 7 of memory is copied to this flag.

Figure 8-4 Stack Operation

8.2 Program Memory

A 16-bit program counter is capable of addressing up to 64K bytes, but this device has 4K/8K/16K bytes program memory space only physically implemented. Accessing a location above FFFF_H will cause a wrap-around to 0000_H.

Figure 8-5, shows a map of Program Memory. After reset, the CPU begins execution from reset vector which is stored in address FFFE_H and FFFF_H as shown in Figure 8-6.

As shown in Figure 8-5, each area is assigned a fixed location in Program Memory. Program Memory area contains the user program

Figure 8-5 Program Memory Map

Page Call (PCALL) area contains subroutine program to reduce program byte length by using 2 bytes PCALL instead of 3 bytes CALL instruction. If it is frequently called, it is more useful to save program byte length.

Table Call (TCALL) causes the CPU to jump to each TCALL address, where it commences the execution of the service routine. The Table Call service area spaces 2-byte for every TCALL: 0FFC0_H for TCALL15, 0FFC2_H for TCALL14, etc., as shown in Figure 8-7.

Example: Usage of TCALL

```

LDA    #5
      TCALL 0FH      ; 1BYTE INSTRUCTION
      :             ; INSTEAD OF 3 BYTES
      :             ; NORMAL CALL
;
; TABLE CALL ROUTINE
;
FUNC_A: LDA    LRG0
      RET
;
FUNC_B: LDA    LRG1
      RET
;
; TABLE CALL ADD. AREA
;
      ORG    0FFC0H ; TCALL ADDRESS AREA
      DW    FUNC_A
      DW    FUNC_B
  
```

The interrupt causes the CPU to jump to specific location, where it commences the execution of the service routine. The External interrupt 0, for example, is assigned to location 0FFFC_H. The interrupt service locations spaces 2-byte interval: 0FFFA_H and 0FFFB_H for External Interrupt 1, 0FFFC_H and 0FFFD_H for External Interrupt 0, etc.

Any area from 0FF00_H to 0FFFF_H, if it is not going to be used, its service location is available as general purpose Program Memory.

Address	Vector Area Memory
0FFE0 _H	Basic Interval Timer
E2	Watchdog Timer Interrupt
E4	A/D Converter
E6	-
E8	Timer/Counter 3 Interrupt
EA	Timer/Counter 2 Interrupt
EC	Timer/Counter 1 Interrupt
EE	Timer/Counter 0 Interrupt
F0	Serial Input/Output (SIO)
F2	UART Tx interrupt
F4	UART Rx interrupt
F6	External Interrupt 3
F8	External Interrupt 2
FA	External Interrupt 1
FC	External Interrupt 0
FE	RESET

8.3 Data Memory

Figure 8-1 shows the internal Data Memory space available. Data Memory is divided into three groups, a user RAM, control registers, and Stack memory.

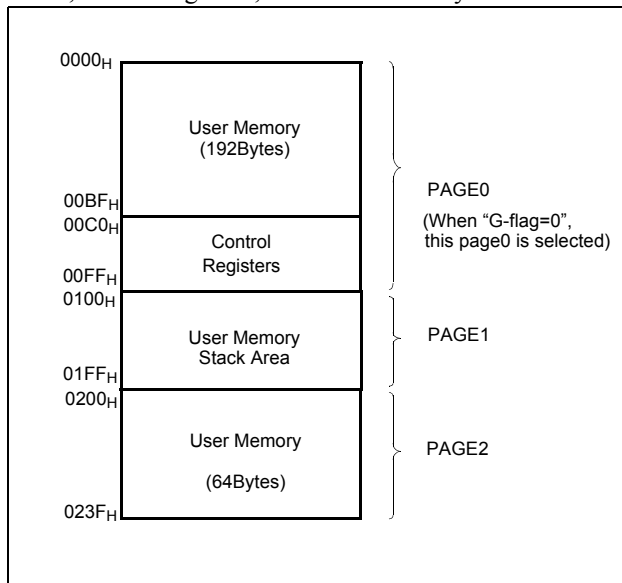

Figure 8-1 Data Memory Map

User Memory

The MC80F0304/0308/0316 has 256×8 bits for the user memory (RAM). RAM pages are selected by RPR (See Figure 8-2).

Note: After setting RPR(RAM Page Select Register), be sure to execute SETG instruction. When executing CLRG instruction, be selected PAGE0 regardless of RPR.

Control Registers

The control registers are used by the CPU and Peripheral function blocks for controlling the desired operation of the device. Therefore these registers contain control and status

bits for the interrupt system, the timer/ counters, analog to digital converters and I/O ports. The control registers are in address range of 0C0H to 0FFH.

Note that unoccupied addresses may not be implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have an indeterminate effect.

More detailed informations of each register are explained in each peripheral section.

Note: Write only registers can not be accessed by bit manipulation instruction. Do not use read-modify-write instruction. Use byte manipulation instruction, for example "LDM".

Example; To write at CKCTRL

```
LDM CKCTRL, #0AH ;Divide ratio(+32)
```

Stack Area

The stack provides the area where the return address is saved before a jump is performed during the processing routine at the execution of a subroutine call instruction or the acceptance of an interrupt.

When returning from the processing routine, executing the subroutine return instruction [RET] restores the contents of the program counter from the stack; executing the interrupt return instruction [RETI] restores the contents of the program counter and flags.

The save/restore locations in the stack are determined by the stack pointed (SP). The SP is automatically decreased after the saving, and increased before the restoring. This means the value of the SP indicates the stack location number for the next save. Refer to Figure 8-4 on page 18.

Figure 8-2 RPR(RAM Page Select Register)

Address	Register Name	Symbol	R/W	Initial Value								Addressing Mode	
				7	6	5	4	3	2	1	0

Table 8-1 Control Registers

1. The 'byte, bit' means registers are controlled by both bit and byte manipulation instruction. Caution) The R/W register except T1PDR and T3PDR are both can be byte and bit manipulated.
2. The 'byte' means registers are controlled by only byte manipulation instruction. Do not use bit manipulation instruction such as SET1, CLR1 etc. If bit manipulation instruction is used on these registers, content of other seven bits are may varied to unwanted value.

*The mark of '-' means this bit location is reserved.

Address	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

0FEH	PU2	R2 Pull-up Selection Register							
0FFH	PU3	R3 Pull-up Selection Register							

Table 8-2 Control Register Function Description

1. The register BTR and CKCTLR are located at same address. Address ECH is read as BTR, written to CKCTLR.

Caution) The registers of dark-shaded area can not be accessed by bit manipulation instruction such as "SET1, CLR1", but should be accessed by register operation instruction such as "LDM dp,#imm".

8.4 Addressing Mode

The MC8 series MCU uses six addressing modes;

- Register addressing
- Immediate addressing
- Direct page addressing
- Absolute addressing
- Indexed addressing
- Register-indirect addressing

8.4.1 Register Addressing

Register addressing accesses the A, X, Y, C and PSW.

8.4.2 Immediate Addressing → #imm

In this mode, second byte (operand) is accessed as a data immediately.

Example:

```
0435   ADC   #35H
```

When G-flag is 1, then RAM address is defined by 16-bit address which is composed of 8-bit RAM paging register (RPR) and 8-bit immediate data.

Example: G=1

```
E45535  LDM   35H, #55H
```

8.4.3 Direct Page Addressing → dp

In this mode, a address is specified within direct page.

Example; G=0

```
C535   LDA   35H           ;A ←RAM[35H]
```

8.4.4 Absolute Addressing → !abs

Absolute addressing sets corresponding memory data to Data, i.e. second byte (Operand I) of command becomes lower level address and third byte (Operand II) becomes upper level address.

With 3 bytes command, it is possible to access to whole memory area.

ADC, AND, CMP, CMPX, CMPY, EOR, LDA, LDX, LDY, OR, SBC, STA, STX, STY

Example;

```
0735F0  ADC   !0F035H     ;A ←ROM[0F035H]
```

The operation within data memory (RAM)
ASL, BIT, DEC, INC, LSR, ROL, ROR

Example; Addressing accesses the address 0135H regardless of G-flag.

```
983501 INC !0135H ;A ←ROM[135H]
```

8.4.5 Indexed Addressing

X indexed direct page (no offset) →{X}

In this mode, a address is specified by the X register.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA, XMA

Example; X=15H, G=1

```
D4 LDA {X} ;ACC←RAM[X].
```

X indexed direct page (8 bit offset) →dp+X

This address value is the second byte (Operand) of command plus the data of X-register. And it assigns the memory in Direct page.

ADC, AND, CMP, EOR, LDA, LDY, OR, SBC, STA, STY, XMA, ASL, DEC, INC, LSR, ROL, ROR

Example; G=0, X=0F5H

```
C645 LDA 45H+X
```

X indexed direct page, auto increment →{X}+

In this mode, a address is specified within direct page by the X register and the content of X is increased by 1.

LDA, STA

Example; G=0, X=35H

```
DB LDA {X}+
```

Y indexed direct page (8 bit offset) →dp+Y

This address value is the second byte (Operand) of command plus the data of Y-register, which assigns Memory in Direct page.

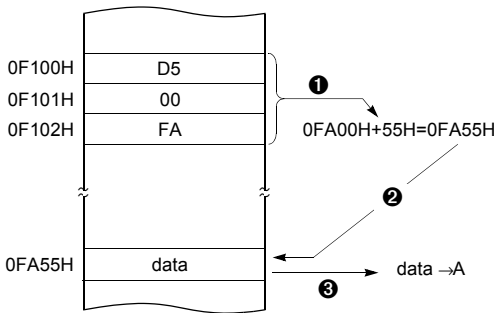

This is same with above (2). Use Y register instead of X.

Y indexed absolute →!abs+Y

Sets the value of 16-bit absolute address plus Y-register data as Memory. This addressing mode can specify memory in whole area.

Example; Y=55H

D500FA LDA !0FA00H+Y

1625 ADC [25H+X]

8.4.6 Indirect Addressing

Direct page indirect →[dp]

Assigns data address to use for accomplishing command which sets memory data (or pair memory) by Operand. Also index can be used with Index register X, Y.

JMP, CALL

Example; G=0

3F35 JMP [35H]

Y indexed indirect →[dp]+Y

Processes memory data as Data, assigned by the data [dp+1][dp] of 16-bit pair memory paired by Operand in Direct page plus Y-register data.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA

Example; G=0, Y=10H

1725 ADC [25H]+Y

DataSheet4U.com

DataSheet4U.com

X indexed indirect →[dp+X]

Processes memory data as Data, assigned by 16-bit pair memory which is determined by pair data [dp+X+1][dp+X] Operand plus X-register data in Direct page.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA

Example; G=0, X=10H

Absolute indirect →[!abs]

The program jumps to address specified by 16-bit absolute address.

JMP

Example; G=0

1F25E0 JMP [!0C025H]

9. I/O PORTS

The HMS83F012/022 has three ports (R0, R1 and R3). These ports pins may be multiplexed with an alternate function for the peripheral features on the device. All port can drive maximum 20mA of high current in output low state, so it can directly drive LED device.

All pins have data direction registers which can define these ports as output or input. A "1" in the port direction register configure the corresponding port pin as output. Conversely, write "0" to the corresponding bit to specify it as input pin. For example, to use the even numbered bit of R0 as output ports and the odd numbered bits as input ports, write "55H" to address 0C1H (R0 port direction register) during initial setting as shown in Figure 9-1 .

All the port direction registers in the HMS83F012/022 have 0 written to them by reset function. On the other hand,

its initial status is input.

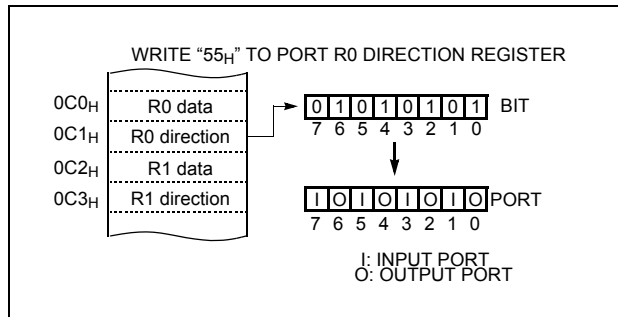

Figure 9-1 Example of port I/O assignment

9.1 R0 and R0IO register

R0 is an 8-bit CMOS bidirectional I/O port (address 0C0H). Each I/O pin can independently used as an input or an output through the R0IO register (address 0C1H). When R00 through R07 pins are used as input ports, an on-chip pull-up resistor can be connected to them in 1-bit units

with a pull-up selection register 0 (PU0). Each I/O pin of R0 port can be used to open drain output port by setting the corresponding bit of the open drain selection register 0 (R0OD).

Figure 9-2 R0 Port Register

In addition, Port R0 is multiplexed with various alternate functions. The port selection register PSR0 (address 0F8_H) and PSR1 (address 0F9_H) control the selection of alternate functions such as external interrupt 3 (INT3), external interrupt 2 (INT2), event counter input 0 (EC0), timer 0 output (T0O), timer 2 output (T2O) and event counter input 1 (EC1). When the alternate function is selected by writing "1" in the corresponding bit of PSR0 or PSR1, port pin can be used as a corresponding alternate features regardless of the direction register R0IO.

The ADC input channel 1~7 (AN1~AN7), SIO data input (SI), SIO data output (SOUT) and UART data input (RXD), UART data output (TXD) and UART clock input (ACLK) can be selected by setting ADCM(00EF_H), SIOM(00E2_H) and ASIMR(00E6_H) register to enable the corresponding peripheral operation and select operation mode.

Port Pin	Alternate Function
R00-	INT3 (External interrupt 3)
R01	SCK (SIO clock input/output) AN1(ADC Input channel 1) SI (SIO data input)
R02	AN2 (ADC Input channel 2) SOUT (SIO data output)
R03	AN3 (ADC Input channel 3) INT2 (External interrupt 2)
R04	AN4 (ADC Input channel 4) EC0 (Event counter input 0) RXD (UART data input)
R05	AN5 (ADC Input channel 5) T0O (Timer output 0) TXD (UART data output)
R06	AN6 (ADC Input channel 6) T2O (Timer output 2) ACLK (UART clock input)
R07	AN7 (ADC Input channel 7) EC1 (Event counter input 1)

9.2 R1 and R1IO register

R1 is a 5-bit CMOS bidirectional I/O port (address 0C2_H). Each I/O pin can independently used as an input or an output through the R1IO register (address 0C3_H). When R10 through R17 pins are used as input ports, an on-chip pull-up resistor can be connected to them in 1-bit units with a pull-up selection register 1 (PU1). Each I/O pin of R1 port can be used to open drain output port by setting the corresponding bit of the open drain selection register 1 (R1OD).

In addition, Port R1 is multiplexed with various alternate functions. The port selection register PSR0 (address 0F8_H) and PSR1 (address 0F9_H) control the selection of alternate functions such as Analog reference voltage input (AVREF), external interrupt 0 (INT0), external interrupt 1 (INT1), PWM 1 output (PWM1O), PWM 3 output (PWM3O) and buzzer output (BUZO). When the alternate function is selected by writing "1" in the corresponding bit of PSR0 or PSR1, port pin can be used as a corresponding alternate features regardless of the direction register R1IO.

The ADC input channel 0 (AN0) and channel 8(AN8) can be selected by setting ADCM(00EF_H) register to enable

ADC and select channel 0 and channel 8 .

Port Pin	Alternate Function

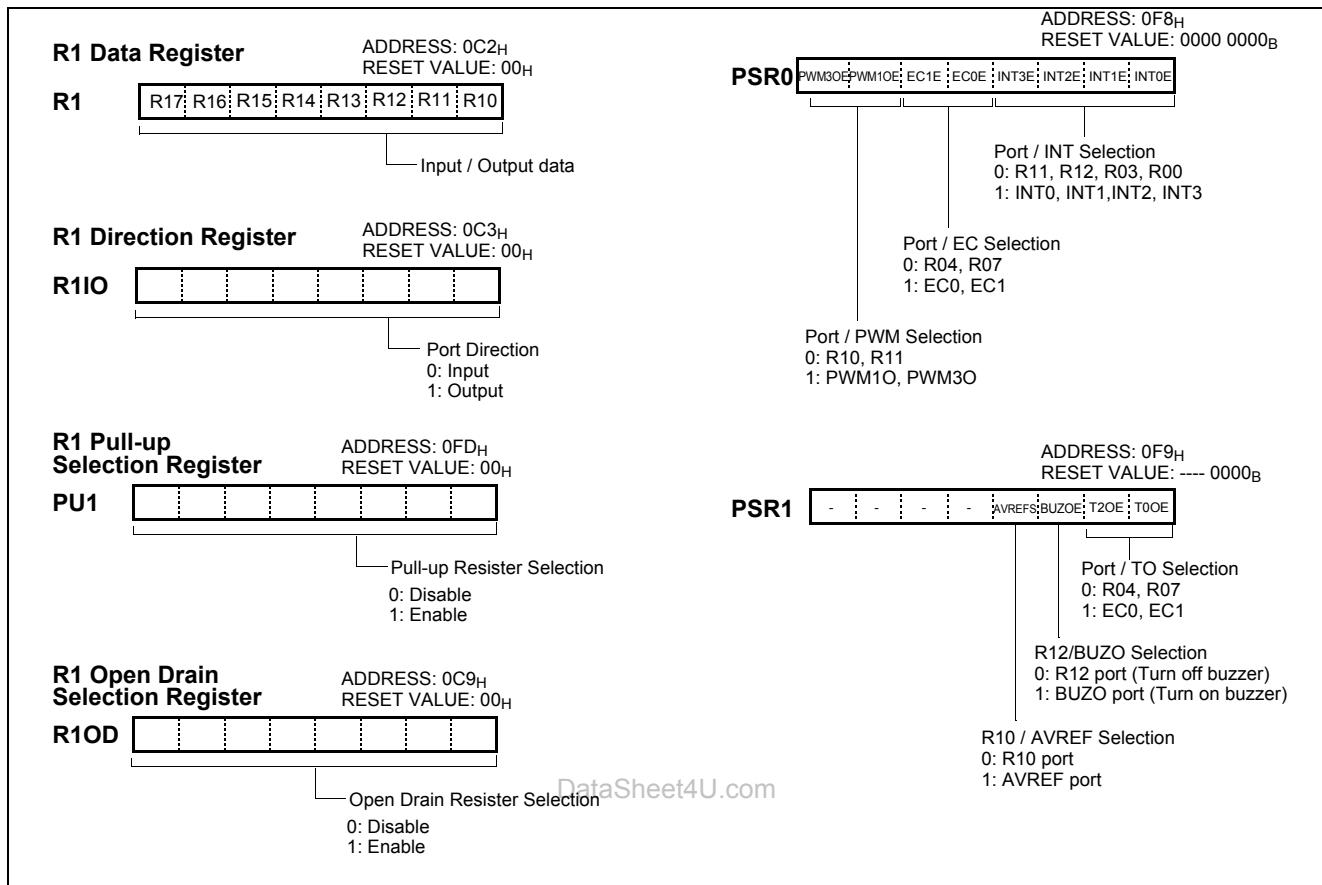

Figure 9-3 R1 Port Register

9.3 R2 and R2IO register

R2 is an 8-bit CMOS bidirectional I/O port (address 0C4_H). Each I/O pin can independently used as an input or an output through the R3IO register (address 0C5_H). When R20 through R27 pins are used as input ports, an on-chip pull-up resistor can be connected to them in 1-bit units with a pull-up selection register 2 (PU2). R20 through R27 pins can be used to open drain output port by setting the corresponding bit of the open drain selection register 2 (R2OD).

In addition, Port R2 is multiplexed with alternate functions. R23, R24, R25, and R26 can be used as ADC input channel 9 to 12 by setting ADCM to enable ADC and select channel 9 to 12.

Port Pin	Alternate Function
R20	-
R21	-

R27	-

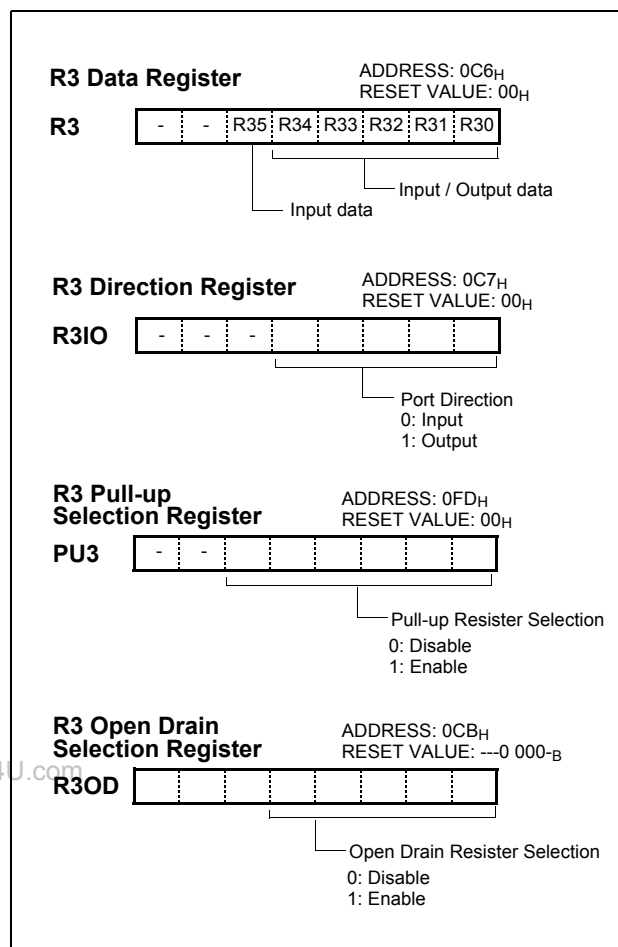

9.4 R3 and R3IO register

R3 is a 6-bit CMOS bidirectional I/O port (address 0C6_H). Each I/O pin (except R35) can independently used as an input or an output through the R3IO register (address 0C7_H). R35 is an input only port. When R30 through R35 pins are used as input ports, an on-chip pull-up resistor can be connected to them in 1-bit units with a pull-up selection register 3 (PU3). R30 through R34 pins can be used to open drain output port by setting the corresponding bit of the open drain selection register 1 (R3OD).

In addition, Port R3 is multiplexed with alternate functions. R30, R31, and R32 can be used as ADC input channel 13, 14 and 15 by setting ADCM to enable ADC and select channel 13, 14 and 15.

Port Pin	Alternate Function
R30	AN13 (ADC input channel 13)
R31	AN14 (ADC input channel 14)
R32	AN15 (ADC input channel 15)

R33, R34 and R35 is multiplexed with X_{IN}, X_{OUT}, and RE-SET pin.

10. CLOCK GENERATOR

As shown in Figure 10-1, the clock generator produces the basic clock pulses which provide the system clock to be supplied to the CPU and the peripheral hardware. It contains main-frequency clock oscillator. The system clock operation can be easily obtained by attaching a crystal or a ceramic resonator between the X_{IN} and X_{OUT} pin, respectively. The system clock can also be obtained from the external oscillator. In this case, it is necessary to input a external clock signal to the X_{IN} pin and open the X_{OUT} pin. There are no requirements on the duty cycle of the external clock signal, since the input to the internal clocking circuit-

ry is through a divide-by-two flip-flop, but minimum and maximum high and low times specified on the data sheet must be observed.

To the peripheral block, the clock among the not-divided original clock, clocks divided by 1, 2, 4, ..., up to 4096 can be provided. Peripheral clock is enabled or disabled by STOP instruction. The peripheral clock is controlled by clock control register (CKCTL). See "11. BASIC INTERVAL TIMER" on page 37 for details.

Figure 10-1 Block Diagram of Clock Generator

10.1 Oscillation Circuit

X_{IN} and X_{OUT} are the input and output, respectively, a inverting amplifier which can be set for use as an on-chip oscillator, as shown in Figure 10-2.

Figure 10-2 Oscillator Connections

Note: When using a system clock oscillator, carry out wiring in the broken line area in Figure 10-2 to prevent any effects from wiring capacities.

- Minimize the wiring length.
- Do not allow wiring to intersect with other signal conductors.
- Do not allow wiring to come near changing high current.
- Set the potential of the grounding position of the oscillator capacitor to that of V_{SS} . Do not ground to any ground pattern where high current is present.
- Do not fetch signals from the oscillator.

In addition, see Figure 10-3 for the layout of the crystal.

Figure 10-3 Layout of Oscillator PCB circuit

To drive the device from an external clock source, Xout should be left unconnected while Xin is driven as shown in Figure 10-4. There are no requirements on the duty cycle of the external clock signal, since the input to the internal clocking circuitry is through a divide-by-two flip-flop, but minimum and maximum high and low times specified on the data sheet must be observed.

Oscillation circuit is designed to be used either with a ceramic resonator or crystal oscillator. Since each crystal and ceramic resonator have their own characteristics, the user should consult the crystal manufacturer for appropriate values of external components.

Figure 10-4 External Clock Connections

In addition, the HMS83F012/022 has an ability for the external RC oscillated operation. It offers additional cost savings for **timing insensitive applications**. The RC oscillator frequency is a function of the supply voltage, the external resistor (R_{EXT}) and capacitor (C_{EXT}) values, and the operating temperature.

The user needs to take into account variation due to tolerance of external R and C components used.

Figure 10-5 shows how the RC combination is connected to the HMS83F012/022. External capacitor (C_{EXT}) can be

omitted for more cost saving. However, the characteristics of external R only oscillation are more variable than external RC oscillation.

Figure 10-5 RC Oscillator Connections

Figure 10-6 R Oscillator Connections

To use the RC oscillation, the CLK option of the configuration bits (20FFH) should be set to "EXRC or EXRCXO".

The oscillator frequency, divided by 4, is output from the Xout pin, and can be used for test purpose or to synchronize other logic.

In addition to external crystal/resonator and external RC/R oscillation, the HMS83F012/022 provides the internal 4MHz or 2MHz oscillation. The internal 4MHz/2MHz oscillation needs no external parts.

To use the internal 4MHz/2MHz oscillation, the CLK option of the configuration bits should be set to "IN4MCLK", "IN2MCLK", "IN4MCLKXO" or "IN2MCLKXO". For detail description on the configuration bits, refer to "23.. Device Configuration Area" on page 100

11. BASIC INTERVAL TIMER

The HMS83F012/022 has one 8-bit Basic Interval Timer that is free-run and can not stop. Block diagram is shown in Figure 11-1. In addition, the Basic Interval Timer generates the time base for watchdog timer counting. It also provides a Basic interval timer interrupt (BITIF).

The 8-bit Basic interval timer register (BITR) is increased every internal count pulse which is divided by prescaler. Since prescaler has divided ratio by 8 to 1024, the count rate is 1/8 to 1/1024 of the oscillator frequency. As the count overflow from FFH to 00H, this overflow causes the interrupt to be generated.

The Basic Interval Timer is controlled by the clock control register (CKCTRL) shown in Figure 11-2. If the RCWDT bit is set to "1", the clock source of the BITR is changed to the internal RC oscillation.

When write "1" to bit BTCL of CKCTRL, BITR register is cleared to "0" and restart to count-up. The bit BTCL becomes "0" after one machine cycle by hardware.

If the STOP instruction executed after writing "1" to bit RCWDT of CKCTRL, it goes into the internal RC oscillated watchdog timer mode. In this mode, all of the block is halted except the internal RC oscillator, Basic Interval Timer and Watchdog Timer. More detail informations are explained in Power Saving Function. The bit WDTON decides Watchdog Timer or the normal 7-bit timer. Source clock can be selected by lower 3 bits of CKCTRL.

BITR and CKCTRL are located at same address, and address 0F2_H is read as a BITR, and written to CKCTRL.

Note: All control bits of Basic interval timer are in CKCTRL register which is located at same address of BITR (address EC_H). Address EC_H is read as BITR, written to CKCTRL. Therefore, the CKCTRL can not be accessed by bit manipulation instruction.

Figure 11-1 Block Diagram of Basic Interval Timer

CKCTLR [2:0]	Source clock	Interrupt (overflow) Period (ms) @ $f_{XIN} = 8\text{MHz}$

12. WATCHDOG TIMER

The watchdog timer rapidly detects the CPU malfunction such as endless looping caused by noise or the like, and resumes the CPU to the normal state. The watchdog timer signal for detecting malfunction can be selected either a reset CPU or a interrupt request.

When the watchdog timer is not being used for malfunction detection, it can be used as a timer to generate an interrupt at fixed intervals.

The watchdog timer has two types of clock source. The first type is an on-chip RC oscillator which does not require any external components. This RC oscillator is separate from the external oscillator of the X_{IN} pin. It means that the watchdog timer will run, even if the clock on the X_{IN} pin of the device has been stopped, for example, by entering the STOP mode. The other type is a prescaled system clock.

The watchdog timer consists of 7-bit binary counter and the watchdog timer data register. When the value of 7-bit binary counter is equal to the lower 7 bits of WDTR, the interrupt request flag is generated. This can be used as Watchdog timer interrupt or reset the CPU in accordance with the bit WDTON.

The RC oscillated watchdog timer is activated by setting the bit RCWDT as shown below.

```
LDM      CKCTLR, #3FH; enable the RC-OSC WDT
LDM      WDTR, #0FFH ; set the WDT period
LDM      SSCR, #5AH ; ready for STOP mode
STOP     ; enter the STOP mode
NOP
NOP     ; RC-OSC WDT running
:
```

The RC-WDT oscillation period is vary with temperature, V_{DD} and process variations from part to part (approximately, 33~100uS). The following equation shows the RCWDT oscillated watchdog timer time-out.

$$T_{RCWDT} = CLK_{RCWDT} \times 2^8 \times WDTR + (CLK_{RCWDT} \times 2^8) / 2$$

where, $CLK_{RCWDT} = 33 \sim 100 \mu S$

In addition, this watchdog timer can be used as a simple 7-bit timer by interrupt WDTIF. The interval of watchdog timer interrupt is decided by Basic Interval Timer. Interval equation is as below.

$$T_{WDT} = (WDTR + 1) \times \text{Interval of BIT}$$

Note: Because the watchdog timer counter is enabled after clearing Basic Interval Timer, after the bit WDTON set to "1", maximum error of timer is depend on prescaler ratio of Basic Interval Timer. The 7-bit binary counter is cleared by setting WDTCL(bit7 of WDTR) and the WDTCL is cleared automatically after 1 machine cycle.

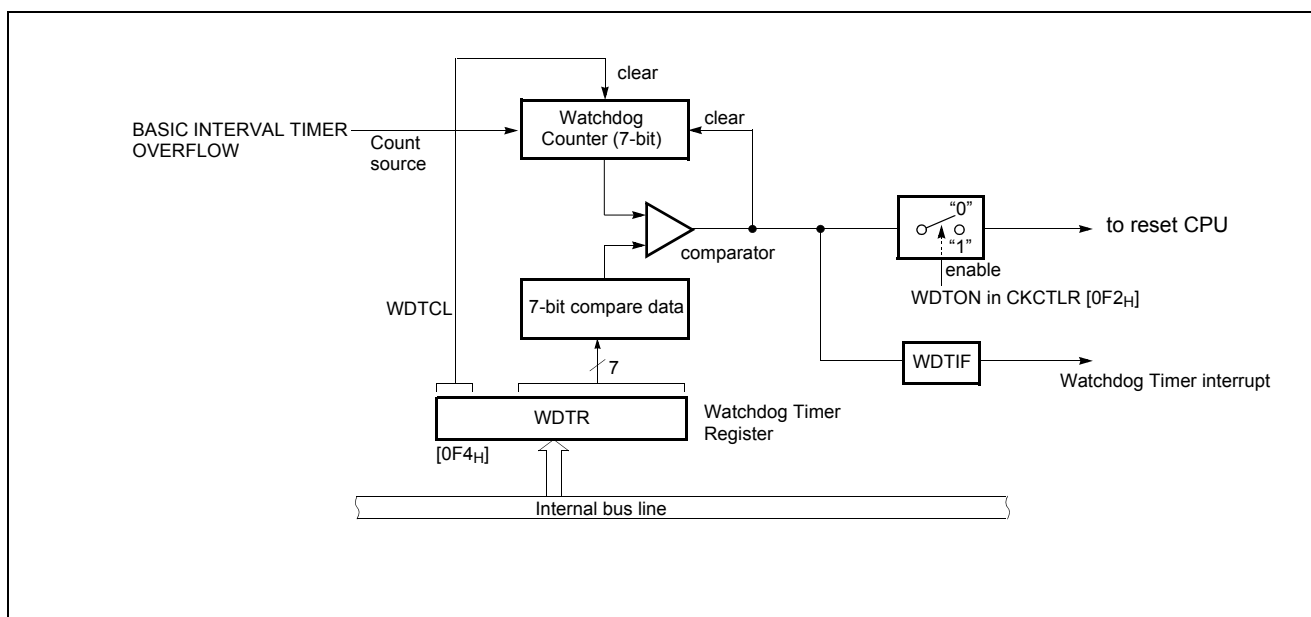

Figure 12-1 Block Diagram of Watchdog Timer

Watchdog Timer Control

Figure 12-2 shows the watchdog timer control register. The watchdog timer is automatically disabled after reset.

The CPU malfunction is detected during setting of the detection time, selecting of output, and clearing of the binary counter. Clearing the binary counter is repeated within the detection time.

If the malfunction occurs for any cause, the watchdog timer

output will become active at the rising overflow from the binary counters unless the binary counter is cleared. At this time, when $WDTON=1$, a reset is generated, which drives the \overline{RESET} pin to low to reset the internal hardware. When $WDTON=0$, a watchdog timer interrupt (WDTIF) is generated. The $WDTON$ bit is in register $CLKCTLR$.

The watchdog timer temporarily stops counting in the STOP mode, and when the STOP mode is released, it automatically restarts (continues counting).

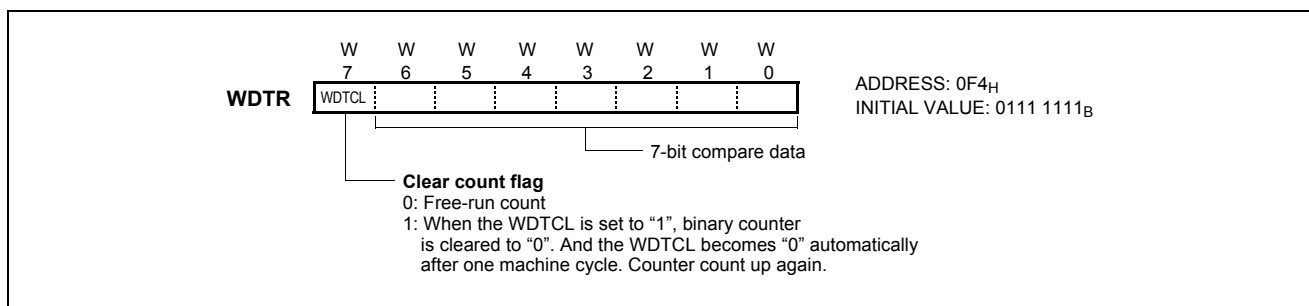

Figure 12-2 WDTR: Watchdog Timer Control Register

Example: Sets the watchdog timer detection time to 1 sec. at 4.194304MHz

```

LDM    CKCTLR, #3FH           ; Select 1/1024 clock source, WDTON ← 1, Clear Counter

LDM    WDTR, #08FH           ; Clear counter

```

Within WDT detection time

Within WDT detection time

Enable and Disable Watchdog

Watchdog timer is enabled by setting $WDTON$ (bit 4 in $CKCTLR$) to "1". $WDTON$ is initialized to "0" during reset and it should be set to "1" to operate after reset is released.

Example: Enables watchdog timer for Reset

```

:
LDM    CKCTLR, #xxx1_xxxxB; WDTON ← 1
:
:

```

The watchdog timer is disabled by clearing bit 4 ($WDTON$) of $CKCTLR$. The watchdog timer is halted in STOP mode and restarts automatically after STOP mode is released.

Watchdog Timer Interrupt

The watchdog timer can be also used as a simple 7-bit timer by clearing bit4 of $CKCTLR$ to "0". The interval of watchdog timer interrupt is decided by Basic Interval Timer. Interval equation is shown as below.

$$T_{WDT} = (WDTR + 1) \times \text{Interval of BIT}$$

The stack pointer (SP) should be initialized before using the watchdog timer output as an interrupt source.

Example: 7-bit timer interrupt set up.

```

LDM    CKCTLR, #xxx0_xxxxB; WDTON ← 0
LDM    WDTR, #8FH           ; WDTCL ← 1

```

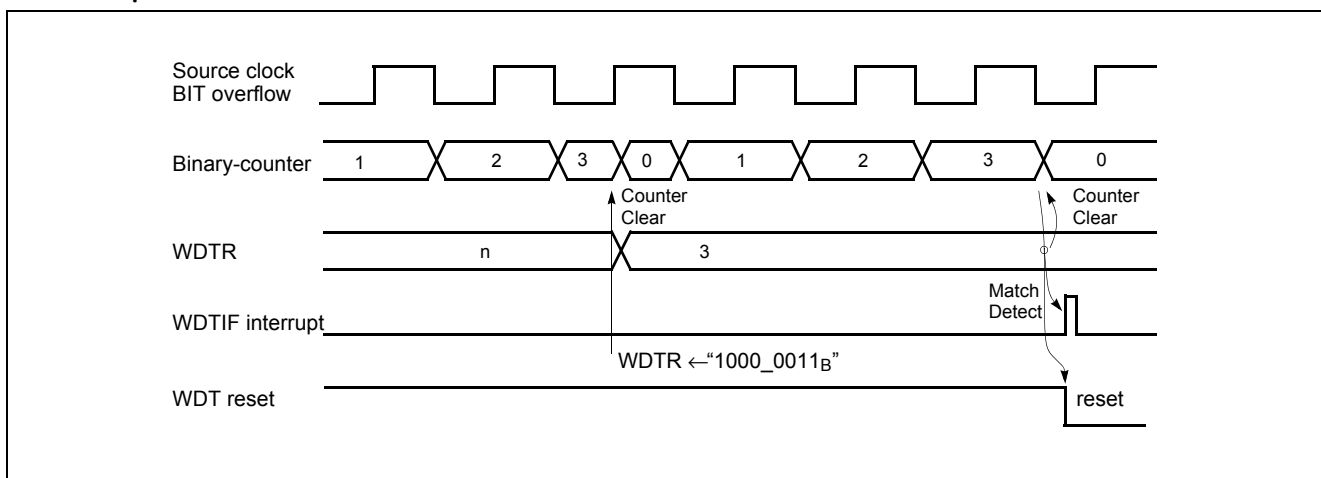

Figure 12-3 Watchdog timer Timing

If the watchdog timer output becomes active, a reset is generated, which drives the $\overline{\text{RESET}}$ pin low to reset the internal hardware.

The main clock oscillator also turns on when a watchdog timer reset is generated in sub clock mode.

13. TIMER/EVENT COUNTER

TheHMS83F012/022 has Four Timer/Counter registers. Each module can generate an interrupt to indicate that an event has occurred (i.e. timer match).

Timer 0 and Timer 1 are can be used either two 8-bit Timer/Counter or one 16-bit Timer/Counter with combine them. Also Timer 2 and Timer 3 are same. Timer 4 is 16-bit Timer/Counter.

In the “timer” function, the register is increased every internal clock input. Thus, one can think of it as counting internal clock input. Since a least clock consists of 2 and most clock consists of 2048 oscillator periods, the count rate is 1/2 to 1/2048 of the oscillator frequency.

In the “counter” function, the register is increased in response to a 0-to-1 (rising edge) transition at its corresponding external input pin, EC0 or EC1.

In addition the “capture” function, the register is increased

in response external or internal clock sources same with timer or counter function. When external clock edge input, the count register is captured into Timer data register correspondingly. When external clock edge input, the count register is captured into capture data register CDRx.

Timer 0 and Timer 1 is shared with "PWM" function and "Compare output" function. It has six operating modes: "8-bit timer/counter", "16-bit timer/counter", "8-bit capture", "16-bit capture", "8-bit compare output", and "10-bit PWM" which are selected by bit in Timer mode register TM0 and TM1 as shown in Table 13-1, Figure 13-1 .

Timer 2 and Timer 3 is shared with "PWM" function and "Compare output" function. It has six operating modes: "8-bit timer/counter", "16-bit timer/counter", "8-bit capture", "16-bit capture", "8-bit compare output", and "10-bit PWM" which are selected by bit in Timer mode register TM2 and TM3 as shown in Table 13-2, Figure 13-2 .

13.1 8-bit Timer / Counter Mode

The HMS83F012/022 has four 8-bit Timer/Counters, Timer 0, Timer 1, Timer 2, Timer 3. The Timer 0, Timer 1 are shown in Figure 13-3 and Timer 2, Timer 3 are shown in Figure 13-4.

The “timer” or “counter” function is selected by control registers TM0, TM1, TM2, TM3 as shown in Figure 13-1. To use as an 8-bit timer/counter mode, bit CAP0, CAP1, CAP2, or CAP3 of TMx should be cleared to “0” and 16BIT and PWM1E or PWM3E of TM1 or TM3 should be

cleared to “0” (Figure 13-3). These timers have each 8-bit count register and data register. The count register is increased by every internal or external clock input. The internal clock has a prescaler divide ratio option of 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048 or external clock (selected by control bits TxCK0, TxCK1, TxCK2 of register TMx).

These timers have each 8-bit count register and data regis-

ter. The count register is increased by every internal or external clock input. The internal clock has a prescaler divide ratio option of 2, 4, 8, 32, 128, 512, 2048 selected by control bits T0CK[2:0] of register TM0 or 1, 2, 8 selected by control bits T1CK[1:0] of register TM1, or 2, 4, 8, 16, 64, 256, 1024 selected by control bits T2CK[2:0] of register TM2, or 1, 4, 16 selected by control bits T3CK[1:0] of register TM3. In the Timer 0, timer register T0 increases from 00H until it matches TDR0 and then reset to 00H. The match output of Timer 0 generates Timer 0 interrupt (latched in T0IF bit).

In counter function, the counter is increased every 0-to-1 (rising edge) transition of EC0 pin. In order to use counter function, the bit EC0 of the Port Selection Register (PSR0.4) is set to "1". The Timer 0 can be used as a counter by pin EC0 input, but Timer 1 can not. Likewise, In order to use Timer2 as counter function, the bit EC1 of the Port Selection Register (PSR0.5) is set to "1". The Timer 2 can be used as a counter by pin EC1 input, but Timer 3 can not.

13.1.1 8-bit Timer Mode

In the timer mode, the internal clock is used for counting up. Thus, you can think of it as counting internal clock input. The contents of TDR_n are compared with the contents of up-counter, T_n. If match is found, a timer *n* interrupt (T_nIF) is generated and the up-counter is cleared to 0. Counting up is resumed after the up-counter is cleared.

As the value of TDR_n is changeable by software, time interval is set as you want.

Figure 13-5 Timer Mode Timing Chart

Example: Make 1ms interrupt using by Timer0 at 4MHz

```
LDM    TM0, #0FH    ; divide by 32
LDM    TDR0, #124  ; 8us x (124+1) = 1ms
SET1   T0E         ; Enable Timer 0 Interrupt
EI     ; Enable Master Interrupt
```

When $\left\{ \begin{array}{l} \text{TM0} = 0000\ 1111_B \text{ (8-bit Timer mode, Prescaler divide ratio} = 32) \\ \text{TDR0} = 124_D = 7C_H \\ f_{XIN} = 4 \text{ MHz} \end{array} \right.$

$$\text{INTERRUPT PERIOD} = \frac{1}{4 \times 10^6 \text{ Hz}} \times 32 \times (124+1) = 1 \text{ ms}$$

Figure 13-6 Timer Count Example

13.1.2 8-bit Event Counter Mode

In this mode, counting up is started by an external trigger. This trigger means rising edge of the EC0 or EC1 pin input. Source clock is used as an internal clock selected with timer mode register TM0 or TM2. The contents of timer data register TDR_n (n = 0, 1, 2, 3) are compared with the contents of the up-counter T_n. If a match is found, a timer interrupt request flag T_nIF is generated, and the counter is cleared to "0". The counter is restart and count up continuously by every falling edge of the EC0 or EC1 pin input. The maximum frequency applied to the EC0 or EC1 pin is $f_{XIN}/2$ [Hz].

In order to use event counter function, the bit 4, 5 of the Port Selection Register PSR0(address 0F8H) is required to be set to "1".

After reset, the value of timer data register TDR_n is initialized to "0". The interval period of Timer is calculated as below equation.

$$\text{Period (sec)} = \frac{1}{f_{XIN}} \times 2 \times \text{Divide Ratio} \times (\text{TDR}_n + 1)$$

DataShee

13.2 16-bit Timer / Counter Mode

The Timer register is being run with all 16 bits. A 16-bit timer/counter register T0, T1 are incremented from 0000_H until it matches TDR0, TDR1 and then resets to 0000_H. The match output generates Timer 0 interrupt.

The clock source of the Timer 0 is selected either internal or external clock by bit T0CK[2:0]. In 16-bit mode, the bits T1CK[1:0] and 16BIT of TM1 should be set to "1" respectively as shown in Figure 13-9.

Likewise, A 16-bit timer/counter register T2, T3 are incremented from 0000_H until it matches TDR2, TDR3 and then resets to 0000_H. The match output generates Timer 2 interrupt.

The clock source of the Timer 2 is selected either internal or external clock by bit T2CK[2:0]. In 16-bit mode, the bits T3CK[1:0] and 16BIT of TM3 should be set to "1" respectively as shown in Figure 13-10.

Even if the Timer 0 (including Timer 1) is used as a 16-bit timer, the Timer 2 and Timer 3 can still be used as either two 8-bit timer or one 16-bit timer by setting the TM3. Reversely, even if the Timer 2 (including Timer 3) is used as a 16-bit timer, the Timer 0 and Timer 1 can still be used as 8-bit timer independently.

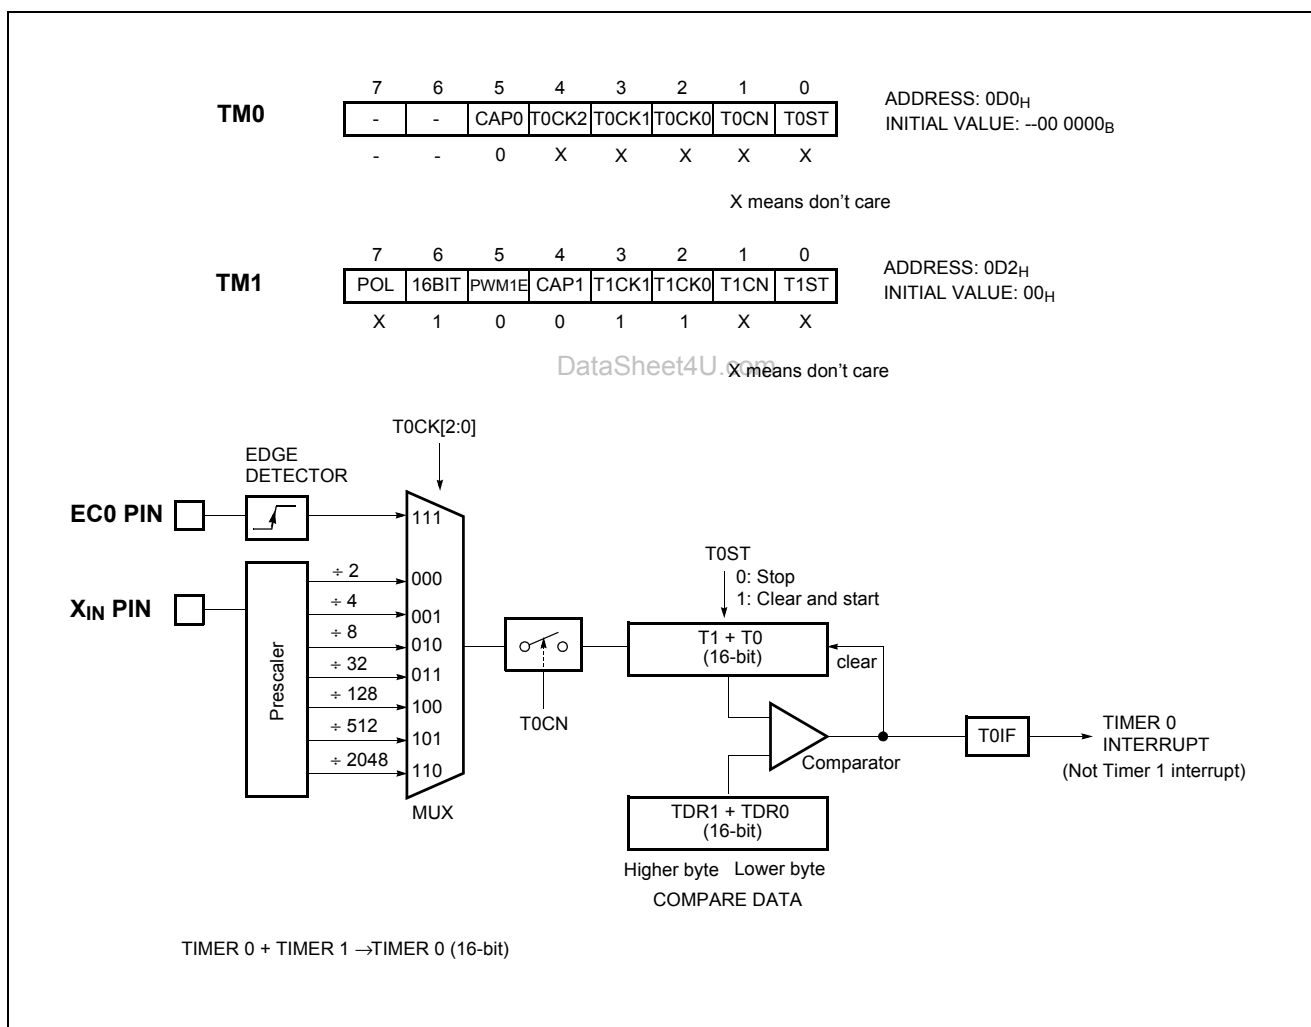

Figure 13-9 16-bit Timer/Counter for Timer 0, 1

Figure 13-10 16-bit Timer/Counter for Timer 2, 3

13.3 8-bit Compare Output (16-bit)

TheHMS83F012/022 has Timer Compare Output function. To pulse out, the timer match can go to port pin (T0O or T2O) as shown in Figure 13-3 or Figure 13-4. Thus, pulse out is generated by the timer match. These operation is implemented to pin, R05/AN5//T0O/TXD or R06/AN6/T2O/ACK.

In this mode, the bit T0OE or T2OE bit of Port Selection register1 (PSR1.0 or PSR1.1) should be set to "1". This pin

13.4 8-bit Capture Mode

The Timer 0 capture mode is set by bit CAP0 of timer mode register TM0 (bit CAP1 of timer mode register TM1 for Timer 1) as shown in Figure 13-11. Likewise, the Tim-

output the signal having a 50 : 50 duty square wave, and output frequency is same as below equation.

$$f_{COMP} = \frac{\text{Oscillation Frequency}}{2 \times \text{Prescaler Value} \times (TDR + 1)}$$

er 2 capture mode is set by bit CAP2 of timer mode register TM2 (bit CAP3 of timer mode register TM3 for Timer 3) as shown in Figure 13-12.

The Timer/Counter register is increased in response internal or external input. This counting function is same with normal timer mode, and Timer interrupt is generated when timer register T0 (T1, T2, T3) increases and matches TDR0 (TDR1, TDR2, TDR3).

This timer interrupt in capture mode is very useful when the pulse width of captured signal is more wider than the maximum period of Timer.

For example, in Figure 13-14, the pulse width of captured signal is wider than the timer data value (FF_H) over 2 times. When external interrupt is occurred, the captured value (13_H) is more little than wanted value. It can be obtained correct value by counting the number of timer overflow occurrence.

Timer/Counter still does the above, but with the added feature that a edge transition at external input INTx pin causes the current value in the Timer x register (T0, T1, T2, T3), to be captured into registers CDRx (CDR0, CDR1, CDR2, CDR3), respectively. After captured, Timer x register is cleared and restarts by hardware. It has three transition modes: "falling edge", "rising edge", "both edge" which are selected by interrupt edge selection register IEDS. Refer to "18.4 External Interrupt" on page 84. In addition, the transition at INTn pin generate an interrupt.

Note: The CDRn and TDRn are in same address. In the capture mode, reading operation is read the CDRn, not TDRn because path is opened to the CDRn.

13.5 16-bit Capture Mode

16-bit capture mode is the same as 8-bit capture, except that the Timer register is being run will 16 bits. The clock source of the Timer 0 is selected either internal or external clock by bit T0CK[2:0]. In 16-bit mode, the bits T1CK1, T1CK0, CAP1 and 16BIT of TM1 should be set to "1" respectively as shown in Figure 13-15 .

The clock source of the Timer 2 is selected either internal or external clock by bit T2CK[2:0]. In 16-bit mode, the bits T3CK1, T3CK0, CAP3 and 16BIT of TM3 should be set to "1" respectively as shown in Figure 13-16 .

13.6 PWM Mode

TheHMS83F012/022 has high speed PWM (Pulse Width Modulation) functions which shared with Timer1 or Timer3.

In PWM mode, R10 / PWM1O or R11 / PWM3O pin output up to a 10-bit resolution PWM output. These pins should be configured as a PWM output by setting "1" bit PWM1OE and PWM3OE in PSR0 register.

The period of the PWM1 output is determined by the T1PPR (T1 PWM Period Register) and T1PWHR[3:2] (bit3,2 of T1 PWM High Register) and the duty of the PWM output is determined by the T1PDR (T1 PWM Duty Register) and T3PWHR[1:0] (bit1,0 of T1 PWM High Register).

The period of the PWM3 output is determined by the T3PPR (T3 PWM Period Register) and T3PWHR[3:2] (bit3,2 of T3 PWM High Register) and the duty of the PWM output is determined by the T3PDR (T3 PWM Duty Register) and T3PWHR[1:0] (bit1,0 of T3 PWM High Register).

The user writes the lower 8-bit period value to the T1(3)PPR(and the higher 2-bit period value to the T1(3)PWHR[3:2]. And writes duty value to the T1(3)PDR and the T1(3)PWHR[1:0] same way.

The T1(3)PDR is configured as a double buffering for glitchless PWM output. In Figure 13-18 , the duty data is transferred from the master to the slave when the period data matched to the counted value. (i.e. at the beginning of next duty cycle)

PWM1(3) Period = [PWM1(3)HR[3:2]T(2)3PPR] X Source Clock

PWM1(3) Duty = [PWM3HR[1:0]T3PDR] X Source Clock

The relation of frequency and resolution is in inverse proportion. Table 13-3 shows the relation of PWM frequency vs. resolution.

If it needed more higher frequency of PWM, it should be

reduced resolution.

Resolution	Frequency		
	T1CK[1:0] = 00(250nS)	T1CK[1:0] = 01(500nS)	T1CK[1:0] = 10(2uS)
10-bit	3.9kHz	0.98kHz	0.49kHz
9-bit	7.8kHz	1.95kHz	0.97kHz
8-bit	15.6kHz	3.90kHz	1.95kHz
7-bit	31.2kHz	7.81kHz	3.90kHz

Table 13-3 PWM Frequency vs. Resolution at 4MHz

The bit POL of TM1 or TM3 decides the polarity of duty cycle.

If the duty value is set same to the period value, the PWM output is determined by the bit POL (1: High, 0: Low). And if the duty value is set to "00_H", the PWM output is determined by the bit POL (1: Low, 0: High).

It can be changed duty value when the PWM output. However the changed duty value is output after the current period is over. And it can be maintained the duty value at present output when changed only period value shown as Figure 13-20 . As it were, the absolute duty time is not changed in varying frequency. But the changed period value must greater than the duty value.

Note: If changing the Timer1 to PWM function, it should be stop the timer clock firstly, and then set period and duty register value. If user writes register values while timer is in operation, these register could be set with certain values.

Ex) Sample Program @4MHz 2uS

```
LDM TM1,#1010_1000b ; Set Clock & PWM3E

14. ANALOG TO DIGITAL CONVERTER

The analog-to-digital converter (A/D) allows conversion of an analog input signal to a corresponding 10-bit digital value. The A/D module has ten (eight for HMS83F012) analog inputs, which are multiplexed into one sample and hold. The output of the sample and hold is the input into the converter, which generates the result via successive approximation.

The analog reference voltage is selected to V_{DD} or AV_{ref} by setting of the bit $AVREFS$ in $PSR1$ register. If external analog reference AV_{ref} is selected, the analog input channel 0 ($AN0$) should not be selected to use. Because this pin is used to an analog reference of A/D converter.

The A/D module has three registers which are the control register $ADCM$ and A/D result register $ADCRH$ and $ADCRL$. The $ADCRH[7:6]$ is used as ADC clock source selection bits too. The register $ADCM$, shown in Figure 14-4, controls the operation of the A/D converter module. The port pins can be configured as analog inputs or digital I/O.

It is selected for the corresponding channel to be converted by setting $ADS[3:0]$. The A/D port is set to analog input port by $ADEN$ and $ADS[3:0]$ regardless of port I/O direction register. The port unselected by $ADS[3:0]$ operates as normal port.

Figure 14-1 A/D Converter Operation Flow

How to Use A/D Converter

The processing of conversion is start when the start bit $ADST$ is set to "1". After one cycle, it is cleared by hardware. The register $ADCRH$ and $ADCRL$ contains the results of the A/D conversion. When the conversion is completed, the result is loaded into the $ADCRH$ and $ADCRL$, the A/D conversion status bit $ADSF$ is set to "1", and the A/D interrupt flag $ADCIF$ is set. See Figure 14-1 for operation flow.

The block diagram of the A/D module is shown in Figure 14-3. The A/D status bit $ADSF$ is set automatically when A/D conversion is completed, cleared when A/D conversion is in process. The conversion time takes 13 times of conversion source clock. The conversion source clock should selected for the conversion time being more than $25\mu s$.

A/D Converter Cautions

(1) Input range of $AN0 \sim AN7$, $AN14$ and $AN15$

The input voltage of A/D input pins should be within the specification range. In particular, if a voltage above V_{DD} (or AV_{ref}) or below V_{SS} is input (even if within the absolute maximum rating range), the conversion value for that channel can not be indeterminate. The conversion values of the other channels may also be affected.

(2) Noise countermeasures

In order to maintain 10-bit resolution, attention must be paid to noise on pins V_{DD} (or AV_{ref}) and analog input pins ($AN0 \sim AN7$, $AN14$, $AN15$). Since the effect increases in proportion to the output impedance of the analog input source, it is recommended in some cases that a capacitor be connected externally as shown in Figure 14-2 in order to reduce noise. The capacitance is user-selectable and appropriately determined according to the target system.

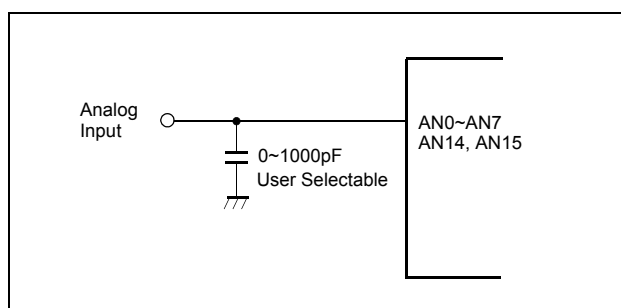

Figure 14-2 Analog Input Pin Connecting Capacitor

(3) I/O operation

The analog input pins AN0 ~ AN7, AN14 and AN15 also have function as input/output port pins. When A/D conversion is performed with any pin, be sure not to execute a PORT input instruction with the selected pin while conversion is in progress, as this may reduce the conversion resolution.

Also, if digital pulses are applied to a pin adjacent to the pin in the process of A/D conversion, the expected A/D conversion value may not be obtainable due to coupling noise. Therefore, avoid applying pulses to pins adjacent to

the pin undergoing A/D conversion.

(4) AV_{DD} pin input impedance

A series resistor string of approximately 5K Ω is connected between the AV_{REF} pin and the V_{SS} pin. Therefore, if the output impedance of the analog power source is high, this will result in parallel connection to the series resistor string between the AV_{REF} pin and the V_{SS} pin, and there will be a large analog supply voltage error

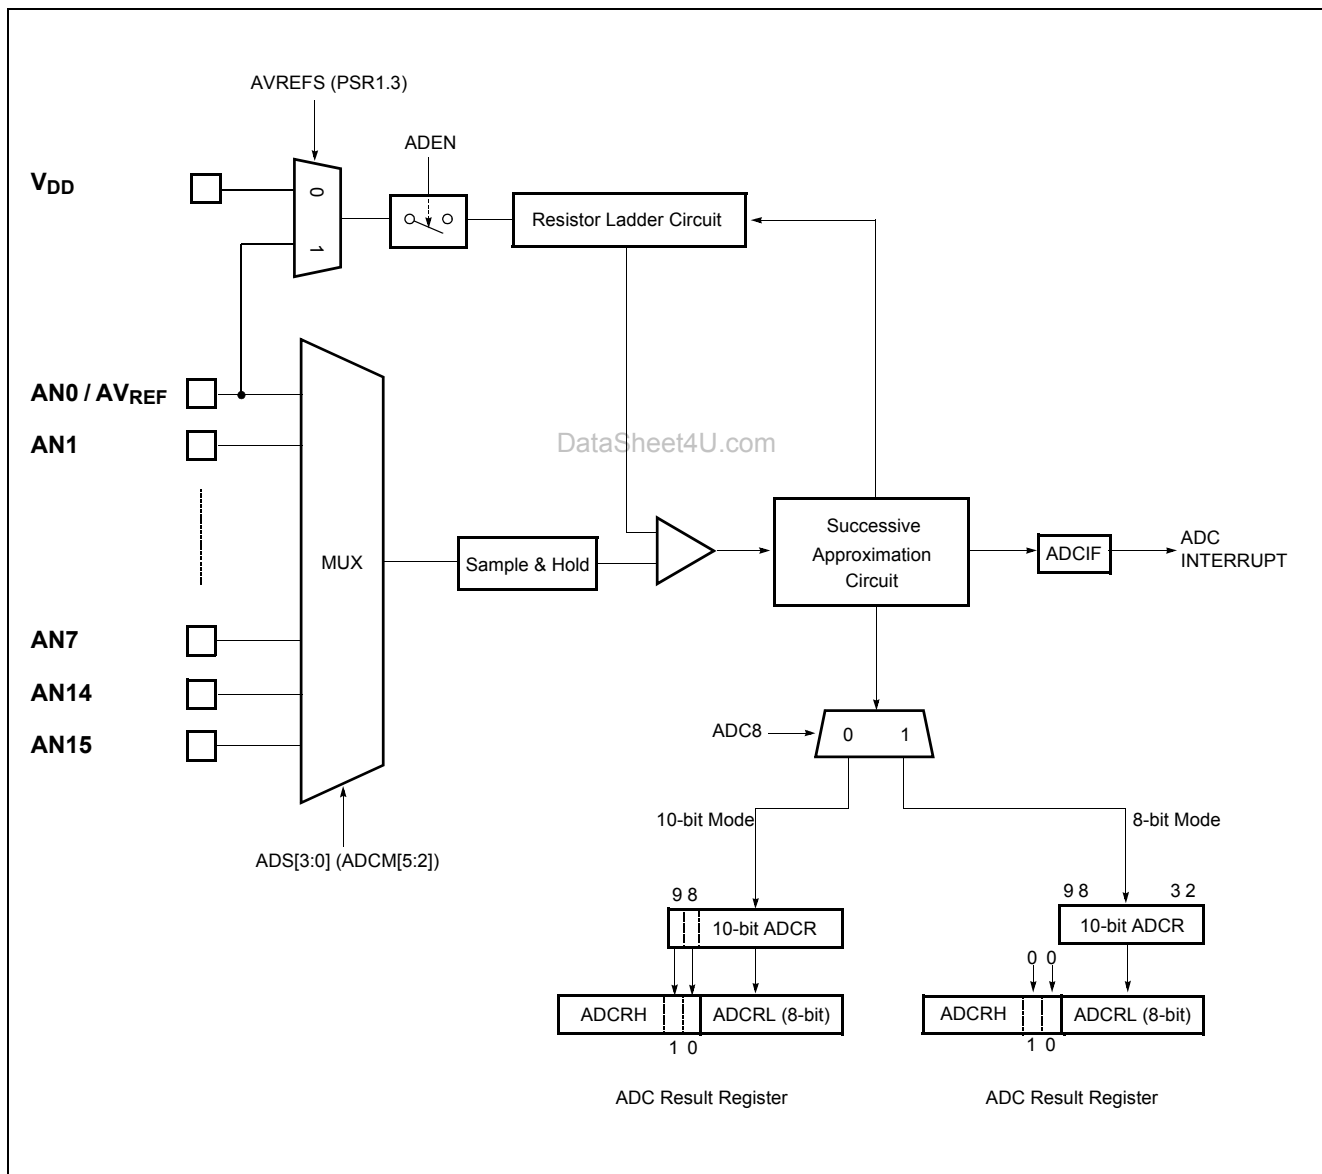

Figure 14-3 A/D Block Diagram

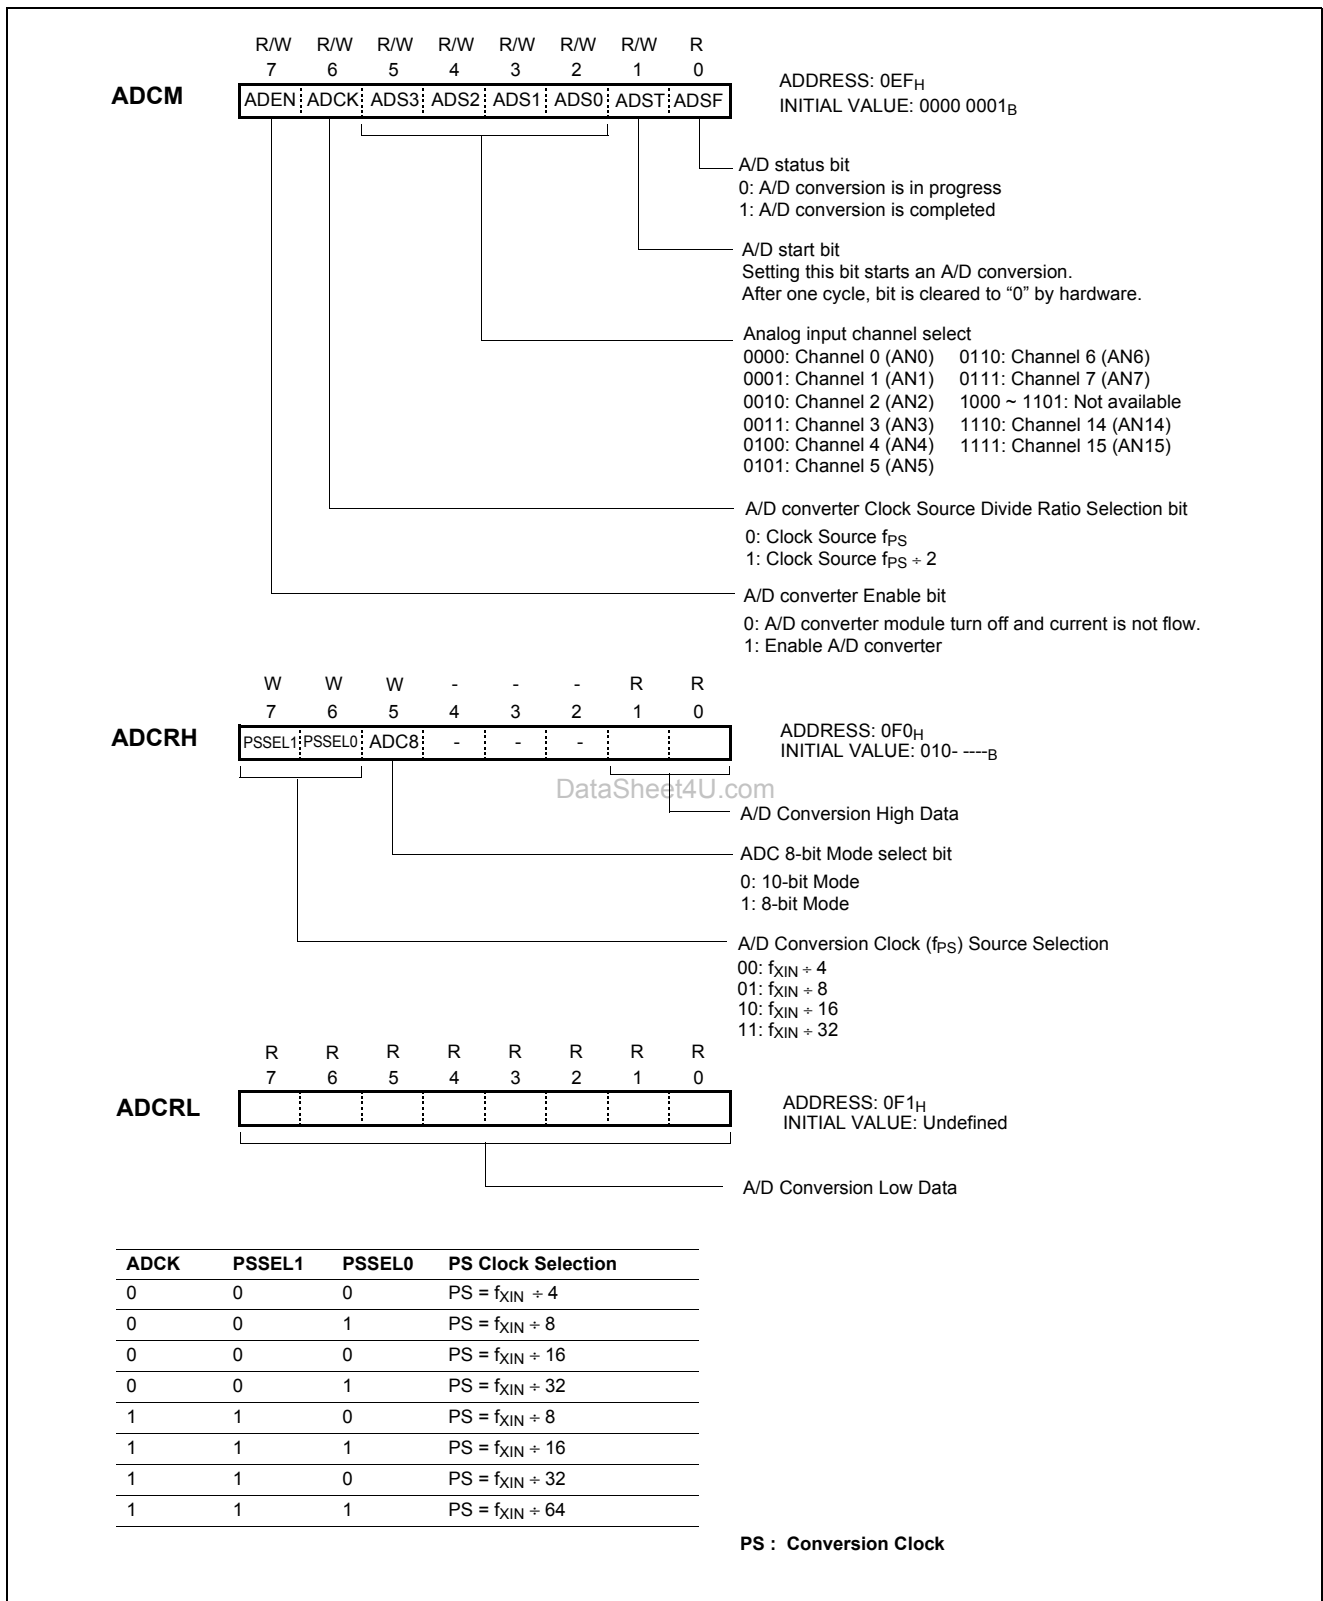

Figure 14-4 A/D Converter Control & Result Register

15. SERIAL INPUT/OUTPUT (SIO)

The serial Input/Output is used to transmit/receive 8-bit data serially. The Serial Input/Output (SIO) module is a serial interface useful for communicating with other peripheral of microcontroller devices. These peripheral devices may be serial EEPROMs, shift registers, display drivers, A/D converters, etc. This SIO is 8-bit clock synchronous type and consists of serial I/O data register, serial I/O mode register, clock selection circuit, octal counter and control

circuit as illustrated in Figure 15-1. The SO pin is designed to input and output. So the Serial I/O(SIO) can be operated with minimum two pin. Pin R00/SCK, R01/SI, and R02/SO pins are controlled by the Serial Mode Register. The contents of the Serial I/O data register can be written into or read out by software. The data in the Serial Data Register can be shifted synchronously with the transfer clock signal.

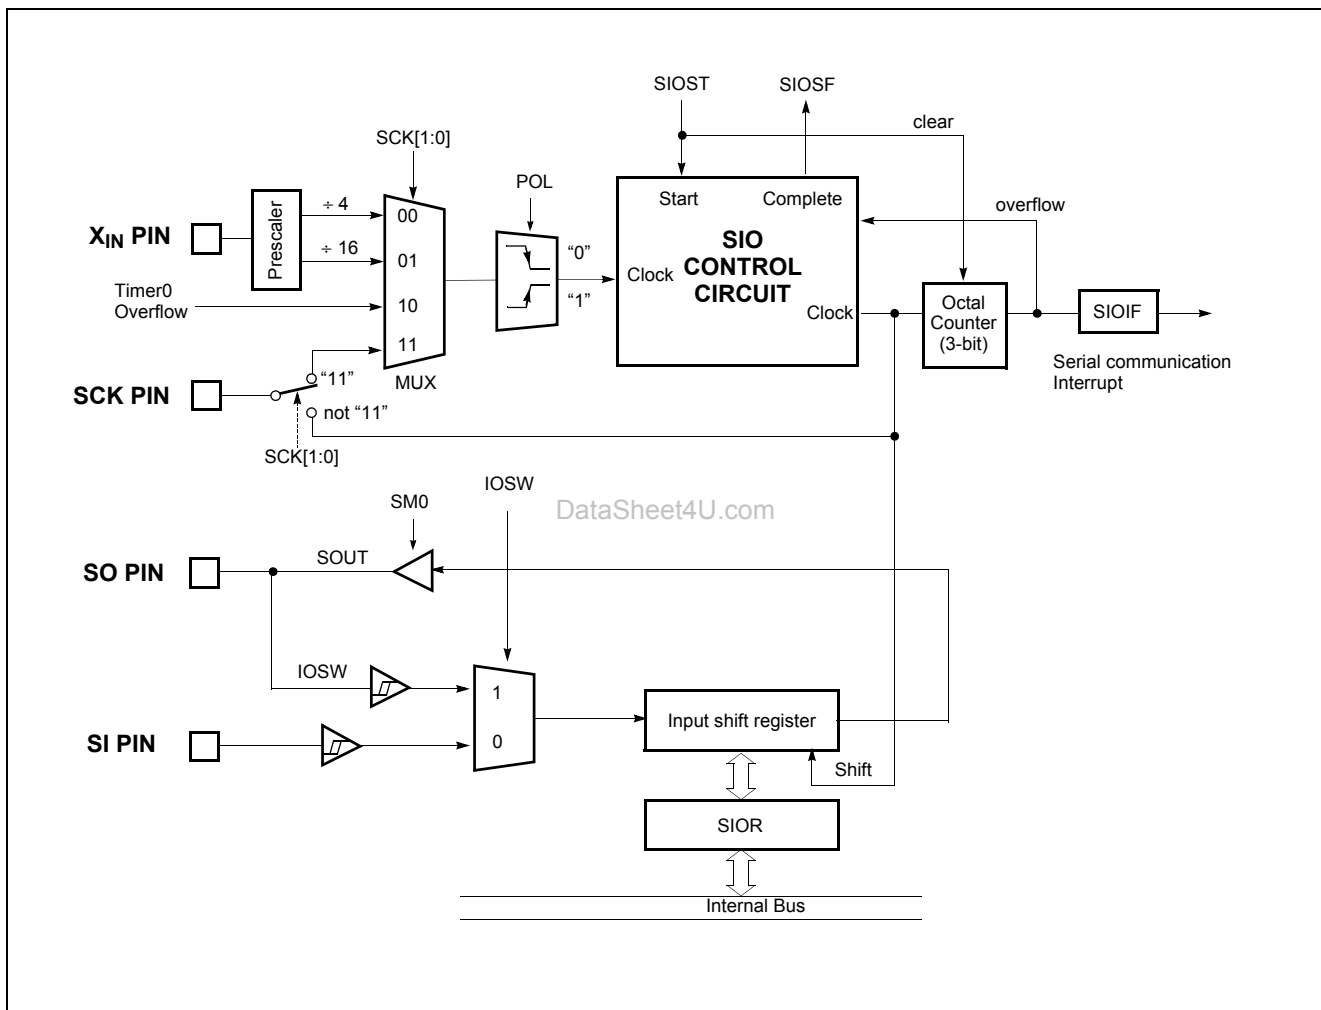

Figure 15-1 SIO Block Diagram

Serial I/O Mode Register (SIOM) controls serial I/O function. According to SCK1 and SCK0, the internal clock or external clock can be selected.

Serial I/O Data Register (SIOR) is an 8-bit shift register. First LSB is send or is received.

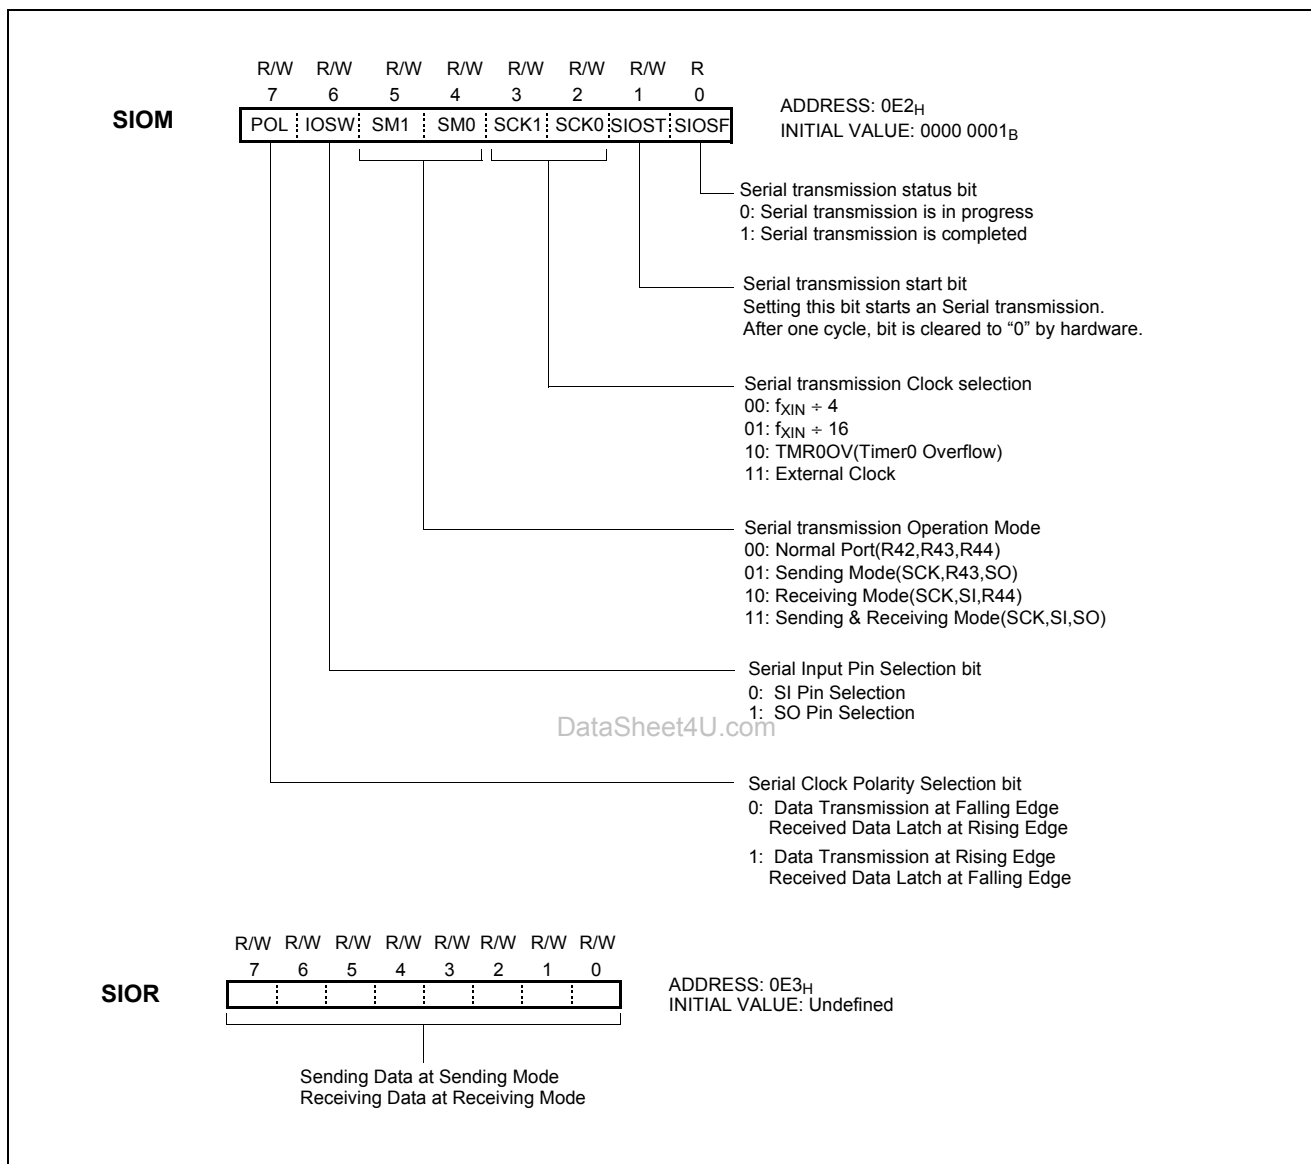

Figure 15-2 SIO Control Register

15.1 Transmission/Receiving Timing

The serial transmission is started by setting SIOST(bit1 of SIOM) to "1". After one cycle of SCK, SIOST is cleared automatically to "0". At the default state of POL bit clear, the serial output data from 8-bit shift register is output at falling edge of SCLK, and input data is latched at rising

edge of SCLK pin (Refer to Figure 15-3). When transmission clock is counted 8 times, serial I/O counter is cleared as '0'. Transmission clock is halted in "H" state and serial I/O interrupt (SIOIF) occurred.

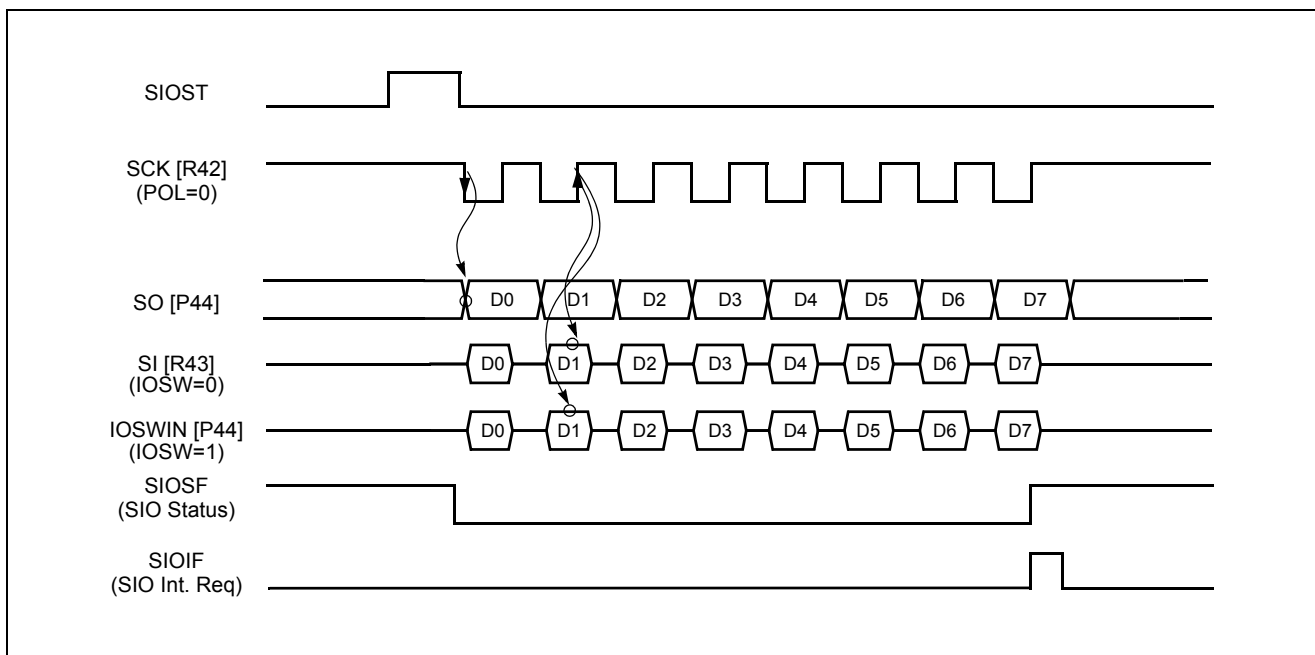

Figure 15-3 Serial I/O Timing Diagram at POL=0

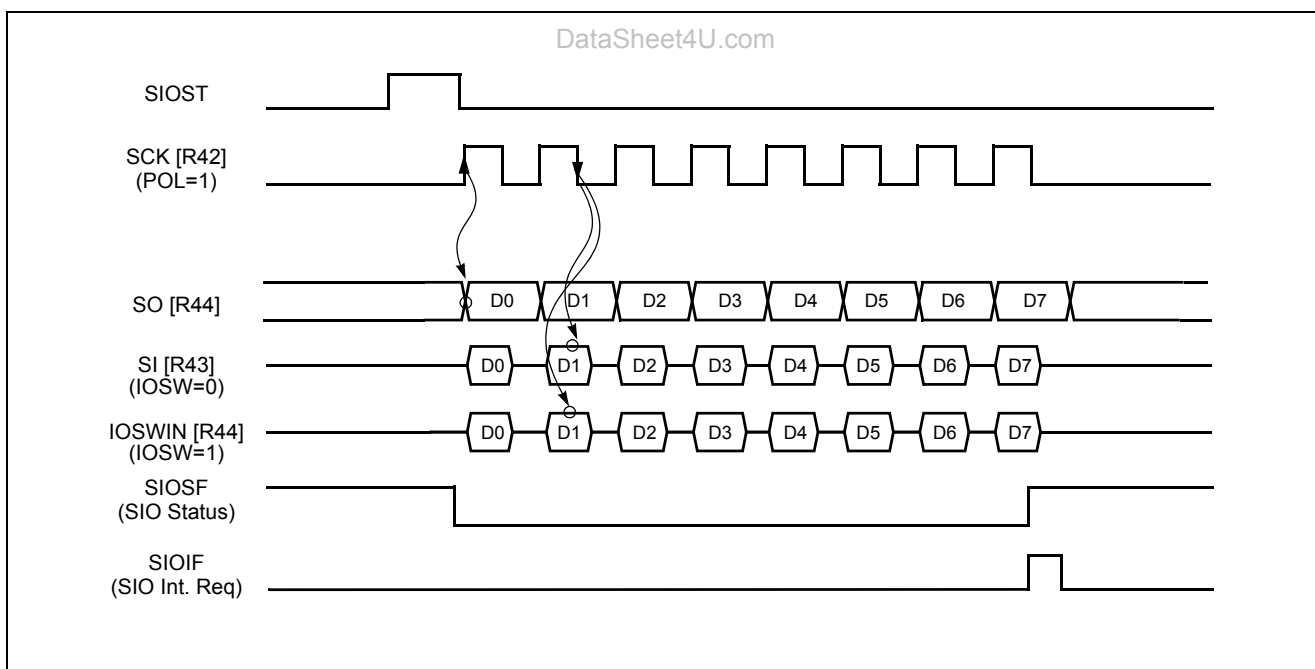

Figure 15-4 Serial I/O Timing Diagram at POL=1

15.2 The usage of Serial I/O

1. Select transmission/receiving mode.
2. In case of sending mode, write data to be send to SIOR.
3. Set SIOST to "1" to start serial transmission.
4. The SIO interrupt is generated at the completion of SIO and SIOIF is set to "1". In SIO interrupt service routine, correct transmission should be tested.
5. In case of receiving mode, the received data is acquired by reading the SIOR.

```
LDM    SIOR, #0AAh    ;set tx data
LDM    SIOM, #0011_1100b ;set SIO mode
NOP
LDM    SIOM, #0011_1110b ;SIO Start
```

Note: When external clock is used, the frequency should be less than 1MHz and recommended duty is 50%. If both transmission mode is selected and transmission is performed simultaneously, error may be occur.

15.3 The Method to Test Correct Transmission

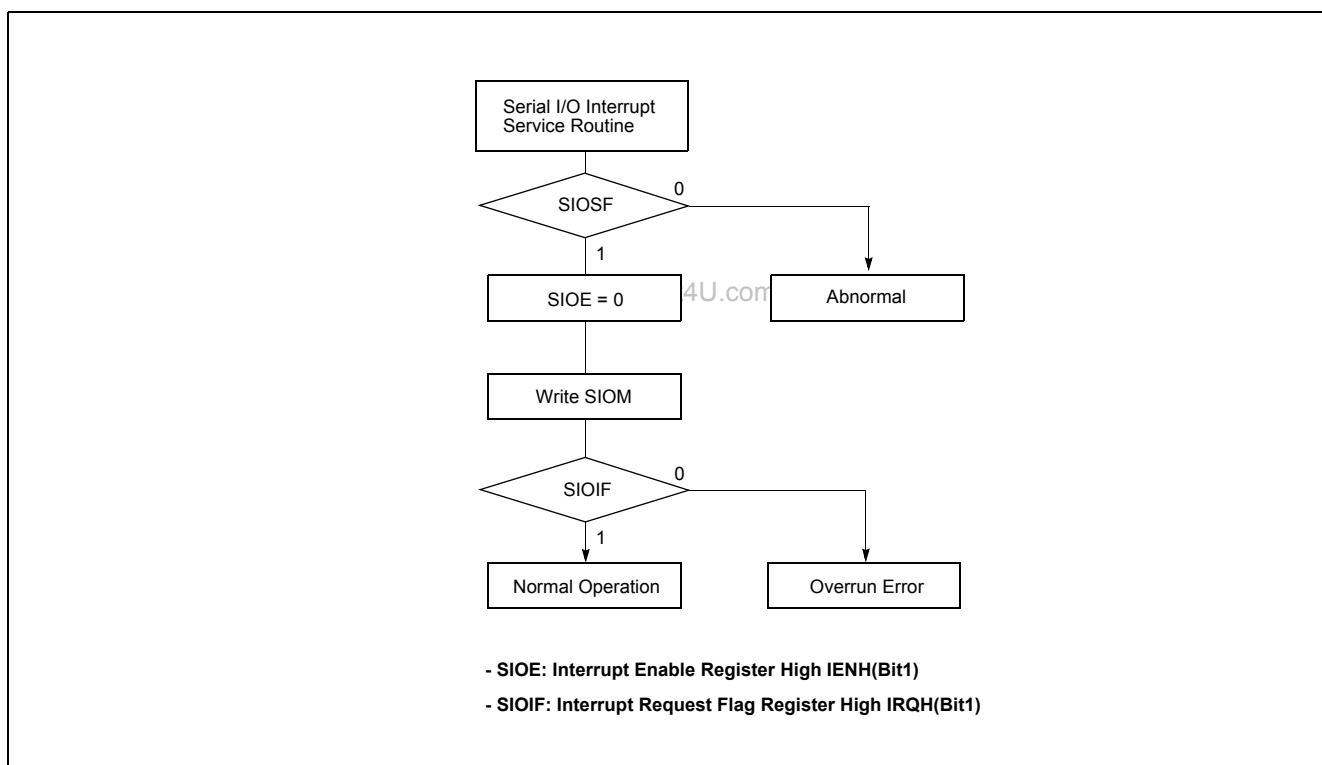

Figure 15-5 Serial IO Method to Test Transmission

16. UNIVERSAL ASYNCHRONOUS RECEIVER/TRANSMITTER (UART)

16.1 UART Serial Interface Functions

The Universal Asynchronous Receiver / Transmitter (UART) enables full-duplex operation wherein one byte of data after the start bit is transmitted and received. The on-chip baud rate generator dedicated to UART enables communications using a wide range of selectable baud rates. In addition, a baud rate can also be defined by dividing clocks input to the ACLK pin.

The UART driver consists of RXR, TXR, ASIMR, ASISR and BRGCR register. Universal asynchronous serial I/O mode (UART) can be selected by ASIMR register. Figure 16-1 shows a block diagram of the UART driver.

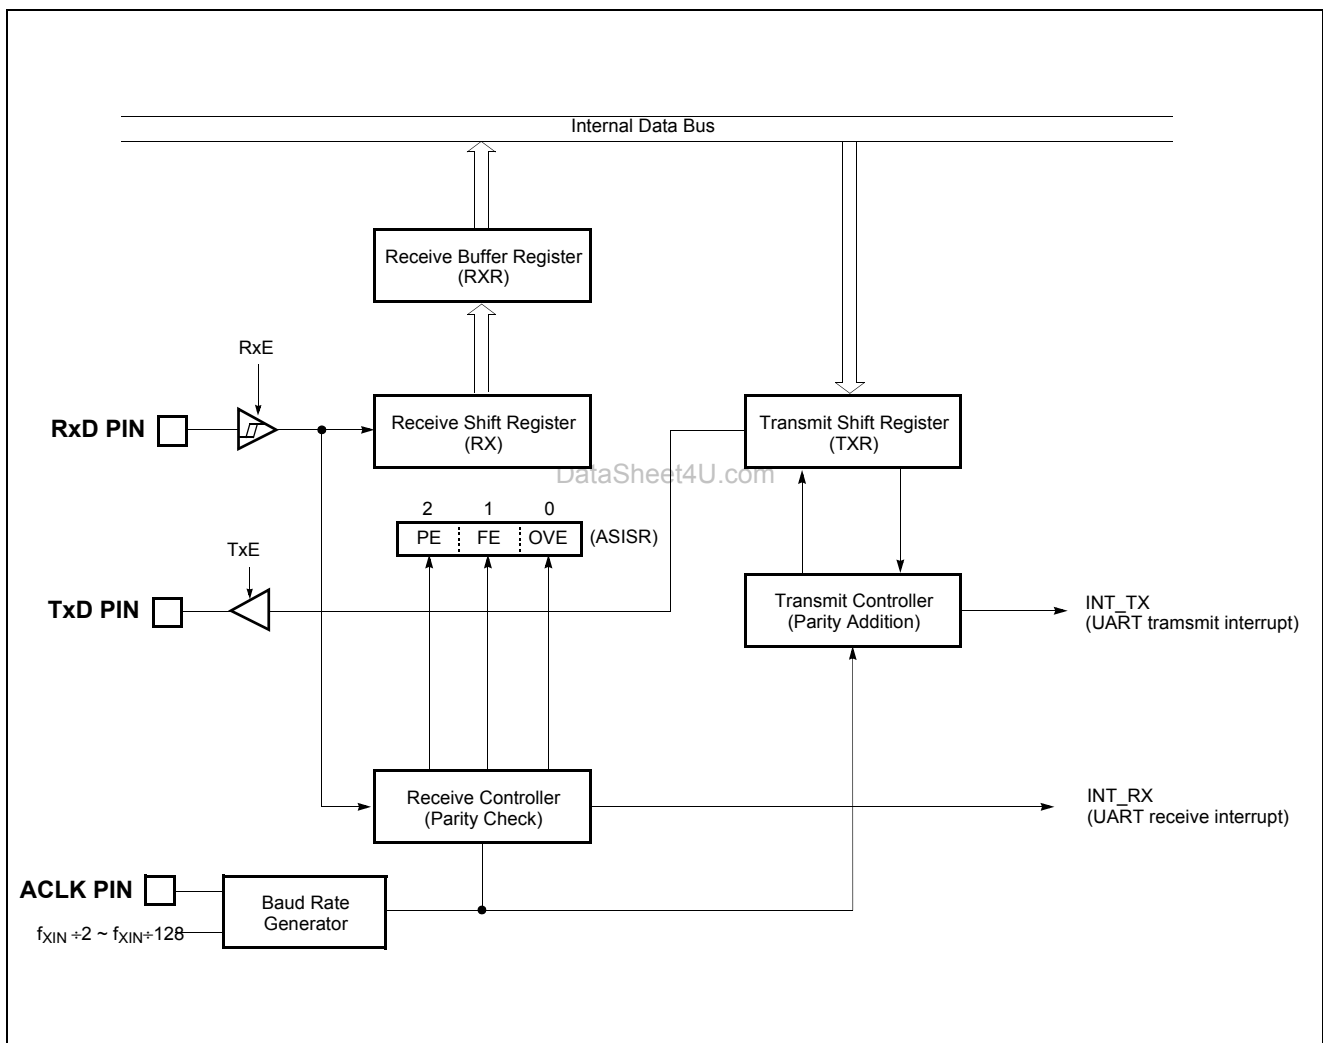

Figure 16-1 UART Block Diagram

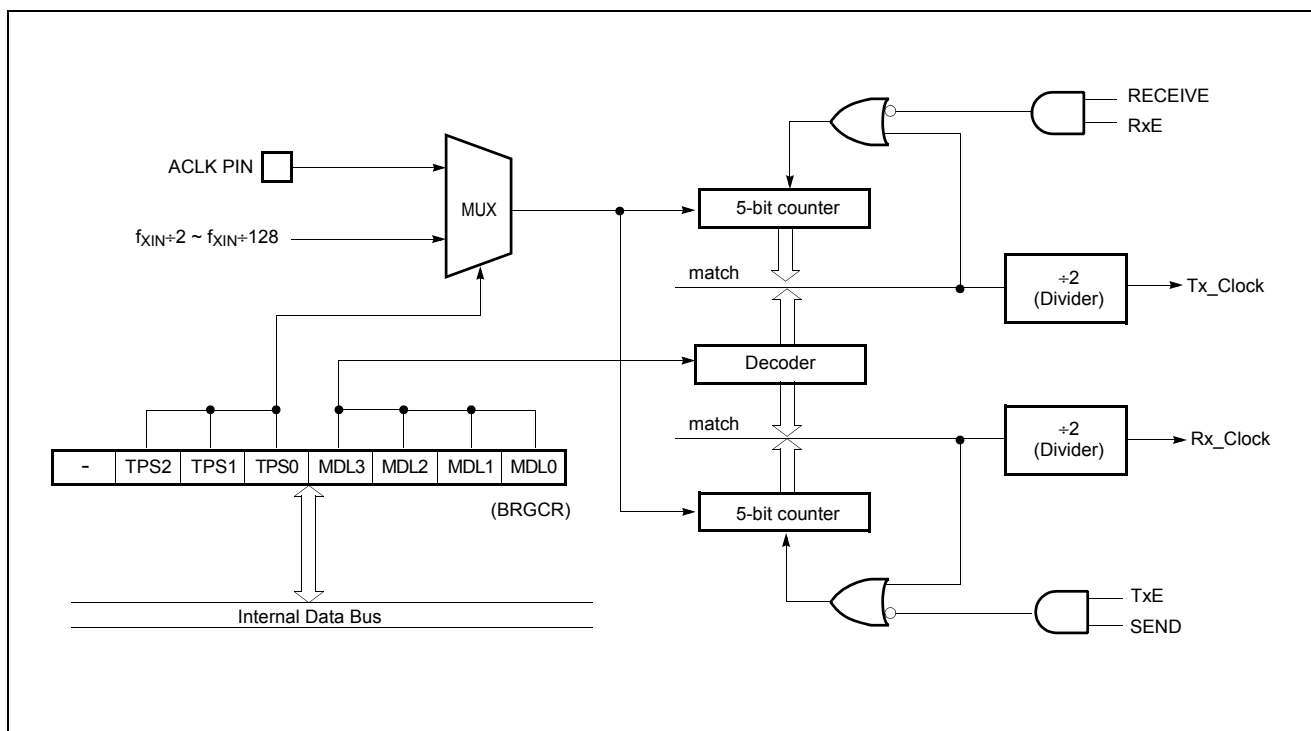

Figure 16-2 Baud Rate Generator Block Diagram

16.2 Serial Interface Configuration

The UART interface consists of the following hardware.

Item	Configuration
Register	Transmit shift register (TXR) Receive buffer register (RXR) Receive shift register
Control register	Serial interface mode register (ASIMR) Serial interface status register (ASISR) Baud rate generator control register (BRGCR)

Table 16-1 Serial Interface Configuration

Transmit shift register (TXR)

This is the register for setting transmit data. Data written to TXR is transmitted as serial data. When the data length is set as 7 bit, bit 0 to 6 of the data written to TXR are transferred as transmit data. Writing data to TXR starts the transmit operation.

TXR can be written by an 8 bit memory manipulation instruction. It cannot be read. The $\overline{\text{RESET}}$ input sets TXR to 0FF_H.

Receive buffer register (RXR)

This register is used to hold receive data. When one byte of

data is received, one byte of new receive data is transferred from the receive shift register (RXSR). When the data length is set as 7 bits, receive data is sent to bits 0 to 6 of RXR. In this case, the MSB of RXR always becomes 0. RXR can be read by an 8 bit memory manipulation instruction. It cannot be written. The $\overline{\text{RESET}}$ input sets RXR to 00_H.

Receive shift register

This register converts serial data input via the RXD pin to paralleled data. When one byte of data is received at this register cannot be manipulated directly by a program.

Asynchronous serial interface mode register (ASIMR)

This is an 8 bit register that controls UART serial transfer operation. ASIMR is set by a 1 bit or 8 bit memory manipulation instruction. The $\overline{\text{RESET}}$ input sets ASIMR to 0000_00_B. Figure 16-3 shows the format of ASIMR. The RXD / R04 and TXD / R05 pin function selection is shown in Table 16-2.

Note: Do not switch the operation mode until the current serial transmit/receive operation has stopped.

Figure 16-3 Asynchronous Serial Interface Mode register (ASIMR) Format

TXE (ASIMR.7)	RXE(ASIMR.6)	EC0(PSR0.4)	Operation Mode	RXD/R04	TXD/R05
0	0	X ¹	Operation Stop	R04	R05
0	1	0	UART mode (Receive only)	RXD	R05
1	0	X	UART mode (Transmit only)	R04	TXD
1	1	0	UART mode (Transmit and receive)	RXD	TXD

Table 16-2 UART mode and RXD/TXD pin function

1. X: The value "0" or "1" corresponding your operation

Asynchronous serial interface status register (ASISR)

When a receive error occurs during UART mode, this register indicates the type of error. ASISR can be read by an 8 bit memory manipulation instruction. The RESET input

sets ASISR to ----_000B. Figure 16-4 shows the format of ASISR.

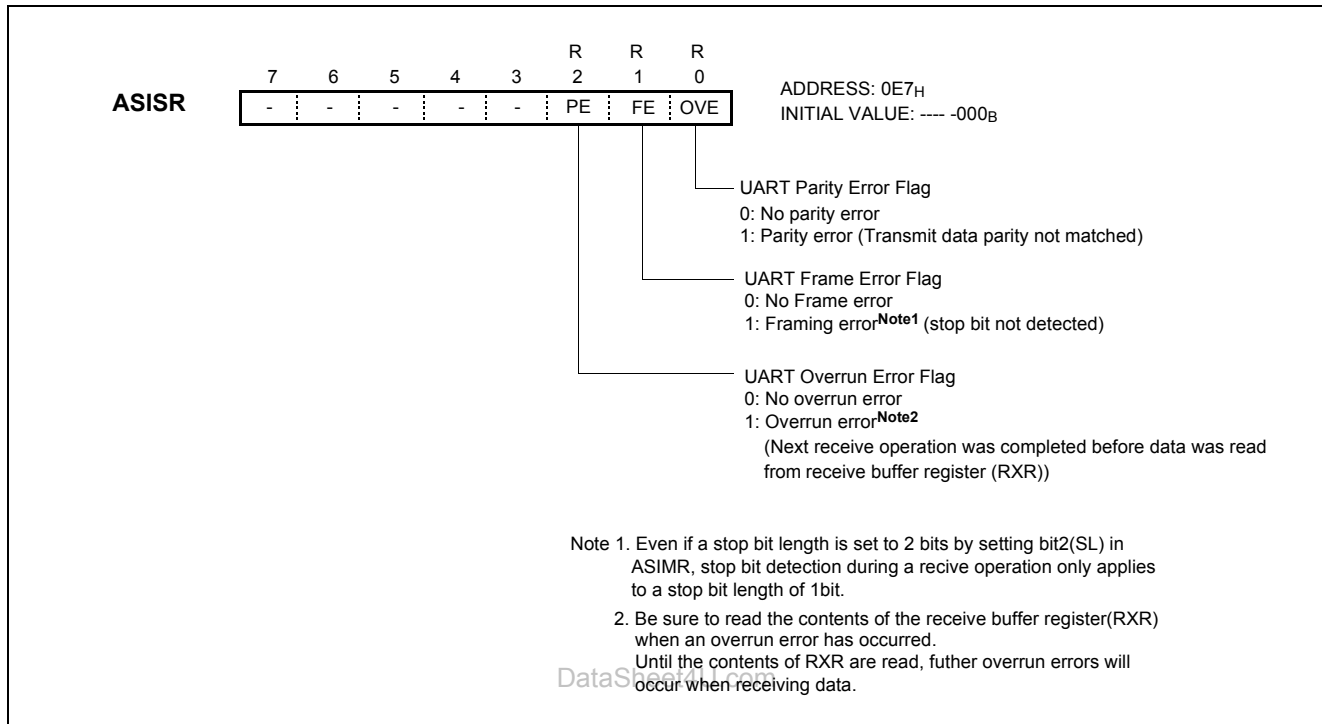

Figure 16-4 Asynchronous Serial Interface Status Register (ASISR) Format

Baud rate generator control register (BRGCR)

This register sets the serial clock for serial interface. BRGCR is set by an 8 bit memory manipulation instruction. The RESET input sets BRGCR to -001_0000B.

Figure 16-5 shows the format of BRGCR.

Figure 16-5 Baud Rate Generator Control Register (BRGCR) Format

16.3 Communication operation

The transmit operation is enabled when bit 7 (TXE) of the asynchronous serial interface mode register (ASIMR) is set to 1. The transmit operation is started when transmit data is written to the transmit shift register (TXR). The timing of the transmit completion interrupt request is shown in Figure 16-6.

The receive operation is enabled when bit 6 (RXE) of the asynchronous serial interface mode register (ASIMR) is set to 1, and input via the RxD pin is sampled. The serial clock specified by ASIMR is used to sample the RxD pin.

Once reception of one data frame is completed, a receive completion interrupt request (INT_RX) occurs. Even if an error has occurred, the receive data in which the error occurred is still transferred to RXR. When ASIMR bit 1 (ISRM) is cleared to 0 upon occurrence of an error, and INT_RX occurs. When ISRM bit is set to 1, INT_RX does not occur in case of error occurrence. Figure 16-6 shows the timing of the asynchronous serial interface receive completion interrupt request.

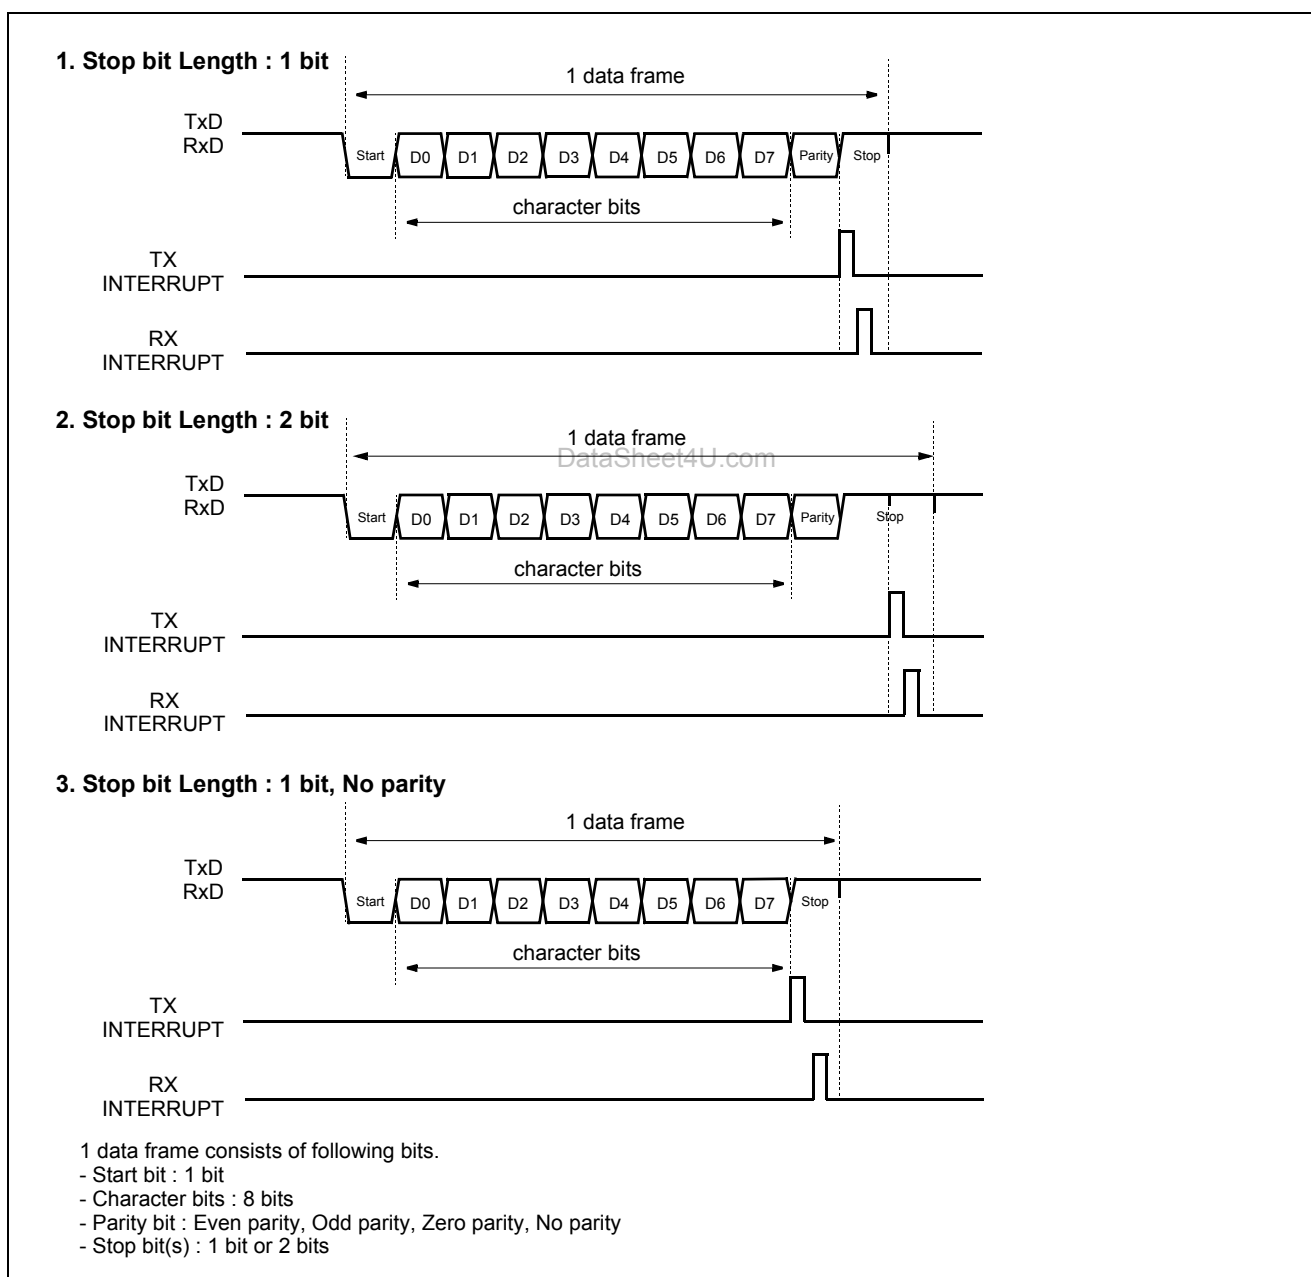

Figure 16-6 UART data format and interrupt timing diagram

16.4 Relationship between main clock and baud rate

The transmit/receive clock that is used to generate the baud rate is obtained by dividing the main system clock. Transmit/Receive clock generation for baud rate is made by us-

ing main system clock which is divided. The baud rate generated from the main system clock is determined according to the following formula.

Baud Rate (bps)	f _{XIN} =11.0592M		f _{XIN} =10.0M		f _{XIN} =8.0M		f _{XIN} =4.0M		f _{XIN} =2.0M	
	BRGCR	ERR(%)	BRGCR	ERR(%)	BRGCR	ERR(%)	BRGCR	ERR(%)	BRGCR	ERR(%)

DataSheet4U.com

Baud Rate = $f_{XIN} \div (2^{n+1}(k+16))$

Remarks 1. f_{XIN} : Main system clock oscillation frequency
 When ACLK is selected as the source clock of the 5-bit counter, substitute the input clock frequency to ACLK pin for in the above expression.

2. f_{SCK} : Source clock for 5 bit counter
 3. n : Value set via TPS0 to TPS2 (0 ≤ n ≤ 7)
 4. k : Source clock for 5 bit counter (0 ≤ k ≤ 14)

Figure 16-7 Relationship between main clock and Baud Rate

17. BUZZER FUNCTION

The buzzer driver block consists of 6-bit binary counter, buzzer register BUZR, and clock source selector. It generates square-wave which has very wide range frequency (488Hz ~ 250kHz at $f_{XIN}= 4MHz$) by user software.

A 50% duty pulse can be output to R13 / BUZO pin to use for piezo-electric buzzer drive. Pin R13 is assigned for output port of Buzzer driver by setting the bit 2 of PSR1 (address 0F9H) to "1". For PSR1 register, refer to Figure 17-2

Example: 5kHz output at 4MHz.

```
LDM BUZR, #0011_0001B
LDM PSR1, #XXXX_X1XXB
```

X means don't care

The bit 0 to 5 of BUZR determines output frequency for buzzer driving.

Equation of frequency calculation is shown below.

$$f_{BUZ} = \frac{f_{XIN}}{2 \times DivideRatio \times (BUR + 1)}$$

- f_{BUZ} : Buzzer frequency
- f_{XIN} : Oscillator frequency
- Divide Ratio: Prescaler divide ratio by BUCK[1:0]
- BUR: Lower 6-bit value of BUZR. Buzzer period value.

The frequency of output signal is controlled by the buzzer control register BUZR. The bit 0 to bit 5 of BUZR determine output frequency for buzzer driving.

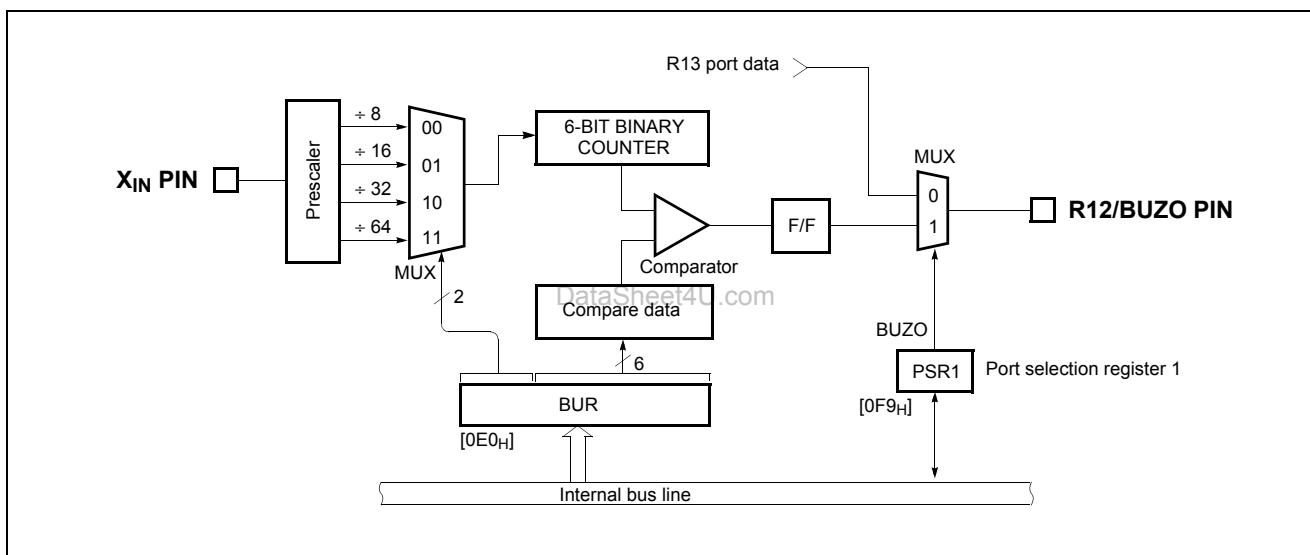

Figure 17-1 Block Diagram of Buzzer Driver

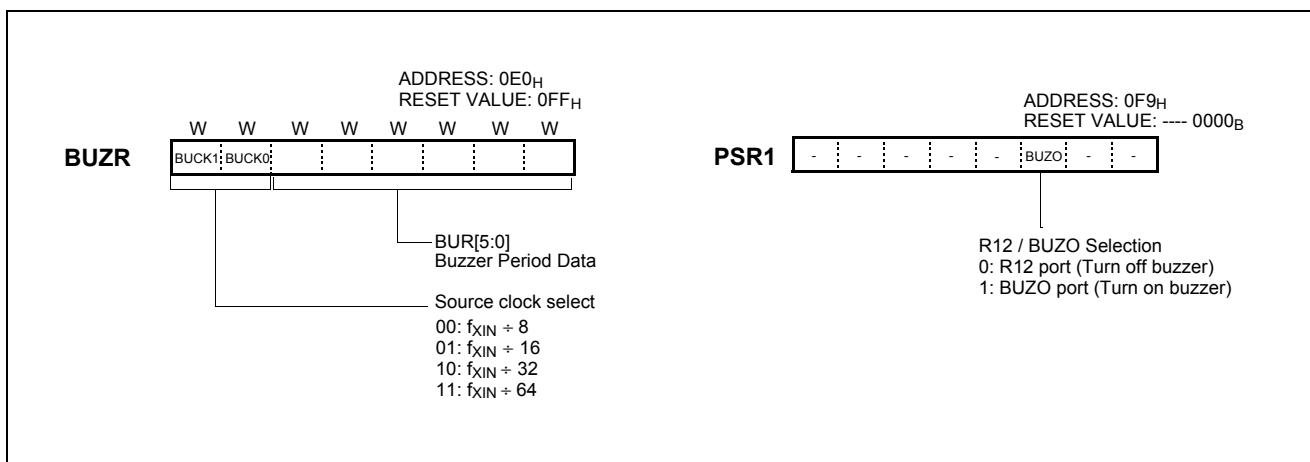

Figure 17-2 Buzzer Register & PSR1

The 6-bit counter is cleared and starts the counting by writing signal at BUZR register. It is incremental from 00_H until it matches 6-bit BUR value.

When main-frequency is 4MHz, buzzer frequency is shown as below Table 17-1.

BUR [5:0]	BUR[7:6]			
	00	01	10	11
00	250.000	125.000	62.500	31.250

Table 17-1 buzzer frequency (kHz unit)

18. INTERRUPTS

The HMS83F012/022 interrupt circuits consist of Interrupt enable register (IENH, IENL), Interrupt request flags of IRQH, IRQL, Priority circuit, and Master enable flag ("I" flag of PSW). Fifteen interrupt sources are provided. The configuration of interrupt circuit is shown in Figure 18-1 and interrupt priority is shown in Table 18-1.

The External Interrupts INT0 ~ INT3 each can be transition-activated (1-to-0 or 0-to-1 transition) by selection IEDS register.

The flags that actually generate these interrupts are bit INT0IF, INT1IF, INT2IF and INT3IF in register IRQH. When an external interrupt is generated, the generated flag is cleared by the hardware when the service routine is vec-

tored to only if the interrupt was transition-activated.

The Timer 0 ~ Timer 3 Interrupts are generated by T0IF, T1IF, T2IF and T3IF which is set by a match in their respective timer/counter register.

The Basic Interval Timer Interrupt is generated by BITIF which is set by an overflow in the timer register.

The AD converter Interrupt is generated by ADCIF which is set by finishing the analog to digital conversion.

The Watchdog timer is generated by WDTIF and WTIF which is set by a match in Watchdog timer register.

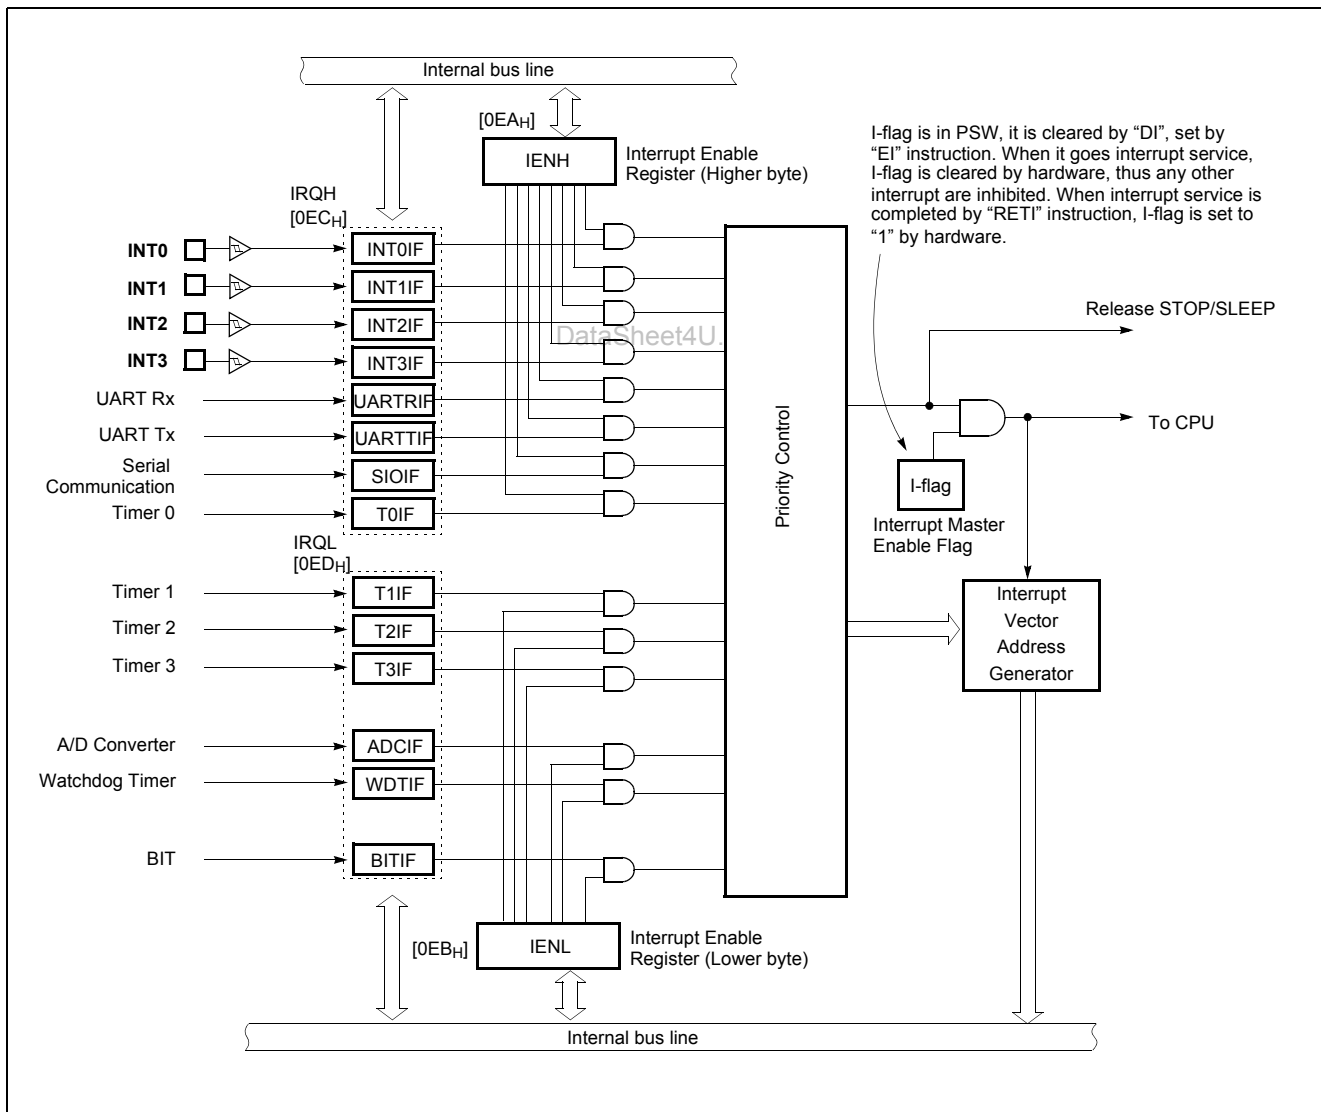

Figure 18-1 Block Diagram of Interrupt

The Basic Interval Timer Interrupt is generated by BITIF which is set by a overflow in the timer counter register.

The UART receive or transmit interrupts are generated by UARTRIF or UARTRIF are set by completion of UART data reception or transmission.

The SIO interrupt is generated by SIOIF which is set by completion of SIO data reception or transmission.

The interrupts are controlled by the interrupt master enable flag I-flag (bit 2 of PSW on Figure 8-3), the interrupt enable register (IENH, IENL), and the interrupt request flags (in IRQH and IRQL) except Power-on reset and software BRK interrupt. The Table 18-1 shows the Interrupt priority.

Vector addresses are shown in Figure 8-6 . Interrupt enable registers are shown in Figure 18-2 . These registers are composed of interrupt enable flags of each interrupt source and these flags determines whether an interrupt will be accepted or not. When enable flag is "0", a corresponding interrupt source is prohibited. Note that PSW contains also a master enable bit, I-flag, which disables all interrupts at once.

Reset/Interrupt	Symbol	Priority
Hardware Reset	RESET	1
External Interrupt 0	INT0	2
External Interrupt 1	INT1	3
External Interrupt 2	INT2	4
External Interrupt 3	INT3	5
UART Rx Interrupt	INT_RX	6
UART Tx Interrupt	INT_TX	7
Serial Input/Output	SIO	8
Timer/Counter 0	Timer 0	9
Timer/Counter 1	Timer 1	10
Timer/Counter 2	Timer 2	11
Timer/Counter 3	Timer 3	12
ADC Interrupt	ADC	13
Watchdog Timer	WDT	14
Basic Interval Timer	BIT	15

Table 18-1 Interrupt Priority

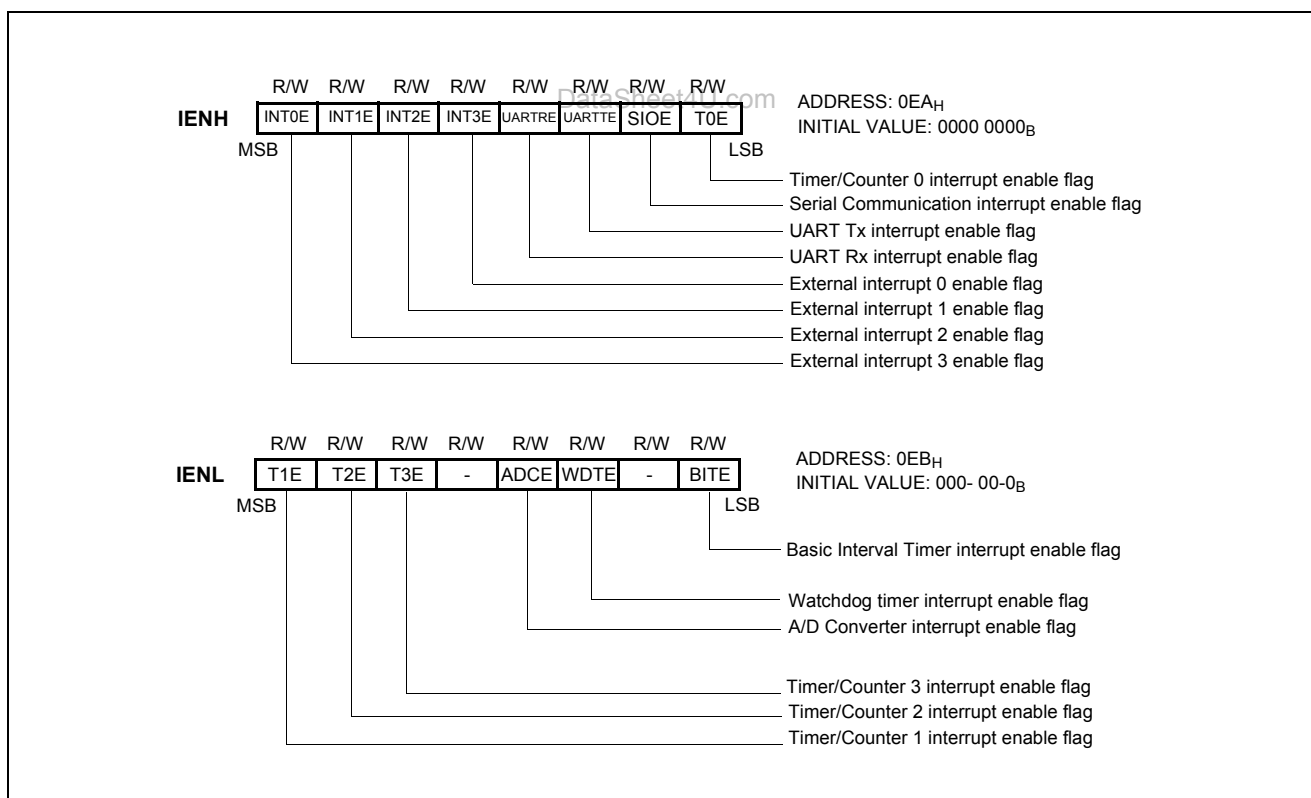

Figure 18-2 Interrupt Enable Flag Register

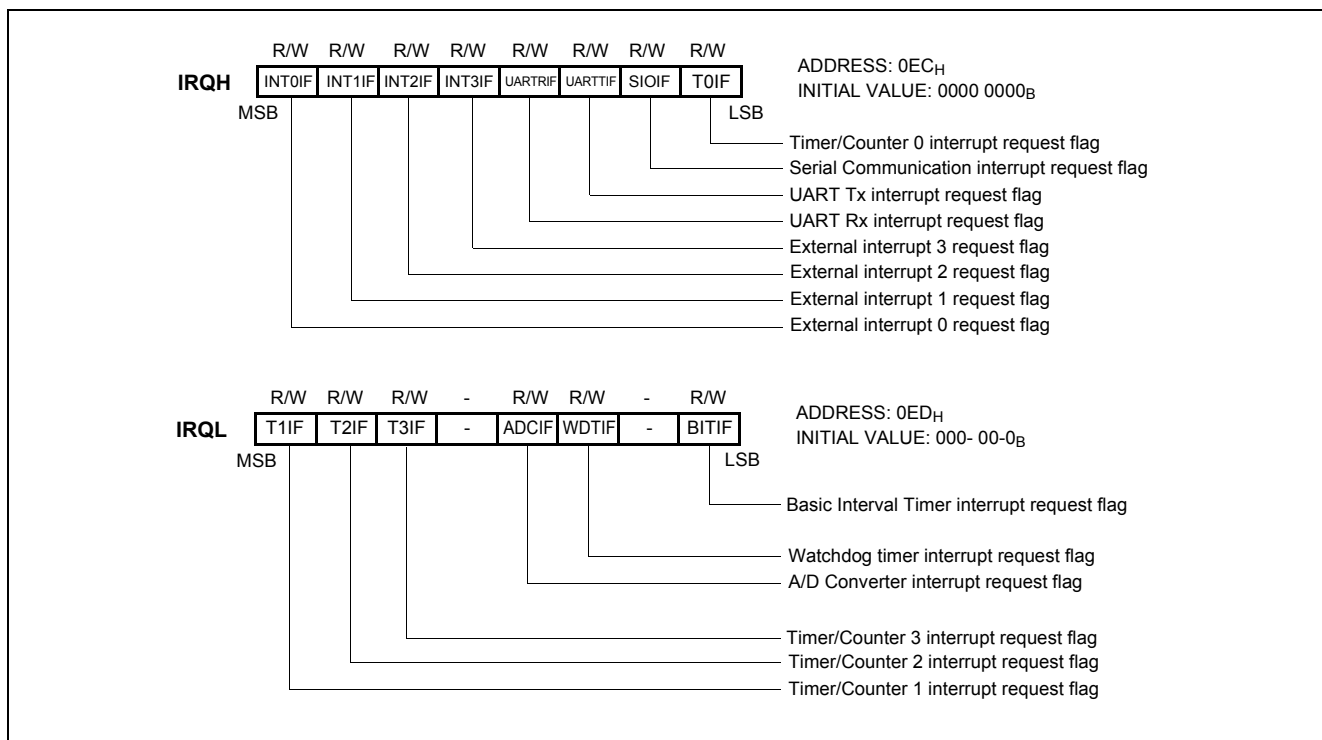

Figure 18-3 Interrupt Request Flag Register

18.1 Interrupt Sequence

An interrupt request is held until the interrupt is accepted or the interrupt latch is cleared to “0” by a reset or an instruction. Interrupt acceptance sequence requires 8 cycles of f_{XIN} ($2\mu s$ at $f_{XIN}=4MHz$) after the completion of the

current instruction execution. The interrupt service task is terminated upon execution of an interrupt return instruction [RETI].

18.1.1 Interrupt acceptance

1. The interrupt master enable flag (I-flag) is cleared to “0” to temporarily disable the acceptance of any following maskable interrupts. When a non-maskable interrupt is accepted, the acceptance of any following interrupts is temporarily disabled.
2. Interrupt request flag for the interrupt source accepted is cleared to “0”.
3. The contents of the program counter (return address)

and the program status word are saved (pushed) onto the stack area. The stack pointer decreases 3 times.

4. The entry address of the interrupt service program is read from the vector table address and the entry address is loaded to the program counter.
5. The instruction stored at the entry address of the interrupt service program is executed.

Figure 18-4 Timing chart of Interrupt Acceptance and Interrupt Return Instruction

Correspondence between vector table address for BIT interrupt and the entry address of the interrupt service program.

18.1.2 Saving/Restoring General-purpose Register

During interrupt acceptance processing, the program counter and the program status word are automatically saved on the stack, but accumulator and other registers are not saved itself. These registers are saved by the software if necessary. Also, when multiple interrupt services are nested, it is necessary to avoid using the same data memory area for saving registers.

The following method is used to save/restore the general-purpose registers.

Example: Register save using push and pop instruc-

tions

```
INTxx:  PUSH   A      ;SAVE ACC.
        PUSH   X      ;SAVE X REG.
        PUSH   Y      ;SAVE Y REG.
```

interrupt processing

```
POP     Y      ;RESTORE Y REG.
POP     X      ;RESTORE X REG.
POP     A      ;RESTORE ACC.
RETI                    ;RETURN
```

General-purpose register save/restore using push and pop instructions;

18.2 BRK Interrupt

Software interrupt can be invoked by BRK instruction, which has the lowest priority order.

Interrupt vector address of BRK is shared with the vector of TCALL 0 (Refer to Program Memory Section). When BRK interrupt is generated, B-flag of PSW is set to distinguish BRK from TCALL 0.

Each processing step is determined by B-flag as shown in Figure 18-5 .

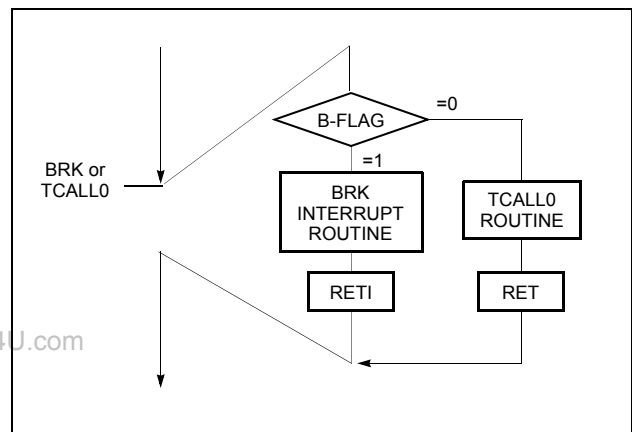

Figure 18-5 Execution of BRK/TCALL0

18.3 Multi Interrupt

If two requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If requests of the interrupt are received at the same time simultaneously, an internal polling sequence determines by hardware which request is serviced. However,

multiple processing through software for special features is possible. Generally when an interrupt is accepted, the I-flag is cleared to disable any further interrupt. But as user sets I-flag in interrupt routine, some further interrupt can

18.4 External Interrupt

The external interrupt on INT0, INT1, INT2 and INT3 pins are edge triggered depending on the edge selection register IEDS (address 0EEH) as shown in Figure 18-7.

The edge detection of external interrupt has three transition activated mode: rising edge, falling edge, and both edge.

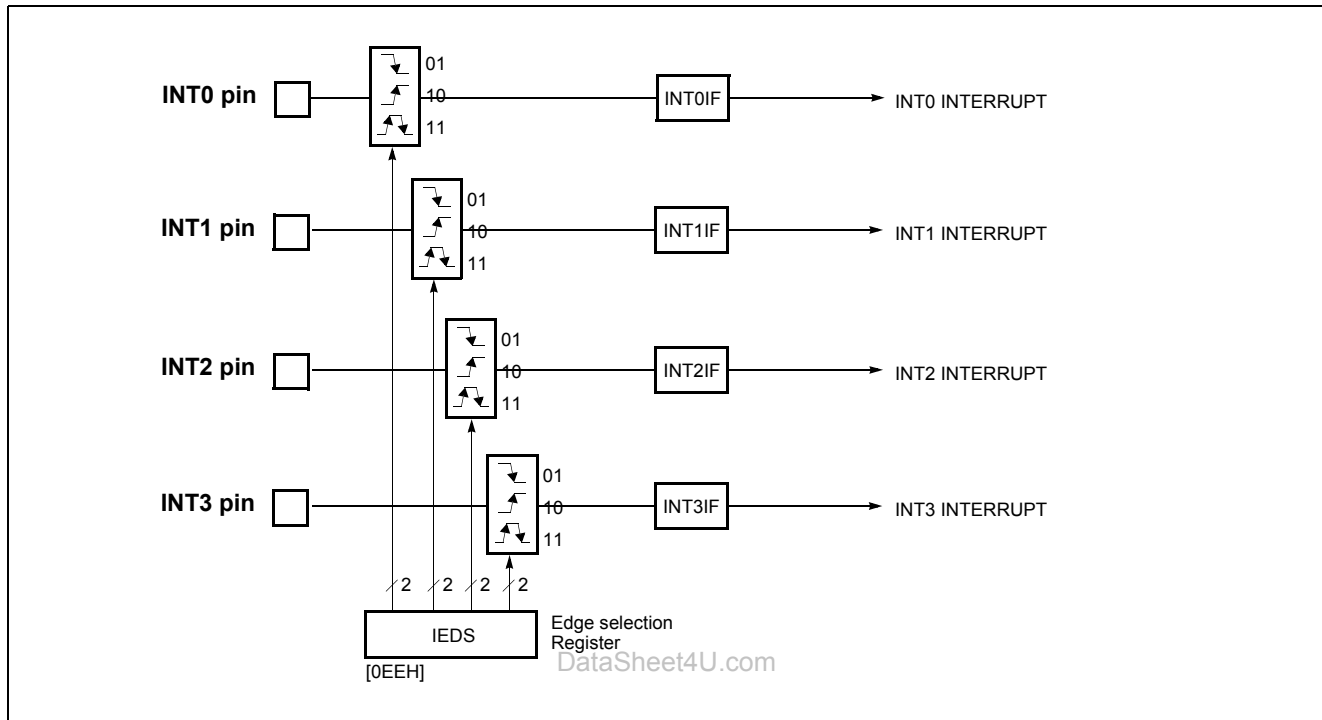

Figure 18-7 External Interrupt Block Diagram

INT0 ~ INT3 are multiplexed with general I/O ports (R11, R12, R03, R00). To use as an external interrupt pin, the bit of port selection register PSR0 should be set to "1" correspondingly.

Example: To use as an INT0 and INT2

```

:
;**** Set external interrupt port as pull-up state.
LDM  PU1, #0000_0101B
;
;**** Set port as an external interrupt port
LDM  PSR0, #0000_0101B
;
;**** Set Falling-edge Detection
LDM  IEDS, #0001_0001B
:

```

Response Time

The INT0 ~ INT3 edge are latched into INT0IF ~ INT3IF at every machine cycle. The values are not actually polled by the circuitry until the next machine cycle. If a request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The DIV itself takes twelve cycles. Thus, a minimum of twelve complete machine cycles elapse between activation of an external interrupt request and the beginning of execution of the first instruction of the service routine.

Figure 18-8 shows interrupt response timings.

Figure 18-8 Interrupt Response Timing Diagram

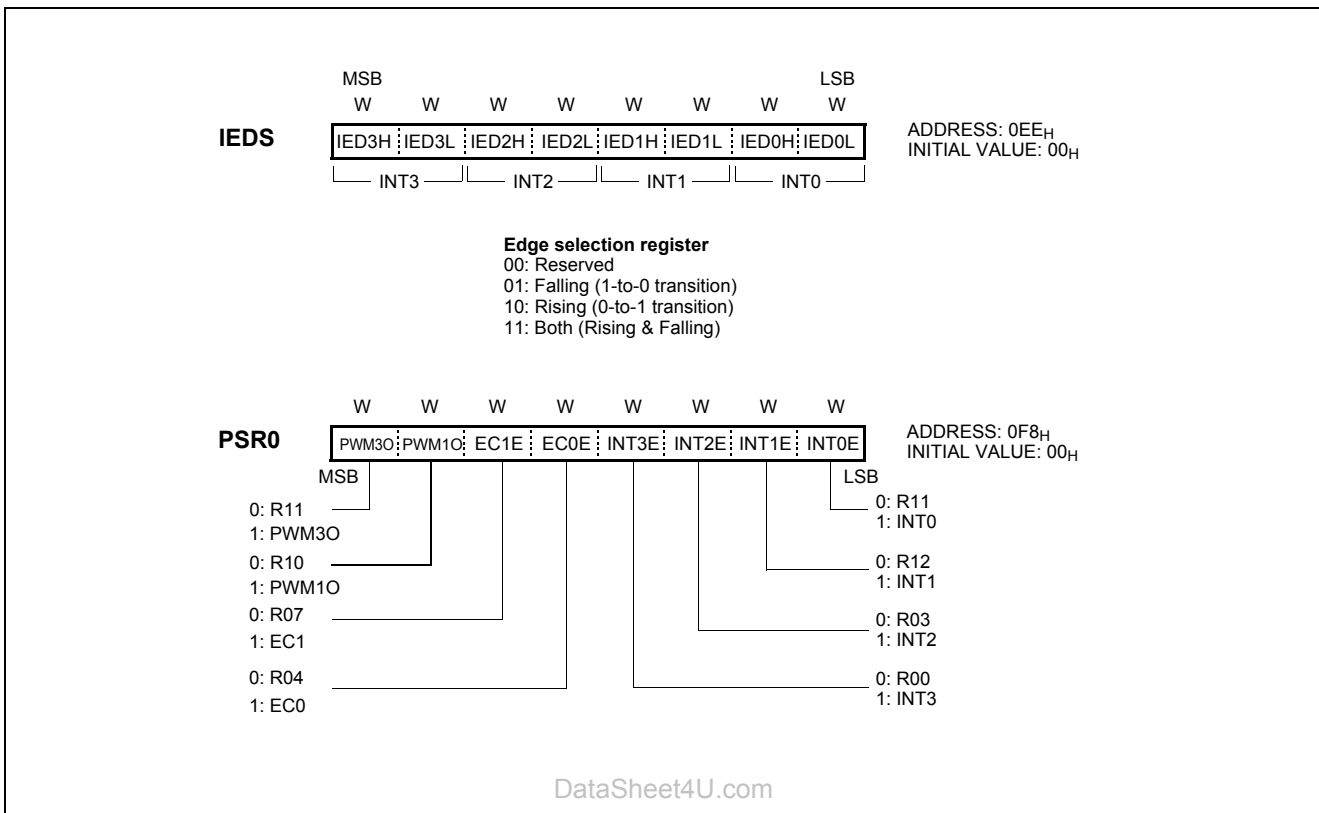

Figure 18-9 IEDS register and Port Selection Register PSR0

19. POWER SAVING OPERATION

TheHMS83F012/022 has two power-down modes. In power-down mode, power consumption is reduced considerably. For applications where power consumption is a critical factor, device provides two kinds of power saving functions, STOP mode and SLEEP mode. Table 19-1

shows the status of each Power Saving Mode. SLEEP mode is entered by the SSCR register to “0Fh”, and STOP mode is entered by STOP instruction after the SSCR register to “5Ah”.

19.1 Sleep Mode

In this mode, the internal oscillation circuits remain active. Oscillation continues and peripherals are operate normally but CPU stops. Movement of all peripherals is shown in Table 19-1. SLEEP mode is entered by setting the SSCR register to “0Fh”. It is released by Reset or interrupt. To be

released by interrupt, interrupt should be enabled before SLEEP mode.

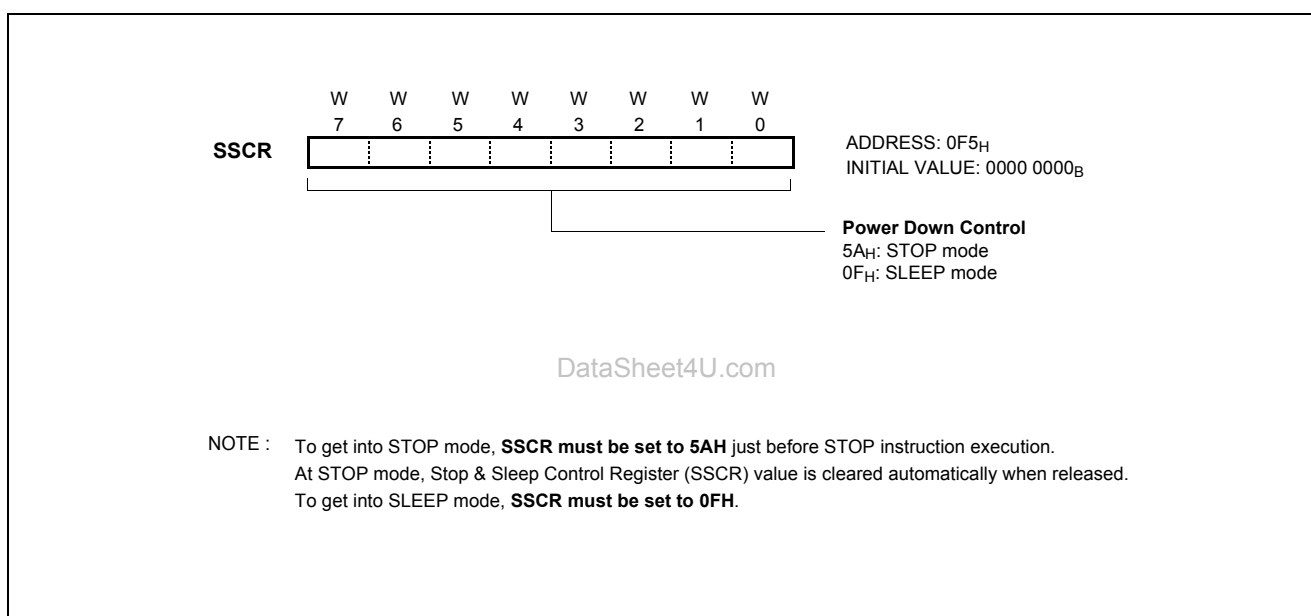

Figure 19-1 STOP and SLEEP Control Register

Release the SLEEP mode

The exit from SLEEP mode is hardware reset or all interrupts. Reset re-defines all the Control registers but does not change the on-chip RAM. Interrupts allow both on-chip RAM and Control registers to retain their values.

If I-flag = 1, the normal interrupt response takes place. If I-flag = 0, the chip will resume execution starting with the instruction following the SLEEP instruction. It will not vector to interrupt service routine. (refer to Figure 19-4)

When exit from SLEEP mode by reset, enough oscillation

stabilizing time is required to normal operation. Figure 19-3 shows the timing diagram. When released from the SLEEP mode, the Basic interval timer is activated on wake-up. It is increased from 00_H until FF_H. The count overflow is set to start normal operation. Therefore, before SLEEP instruction, user must be set its relevant prescaler divide ratio to have long enough time (more than 20msec). This guarantees that oscillator has started and stabilized. By interrupts, exit from SLEEP mode is shown in Figure 19-2 . By reset, exit from SLEEP mode is shown in Figure 19-3 .

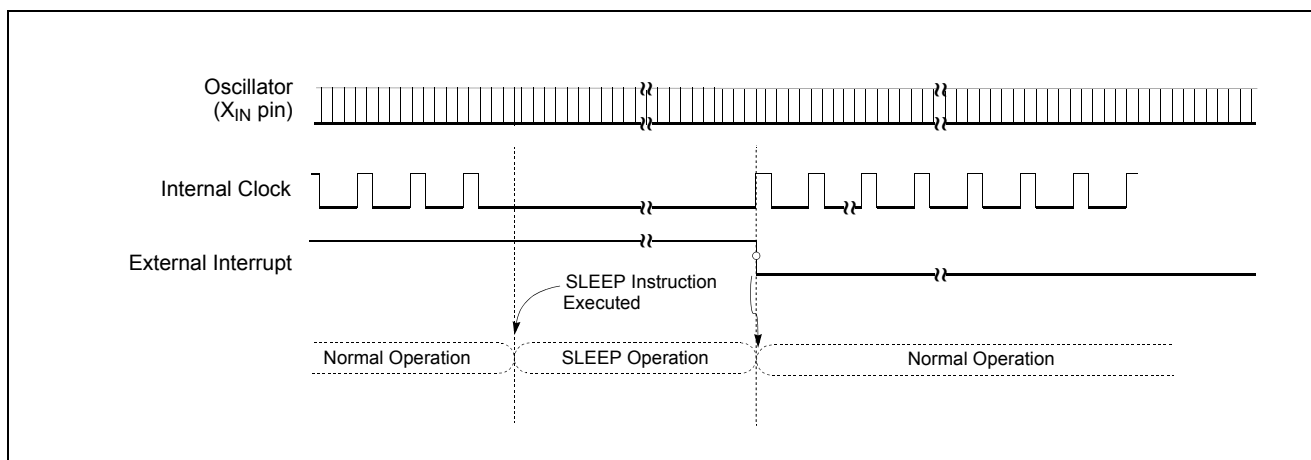

Figure 19-2 SLEEP Mode Release Timing by External Interrupt

Figure 19-3 Timing of SLEEP Mode Release by Reset

19.2 Stop Mode

In the Stop mode, the main oscillator, system clock and peripheral clock is stopped, but RC-oscillated watchdog timer continue to operate. With the clock frozen, all functions are stopped, but the on-chip RAM and Control registers are held. The port pins out the values held by their respective port data register, port direction registers. Oscillator stops and the systems internal operations are all held up.

- The states of the RAM, registers, and latches valid immediately before the system is put in the STOP state are all held.
- The program counter stop the address of the instruction to be executed after the instruction

"STOP" which starts the STOP operating mode.

Note: The Stop mode is activated by execution of STOP instruction after setting the SSCR to "5AH". (This register should be written by byte operation. If this register is set by bit manipulation instruction, for example "set1" or "clr1" instruction, it may be undesired operation)

In the Stop mode of operation, V_{DD} can be reduced to minimize power consumption. Care must be taken, however, to ensure that V_{DD} is not reduced before the Stop mode is invoked, and that V_{DD} is restored to its normal operating level, before the Stop mode is terminated.

The reset should not be activated before V_{DD} is restored to its normal operating level, and must be held active long enough to allow the oscillator to restart and stabilize.

Note: After STOP instruction, at least two or more NOP instruction should be written.

Ex) LDM CKCTRL,#0FH ;more than 20ms
LDM SSCR,#5AH
STOP
NOP ;for stabilization time
NOP ;for stabilization time

In the STOP operation, the dissipation of the power associated with the oscillator and the internal hardware is lowered; however, the power dissipation associated with the

pin interface (depending on the external circuitry and program) is not directly determined by the hardware operation of the STOP feature. This point should be little current flows when the input level is stable at the power voltage level (V_{DD}/V_{SS}); however, when the input level gets higher than the power voltage level (by approximately 0.3 to 0.5V), a current begins to flow. Therefore, if cutting off the output transistor at an I/O port puts the pin signal into the high-impedance state, a current flow across the ports input transistor, requiring to fix the level by pull-up or other means.

Peripheral	STOP Mode	SLEEP Mode
CPU	Stop	Stop
RAM	Retain	Retain
Basic Interval Timer	Halted	Operates Continuously
Watchdog Timer	Stop (Only operates in RC-WDT mode)	Stop
Timer/Counter	Halted (Only when the event counter mode is enabled, timer operates normally)	Operates Continuously
Buzzer, ADC	Stop	Stop
SIO	Only operate with external clock	Only operate with external clock
UART	Only operate with external clock	Only operate with external clock
Oscillator	Stop ($X_{IN}=L, X_{OUT}=H$)	Oscillation
I/O Ports	Retain	Retain
Control Registers	Retain	Retain
Internal Circuit	Stop mode	Sleep mode
Prescaler	Retain	Active
Address Data Bus	Retain	Retain
Release Source	Reset, Timer(EC0,1), SIO, UART(using ACLK), Watchdog Timer (RC-WDT mode), External Interrupt	Reset, All Interrupts

Table 19-1 Peripheral Operation During Power Saving Mode

Release the STOP mode

The source for exit from STOP mode is hardware reset, external interrupt, Timer(EC0,1), Watch Timer, WDT, SIO or UART. Reset re-defines all the Control registers but does not change the on-chip RAM. External interrupts allow both on-chip RAM and Control registers to retain their values.

If I-flag = 1, the normal interrupt response takes place. If I-flag = 0, the chip will resume execution starting with the instruction following the STOP instruction. It will not vec-

tor to interrupt service routine. (refer to Figure 19-4)

When exit from Stop mode by external interrupt, enough oscillation stabilizing time is required to normal operation. Figure 19-5 shows the timing diagram. When released from the Stop mode, the Basic interval timer is activated on wake-up. It is increased from 00H until FFH. The count overflow is set to start normal operation. Therefore, before STOP instruction, user must be set its relevant prescaler divide ratio to have long enough time (more than 20msec). This guarantees that oscillator has started and stabilized.

By reset, exit from Stop mode is shown in Figure 19-6 .

Figure 19-4 STOP Releasing Flow by Interrupts

Figure 19-5 STOP Mode Release Timing by External Interrupt

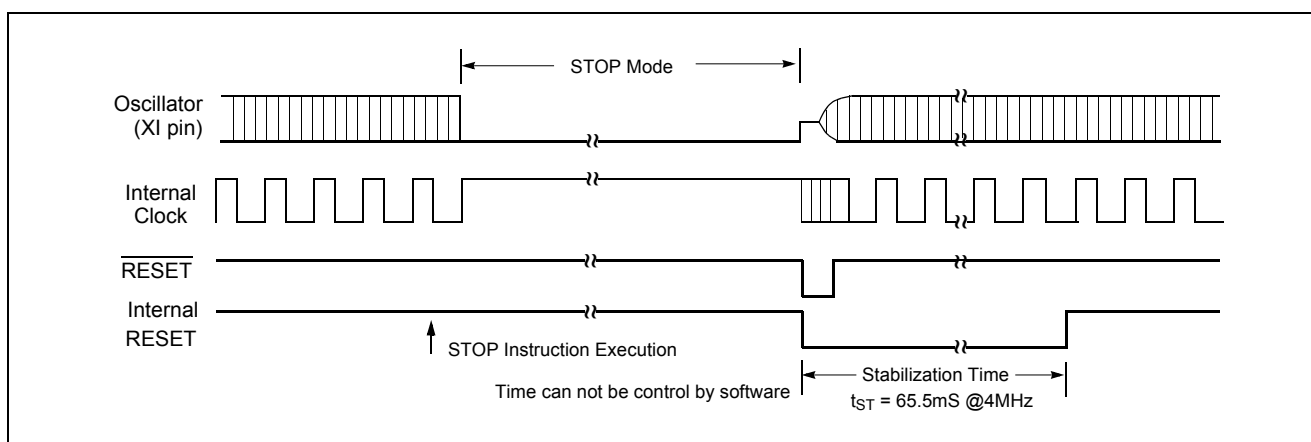

Figure 19-6 Timing of STOP Mode Release by Reset

19.3 Stop Mode at Internal RC-Oscillated Watchdog Timer Mode

In the Internal RC-Oscillated Watchdog Timer mode, the on-chip oscillator is stopped. But internal RC oscillation circuit is oscillated in this mode. The on-chip RAM and Control registers are held. The port pins out the values held by their respective port data register, port direction registers.

The Internal RC-Oscillated Watchdog Timer mode is activated by execution of STOP instruction after setting the bit RCWDT of CKCTLR to "1". (This register should be written by byte operation. If this register is set by bit manipulation instruction, for example "set1" or "clr1" instruction, it may be undesired operation)

Note: Caution: After STOP instruction, at least two or more NOP instruction should be written

```
Ex)  LDM  WDTR,#1111_1111B
      LDM  CKCTLR,#0010_1110B
      LDM  SSCR,#0101_1010B
      STOP
      NOP   ;for stabilization time
      NOP   ;for stabilization time
```

The exit from Internal RC-Oscillated Watchdog Timer mode is hardware reset or external interrupt or watchdog timer interrupt (at RC-watchdog timer mode). Reset re-de-

fines all the Control registers but does not change the on-chip RAM. External interrupts allow both on-chip RAM and Control registers to retain their values.

If I-flag = 1, the normal interrupt response takes place. In this case, if the bit WDTON of CKCTLR is set to "0" and the bit WDTE of IENH is set to "1", the device will execute the watchdog timer interrupt service routine (Figure 8-6). However, if the bit WDTON of CKCTLR is set to "1", the device will generate the internal Reset signal and execute the reset processing (Figure 19-8). If I-flag = 0, the chip will resume execution starting with the instruction following the STOP instruction. It will not vector to interrupt service routine. (refer to Figure 19-4)

When exit from Stop mode at Internal RC-Oscillated Watchdog Timer mode by external interrupt, the oscillation stabilization time is required to normal operation. Figure 19-7 shows the timing diagram. When release the Internal RC-Oscillated Watchdog Timer mode, the basic interval timer is activated on wake-up. It is increased from 00_H until FF_H. The count overflow is set to start normal operation. Therefore, before STOP instruction, user must be set its relevant prescaler divide ratio to have long enough time (more than 20msec). This guarantees that oscillator has started and stabilized. By reset, exit from internal RC-Oscillated Watchdog Timer mode is shown in Figure 19-8

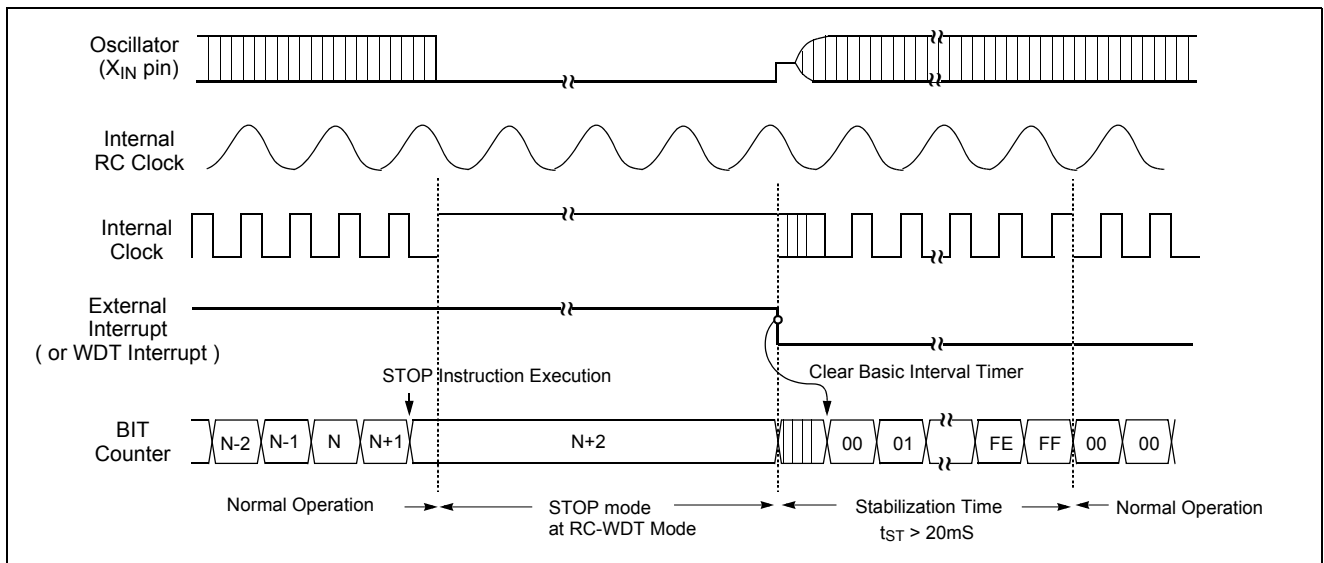

Figure 19-7 Stop Mode Release at Internal RC-WDT Mode by External Interrupt or WDT Interrupt

Figure 19-8 Internal RC-WDT Mode Releasing by Reset

19.4 Minimizing Current Consumption

The Stop mode is designed to reduce power consumption. To minimize current drawn during Stop mode, the user

should turn-off output drivers that are sourcing or sinking current, if it is practical.

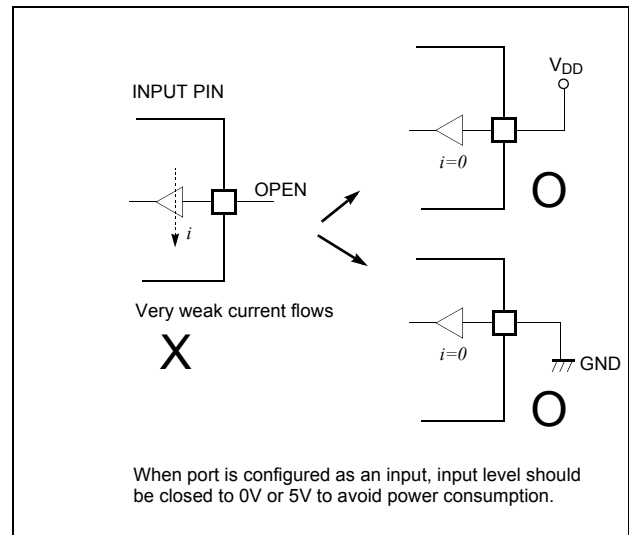

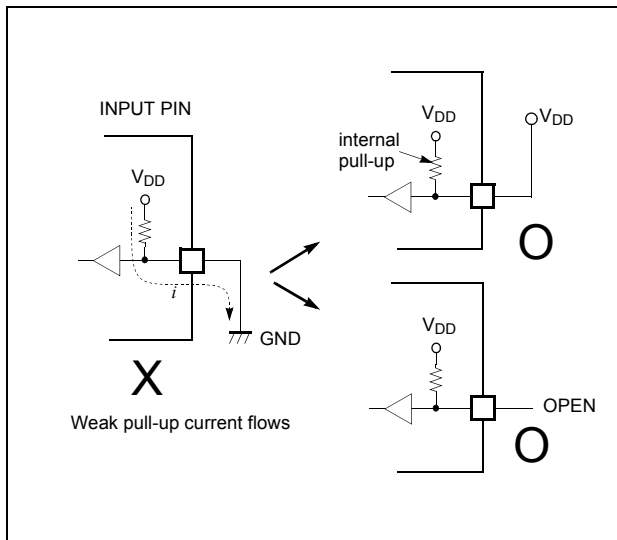

Figure 19-9 Application Example of Unused Input Port

Figure 19-10 Application Example of Unused Output Port

Note: In the STOP operation, the power dissipation associated with the oscillator and the internal hardware is lowered; however, the power dissipation associated with the pin interface (depending on the external circuitry and program) is not directly determined by the hardware operation of the STOP feature. This point should be little current flows when the input level is stable at the power voltage level (V_{DD}/V_{SS}); however, when the input level becomes higher than the power voltage level (by approximately 0.3V), a current begins to flow. Therefore, if cutting off the output transistor at an //

O port puts the pin signal into the high-impedance state, a current flow across the ports input transistor, requiring it to fix the level by pull-up or other means.

It should be set properly in order that current flow through port doesn't exist.

First consider the port setting to input mode. Be sure that there is no current flow after considering its relationship with external circuit. In input mode, the pin impedance

viewing from external MCU is very high that the current doesn't flow.

But input voltage level should be V_{SS} or V_{DD} . Be careful that if unspecified voltage, i.e. if uncertain voltage level (not V_{SS} or V_{DD}) is applied to input pin, there can be little current (max. 1mA at around 2V) flow.

If it is not appropriate to set as an input mode, then set to

output mode considering there is no current flow. The port setting to High or Low is decided by considering its relationship with external circuit. For example, if there is external pull-up resistor then it is set to output mode, i.e. to High, and if there is external pull-down register, it is set to low.

20. RESET

The HMS83F012/022 supports various kinds of reset as below.

- Power-On Reset (POR)
- $\overline{\text{RESET}}$ (external reset circuitry)
- Watchdog Timer Timeout Reset
- Power-Fail Detection (PFD) Reset
- Address Fail Reset

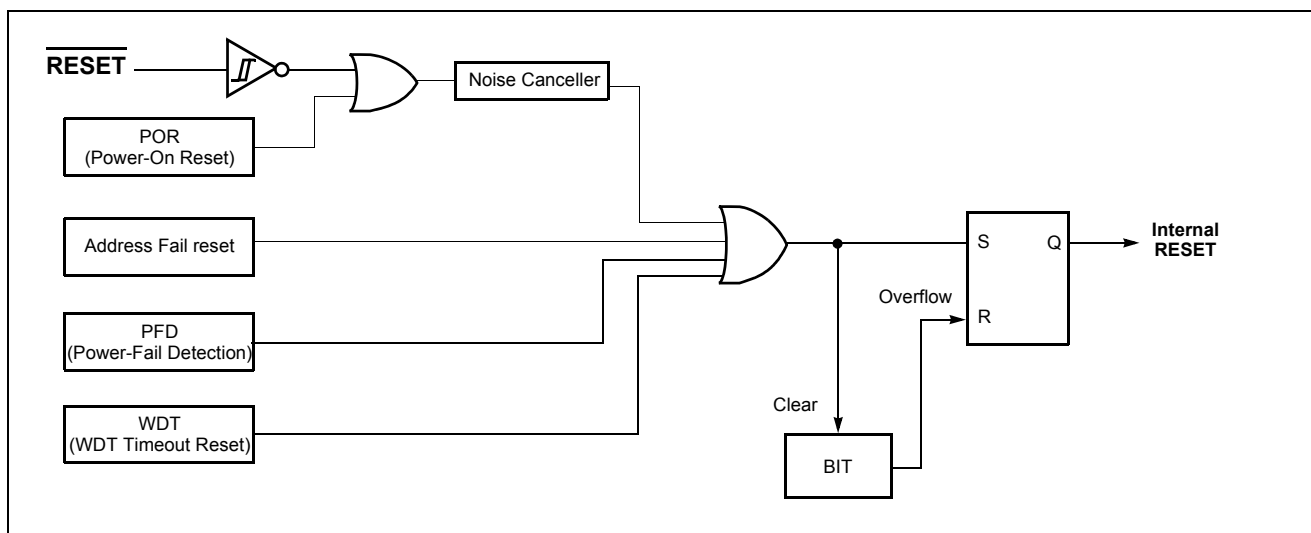

Figure 20-1 RESET Block Diagram

The on-chip POR circuit holds down the device in $\overline{\text{RESET}}$ until V_{DD} has reached a high enough level for proper operation. It will eliminate external components such as reset IC or external resistor and capacitor for external reset circuit. In addition that the $\overline{\text{RESET}}$ pin can be used to normal input port R35 by setting "POR" and "R35EN" bit Config-

uration Area(20FFH) in the Flash programming. When the device starts normal operation, its operating parameters (voltage, frequency, temperature...etc) must be met.

Table 20-1 shows on-chip hardware initialization by reset action.

On-chip Hardware	Initial Value
Program counter (PC)	(FFFF _H) - (FFFE _H)
RAM page register (RPR)	0
G-flag (G)	0
Operation mode	Main-frequency clock

On-chip Hardware	Initial Value
Peripheral clock	Off
Watchdog timer	Disable
Control registers	Refer to Table 8-1 on page 22
Power fail detector	Disable

Table 20-1 Initializing Internal Status by Reset Action

The reset input is the $\overline{\text{RESET}}$ pin, which is the input to a Schmitt Trigger. A reset is accomplished by holding the $\overline{\text{RESET}}$ pin low for at least 8 oscillator periods, within the operating voltage range and oscillation stable, it is applied, and the internal state is initialized. After reset, 65.5ms (at 4 MHz) add with 7 oscillator periods are required to start execution as shown in Figure 20-2 .

Internal RAM is not affected by reset. When V_{DD} is turned

on, the RAM content is indeterminate. Therefore, this RAM should be initialized before read or tested it.

When the $\overline{\text{RESET}}$ pin input goes to high, the reset operation is released and the program execution starts at the vector address stored at addresses FFFE_H - FFFF_H.

A connection for simple power-on-reset is shown in Figure 20-1 .

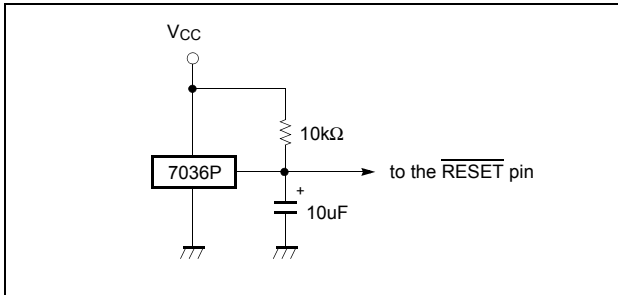

Figure 20-1 Simple Power-on-Reset Circuit

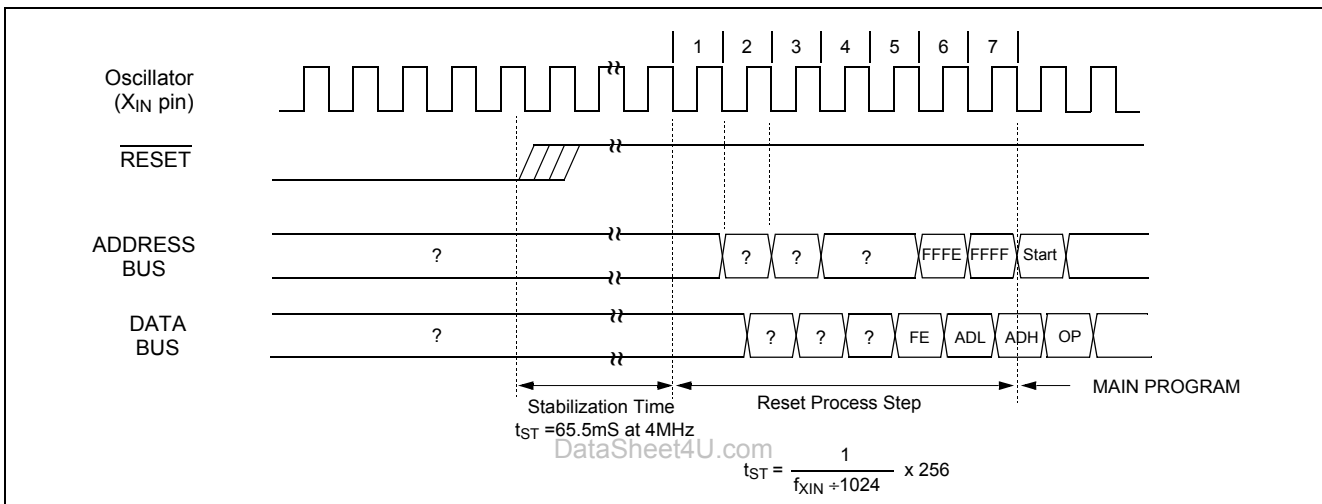

Figure 20-2 Timing Diagram after Reset

The Address Fail Reset is the function to reset the system by checking code access of abnormal and unwished address caused by erroneous program code itself or external noise, which could not be returned to normal operation and would become malfunction state. If the CPU tries to fetch

the instruction from ineffective code area or RAM area, the address fail reset is occurred. Please refer to Figure 11-2 for setting address fail option.

21. POWER FAIL PROCESSOR

TheHMS83F012/022 has an on-chip power fail detection circuitry to immunize against power noise. A configuration register, PFDR, can enable or disable the power fail detect circuitry. Whenever V_{DD} falls close to or below power fail voltage for 100ns, the power fail situation may reset or freeze MCU according to PFDM bit of PFDR. Refer to “Figure 21-1 Power Fail Voltage Detector Register”

on page 96.

In the in-circuit emulator, power fail function is not implemented and user can not experiment with it. Therefore, after final development of user program, this function may be experimented or evaluated.

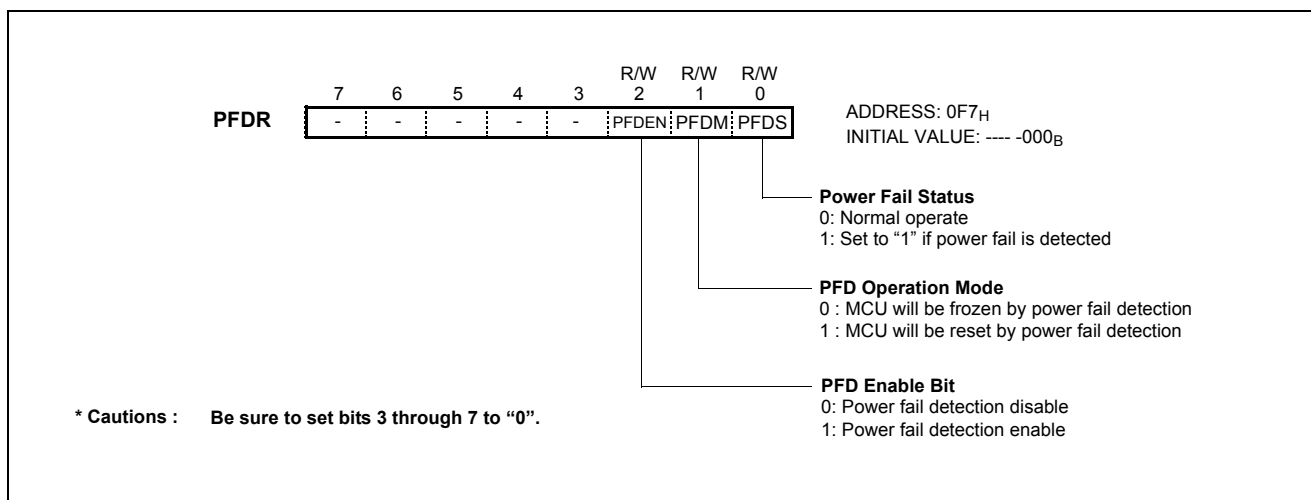

Figure 21-1 Power Fail Voltage Detector Register

Figure 21-2 Example S/W of Reset flow by Power fail

Figure 21-3 Power Fail Processor Situations (at 4MHz operation)

22. COUNTERMEASURE OF NOISE

22.1 Oscillation Noise Protector

The Oscillation Noise Protector (ONP) is used to supply stable internal system clock by excluding the noise which could be entered into oscillator and recovery the oscillation fail. This function could be enabled or disabled by the "ONP" bit of the Device configuration area (20FF_H) for the HMS83F022, "ONP" option bits MASK option.

The ONP function is like below.

- Recovery the oscillation wave crushed or loss caused

by high frequency noise.

- Change system clock to the internal oscillation clock when the high frequency noise is continuing.
- Change system clock to the internal oscillation clock when the X_{IN}/X_{OUT} is shorted or opened, the main oscillation is stopped except by stop instruction and the low frequency noise is entered.

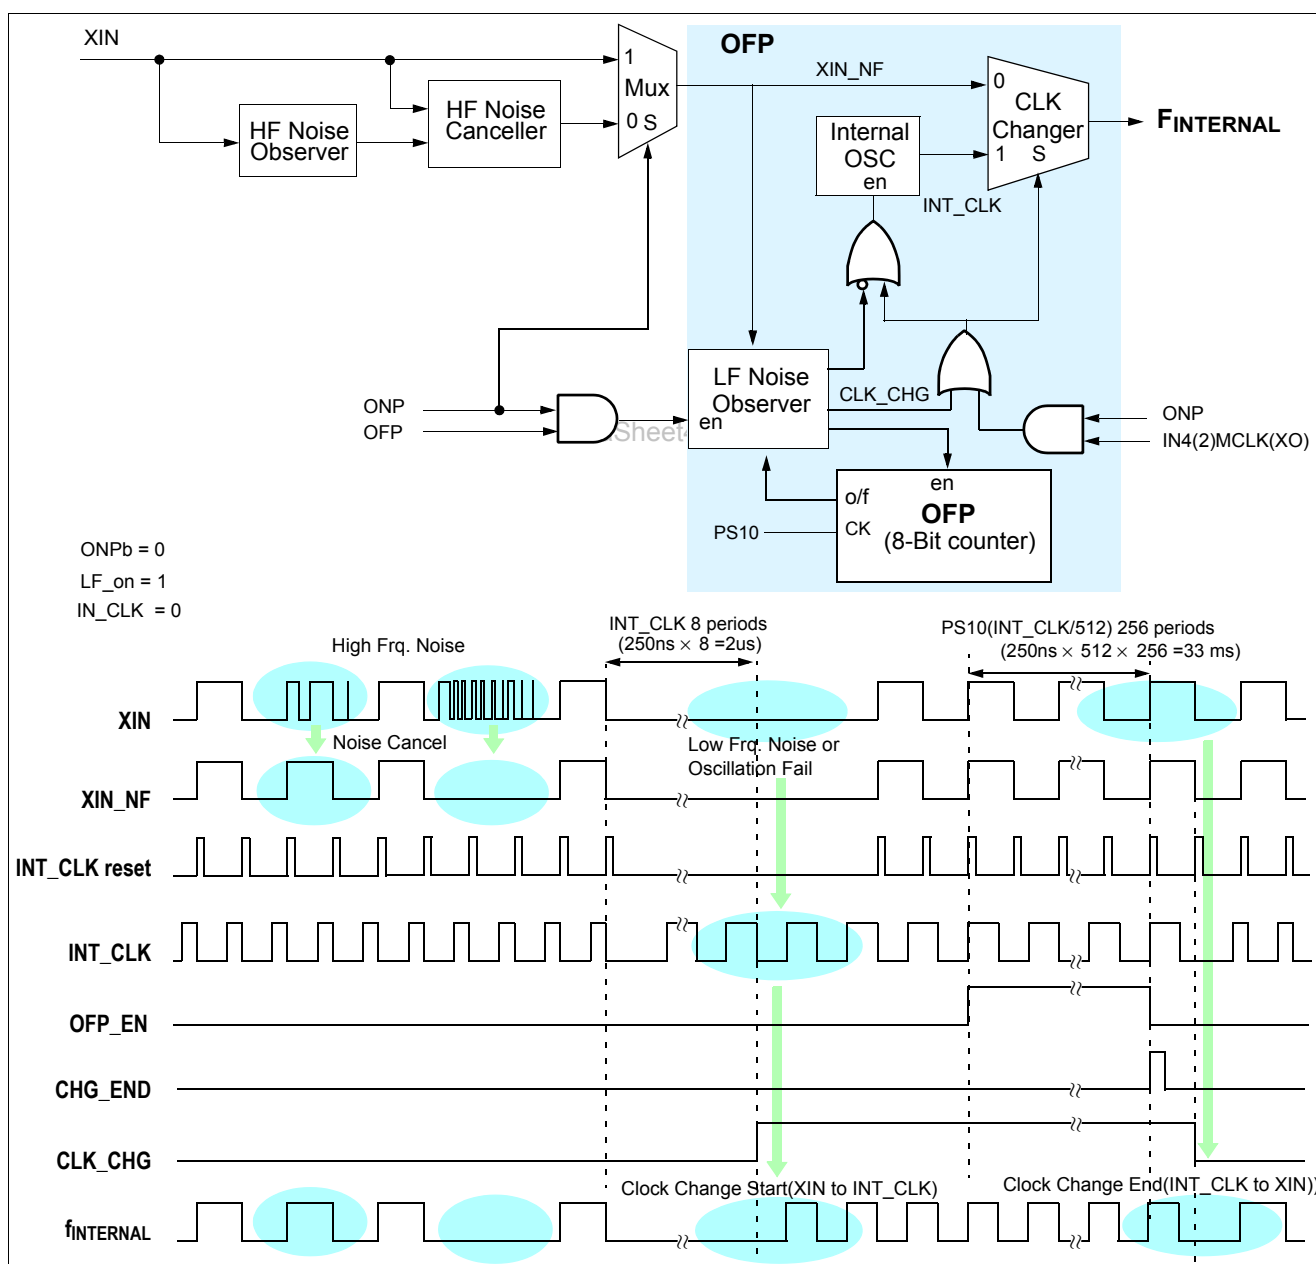

Figure 22-1 Block Diagram of ONP & OFF and Respective Wave Forms

22.2 Oscillation Fail Processor

The oscillation fail processor (OFP) can change the clock source from external to internal oscillator when the oscillation fail occurred. This function could be enabled or disabled by the “OFP” bit of the Device Configuration Area (MASK option for HMS83C012/022).

And this function can recover the external clock source when the external clock is recovered to normal state.

IN4(2)MCLK/CLKXO(XO) Option

The “IN4MCLK(XO)”, “IN2MCLK(XO)” bit of the De-

vice Configuration Area (MASK option for HMS83C012/022) enables the function to operate the device by using the internal oscillator clock in ONP block as system clock. There is no need to connect the x-tal, resonator, RC and R externally. The user only to connect the X_{IN} pin to V_{DD}. After selecting the this option, the period of internal oscillator clock could be checked by X_{OUT} outputting clock divided the internal oscillator clock by 4.

23. Device Configuration Area

The Device Configuration Area can be programmed or left unprogrammed to select device configuration such as POR, ONP, CLK option and security bit. This area is not

accessible during normal execution but is readable and writable during FLASH program / verify mode.

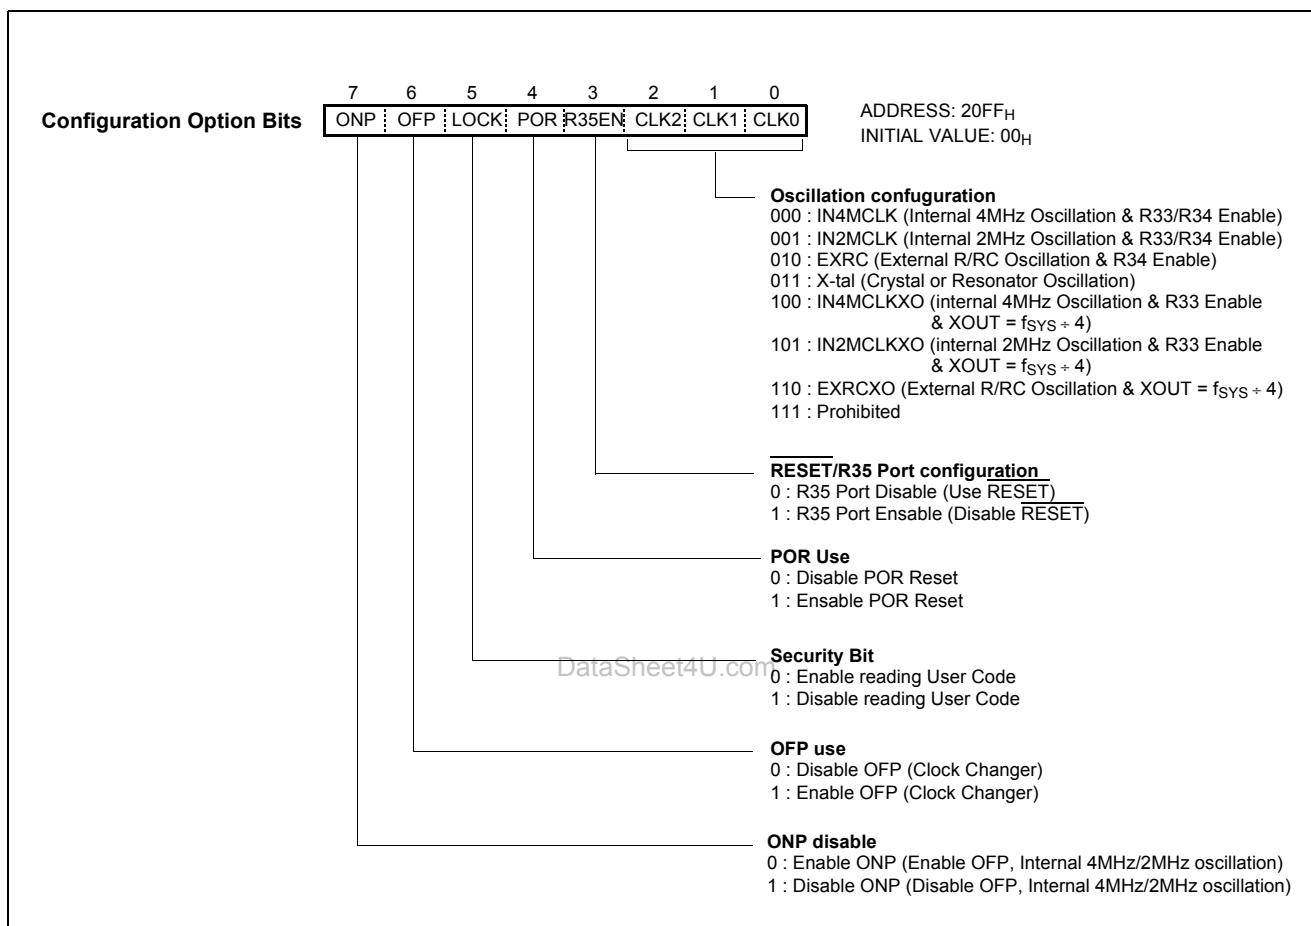

Figure 23-1 Device Configuration Area

24. MASK Option (MC80C0316)

The MC80C0316 has several MASK option which configures the package type or use of some special features of the device. The MASK option of the MASK order sheet should be checked to select device configuration such as

package type, Oscillation selection, oscillation noise protector, oscillation fail protector, internal 4MHz, amount of noise to be cancelled.

	Option	Check	Operation	Remark
MASK Option	Package	28 SKDIP	28 SKDIP type package select	
		32 PDIP	32 PDIP type package select	
	ONP	Yes	ONP Enable	OSC Noise Protector(ONP) Operation En/Disable Bit
		No	ONP Disable	
	OFP	Yes	Enables Oscillation Fail Processor (ONP clock changer)	Change the Inter clock when oscillation failed
		No	Disables Oscillation Fail Processor (ONP clock changer)	
	POR	Yes	Enables POR	To select Power-on Reset
		No	Disables POR	
	R35EN	Yes	R35 port Enable (Disable $\overline{\text{RESET}}$)	To use R35 port as nomarl input port
		No	R35 port Disable (Use $\overline{\text{RESET}}$)	
	CLK option	Crystal	Crystal Oscillation	To select Oscillation Type
		EXRC	External R/RC oscillation & R33 Enable	
		IN4MCLK	Internal 4MHz Oscillation & R33/R34 Enable	
		IN2MCLK	Internal 2MHz Oscillation & R33/R34 Enable	
EXRCXO		External R/RC oscillation & R33 Enable X _{OUT} Pin : System clock ÷ 4		
IN4MCLKXO		Internal 4MHz Oscillation & R33 Enable X _{OUT} Pin : System clock ÷ 4		
	IN2MCLKXO	Internal 2MHz Oscillation & R33 Enable X _{OUT} Pin : System clock ÷ 4

DIP Switch and VR Setting

low configuration

Before execute the user program, keep in your mind the be-

DIP S/W	Description	ON/OFF Setting		
1	-	This connector is only used for a device over 32 PIN. For the HMS83F027/25/23.		
2	-	This connector is only used for a device under 32 PIN. For the MC80F0316.		
3 SW2	1	 ON Eva. select switch	Must be OFF position. ON : For the HMS83F027/25/23. OFF : For the MC80F0316.	
	2 3	 ON OFF Use Eva. V _{DD}	 OFF ON Use User's AV _{DD}	These switches select the AV _{DD} source. ON & OFF : Use Eva. V _{DD} OFF & ON : Use User AV _{DD}
	4	This switch select the /Reset source.	Normally OFF . EVA. chip can be reset by external user target board. ON : Reset is available by either user target system board or Emulator RESET switch. OFF : Reset the MCU by Emulator RESET switch. Does not work from user target board.	
	5	This switch select the Xout signal on/off.	Normally OFF . MCU XOUT pin is disconnected internally in the Emulator. Some circumstance user may connect this circuit. ON : Output XOUT signal OFF : Disconnect circuit	
	4 SW3	1	 MDS ↑ USER Use MDS Power	 MDS ↓ USER Use User's Power
5 SW4	1 2	This switch select the R22 or SX _{OUT} . This switch select the R21 or SX _{IN} .	These switches select the Normal I/O port(off) or Sub-Clock (on). It is reserved for the MC80F0448. ON : SX _{OUT} , SX _{IN} OFF : R22, R21 Don't care (HMS83F027/25/23).	

DIP S/W		Description	ON/OFF Setting
⑥ SW5	1 2	These switches select the R33 or X _{IN}	This switch select the Normal I/O port(on&off) or special function select(off&on). It is reserved for the MC80F0316. ON & OFF : R33,R34,R35 Port selected. OFF & ON : X _{OUT} , X _{IN} , /Reset selected. Don't care (HMS83F027/25/23).
	3 4	These switches select the R34 or X _{OUT}	
	5 6	These switches select the R35 or /Reset	
⑦	-	This is External oscillation socket(CAN Type. OSC)	This is for External Clock(CAN Type. OSC).

26. IN-SYSTEM PROGRAMMING (ISP)

26.1 Getting Started / Installation

The following section details the procedure for accomplishing the installation procedure.

1. Connect the serial(RS-232C) cable between a target board and the COM port of your PC.
2. Configure the COM port of your PC as following.
3. Turn your target B/D power switch ON. Your target B/D must be configured to enter the ISP mode.
4. Run the MagnaChip ISP software.
5. Press the Reset Button in the ISP S/W. If the status windows shows a message as "Connected", all the conditions for ISP are provided.

Baudrate	115,200
Data bit	8
Parity	No
Stop bit	1
Flow control	No

26.2 Basic ISP S/W Information

Function	Description
Load HEX File	Load the data from the selected file storage into the memory buffer.
Save HEX File	Save the current data in your memory buffer to a disk storage by using the Intel Motorola HEX format.
Erase	Erase the data in your target MCU before programming it.
Blank Check	Verify whether or not a device is in an erased or unprogrammed state.
Program	This button enables you to place new data from the memory buffer into the target device.
Read	Read the data in the target MCU into the buffer for examination. The checksum will be displayed on the checksum box.
Verify	Assures that data in the device matches data in the memory buffer. If your device is secured, a verification error is detected.
Option Write	Program the configuration data of target MCU. The security locking is performed with this button.
Option	Set the configuration data of target MCU. The security locking is set with this button.
AUTO	Erase & Program & Verify.
Auto Option Write	If selected with check mark, the option write is performed after erasure and write.
Edit Buffer	Modify the data in the selected address in your buffer memory
Fill Buffer	Fill the selected area with a data.
Goto	Display the selected page.
OSC. _____ MHz	Enter your target system's oscillator value with discarding below point.
Start _____	Starting address
End _____	End address
Checksum	Display the checksum(Hexdecimal) after reading the target device.
Com Port	Select serial port.
Baud Rate	Select UART baud rate.
Select Device	Select target device.
Page Up Key	Display the previous page of your memory buffer.
Page Down Key	Display the higher page than the current location.

Table 1. ISP Function Description

26.3 Hardware Conditions to Enter the ISP Mode

The In-System Programming (ISP) is performed without removing the microcontroller from the system. The In-System Programming (ISP) facility consists of a series of internal hardware resources coupled with internal firmware through the serial port. The In-System Programming (ISP) facility has made in-circuit programming in an em-

bedded application possible with a minimum of additional expense in components and circuit board area. The boot loader can be executed by holding $\overline{\text{ALE}}$ high, $\overline{\text{RESET}}/\text{V}_{\text{PP}}$ as +9V, and ACLK with the OSC. 1.8432MHz. The ISP function uses five pins: TxD, RxD, ALEB, ACLK and $\overline{\text{RESET}}/\text{V}_{\text{PP}}$.

Note: Considerations to implement ISP function in a user target board

- The ACLK must be connected to the specified oscillator.
- Connect the +9V to $\overline{\text{RESET}}/\text{V}_{\text{PP}}$ pin directly.
- The $\overline{\text{ALE}}$ pin must be pulled high.
- The main clk must be higher than 2MHz.

26.4 Reference ISP Circuit Diagram and MagnaChip Supplied ISP Board

The ISP software and hardware circuit diagram are provided at www.magnachipmcu.com. To get a ISP B/D, contact to sales department. The following circuit diagram is for reference use.
