DESCRIPTION

The AZ10/100E116 is a quint differential line receiver with emitter-follower outputs. The E116 provides a V_{BB} output for single-ended use or a DC bias reference for AC coupling to the device. For single-ended input applications, the V_{BB} reference should be connected to one side of the D_n/\bar{D}_n differential input pair. The input signal is then fed to the other D_n/\bar{D}_n input. The V_{BB} pin should be used only as a bias for the E116 as its sink/source capability is limited. When used, the V_{BB} pin should be bypassed to ground via a 0.01 μ F capacitor.

The receiver design features clamp circuitry to cause a defined state if both the inverting and non-inverting inputs are left open; in this case the Q output goes LOW, while the \bar{Q} output goes HIGH. This feature makes the device ideal for twisted pair applications.

If both inverting and non-inverting inputs are at an equal potential of $> V_{CC} - 2.5V$, the receiver does not go to a defined state. This condition may produce output voltage levels between HIGH and LOW.

NOTE: Specifications in ECL/PECL tables are valid when thermal equilibrium is established.

- Within-device skew is defined as identical transitions on similar paths through a device.
- Duty cycle skew is defined only for differential operation. The skews are measured from the crossover point of the inputs to the crossover point of the outputs.
- V_{PP} is the minimum peak-to-peak differential input swing for which AC parameters are guaranteed.
- The V_{CMR} range is referenced to the most positive side of the differential input signal. Normal operation is obtained if the HIGH level falls within the specified range and the peak-to-peak voltage lies between $V_{PP}(\text{min})$ and 1V .
