# Active Clamp Synchronous Forward Controller 

## feATURES

- Input Voltage Range: 8.5 V to 100 V
- Programmable Volt-Second Clamp
- High Efficiency Control: Active Clamp, Synchronous Rectification, Programmable Delays
- Short-Circuit (Hiccup Mode) Overcurrent Protection
- Programmable Soft-Start/Stop
- Programmable OVLO and UVLO with Hysteresis
- Programmable Frequency ( 100 kHz to 500 kHz )
- Synchronizable to an External Clock

## APPLICATIONS

- Industrial, Automotive and Military Systems
- 48V Telecommunication Isolated Power Supplies

## DESCRIPTION

The LT®3753 is a current mode PWM controller optimized for an active clamp forward converter topology, allowing up to 100 V input operation.
A programmable volt-second clamp allows primary switch duty cycles above $50 \%$ for high switch, transformer and rectifier utilization. Active clamp control reduces switch voltage stress and increases efficiency. A synchronous output is available for controlling secondary side synchronous rectification.

The LT3753 is available in a 38 -lead plastic TSSOP package with missing pins for high voltage spacings.

$\boldsymbol{\Sigma}$, LT, LTC, LTM, Linear Technology and the Linear logo are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

## TYPICAL APPLICATION

36V to 72V, 5V/20A Active Clamp Isolated Forward Converter

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: The LT3753EFE is guaranteed to meet performance specifications from $0^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ junction temperature. Specifications over the $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ operating junction temperature range are assured by design, characterization and correlation with statistical process controls. The LT3753IFE is guaranteed to meet performance specifications from $-40^{\circ} \mathrm{C}$ to $125^{\circ} \mathrm{C}$ junction temperature. The LT3753HFE is guaranteed to meet performance specifications from $-40^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ junction temperature. The LT3753MPFE is tested and guaranteed to meet performance specifications from $-55^{\circ} \mathrm{C}$ to $150^{\circ} \mathrm{C}$ junction temperature.
Note 3: For maximum operating ambient temperature, see the Thermal Calculations section in the Applications Information section.
Note 4: SYNC minimum and maximum thresholds are guaranteed by SYNC frequency range test using a clock input with guard banded SYNC levels of 0.7 V low level and 1.7 V high level.

Note 5: Rise and fall times are measured between $10 \%$ and $90 \%$ of gate driver supply voltage.
Note 6: Guaranteed by design.
Note 7: ON times are measured between rising and falling edges at $50 \%$ of gate driver supply voltage.
Note 8: Current flows out of pin.
Note 9: Guaranteed by correlation to $\mathrm{R}_{\text {TAS }}=73.2 \mathrm{k}$ test.
Note 10: $t_{0 \mathrm{~A}}$ timing guaranteed by design based on correlation to measured $\mathrm{t}_{\mathrm{AO}}$ timing.
Note 11: Guaranteed by correlation to $\mathrm{R}_{\text {TAO }}=44.2 \mathrm{k}$ test.
Note 12: Guaranteed by correlation to $R_{T O S}=14.7 \mathrm{k}$ test.

## PIn fUnCTIONS

TEST1 (Pin 1): Connect to GND.
NC (Pins 2, 15, 16, 34, 37): No Connect Pins. These pins are not connected inside the IC. These pins should be left open.

RT (Pin 3): A resistor to ground programs switching frequency.
FB (Pin 4): Error Amplifier Inverting Input.
COMP (Pin 5): Error Amplifier Output. Allows various compensation networks for nonisolated applications.
SYNC (Pin 6): Allows synchronization of internal oscillator to an external clock. fisync equal to $\mathrm{f}_{\mathrm{OSC}}$ allowed.
SS1 (Pin 7): Capacitor controls soft-start/stop of switching frequency and volt-second clamp. During soft-stop it also controls the COMP pin.
IVSEC (Pin 8): Resistor Programs OUT Pin Maximum Duty Cycle Clamp (DVSEC). This clamp moves inversely proportional to system input voltage to provide a voltsecond clamp.

UVLO_V $\mathbf{V E C C}^{(P i n} 9$ ): A resistor divider from system input allows switch maximum duty cycle to vary inversely proportional with system input. This volt-second clamp prevents transformer saturation for duty cycles above $50 \%$. Resistor divider ratio programs undervoltage lockout (UVLO) threshold. A $5 \mu \mathrm{~A}$ pin current hysteresis allows programming of UVLO hysteresis. Pin below 0.4 V reduces $\mathrm{V}_{\text {IN }}$ currents to microamps.
OVLO (Pin 10): A resistor divider from system input programs overvoltage lockout (OVLO) threshold. Fixed hysteresis included.
$\mathrm{T}_{\mathrm{AO}}$ (Pin 11): A resistor programs nonoverlap timing between AOUT rise and OUT rise control signals.
$\mathrm{T}_{\text {AS }}$ (Pin 12): Resistors at $\mathrm{T}_{A O}$ and $\mathrm{T}_{\text {AS }}$ define delay between SOUT fall and OUT rise ( $=\mathrm{t}_{\mathrm{AO}}-\mathrm{t}_{\mathrm{AS}}$ ).
Tos (Pin 13): Resistor programs delay between OUT fall and SOUT rise.

TBLNK (Pin 14): Resistor programs extended blanking of ISENSEP and OC signals during MOSFET turn-on.

SS2 (Pin 17): Capacitor controls soft-start of COMP pin. Alternatively can connect to OPTO to communicate start of switching to secondary side. If unused, leave the pin open.
GND (Pin 18): Analog Signal Ground. Electrical connection exists inside the IC to the exposed pad (Pin 39).

PGND (Pins 19, 38, 39): The Power Grounds for the IC. The package has an exposed pad (Pin 39) underneath the IC which is the best path for heat out of the package. Pin 39 should be soldered to a continuous copper ground plane under the device to reduce die temperature and increase the power capability of the LT3753.
ISENSEN (Pin 20): Negative input for the current sense comparator. Kelvin connect to the sense resistor in the source of the power MOSFET.
I ${ }_{\text {SENSEP }}$ (Pin 21): Positive input for the current sense comparator. Kelvin connect to the sense resistor in the source of the power MOSFET. A resistor in series with $I_{\text {SENSEP }}$ programs slope compensation.
OC (Pin 22): An accurate 96 mV threshold, independent of duty cycle, for detection of primary side MOSFET overcurrent and trigger of hiccup mode. Connect directly to sense resistor in the source of the primary side MOSFET.

Missing Pins 23, 25, 27, 29, 31, 33, 35: Pins removed for high voltage spacings and improved reliability.

OUT (Pin 24): Drives the gate of an N-channel MOSFET between OV and INTV ${ }_{c c}$. Active pull-off exists in shutdown.
INTV $_{\text {CC }}$ (Pin 26): A linear regulator supply generated from $V_{I N}$. Supplies 10 V for AOUT, SOUT and OUT gate drivers. INTV ${ }_{\text {CC }}$ must be bypassed with a $4.7 \mu \mathrm{~F}$ capacitor to power ground. Can be externally driven by the housekeeping supply to remove power from within the IC.
$\mathbf{V}_{\text {IN }}$ (Pin 28): Input Supply Pin. Bypass with $1 \mu \mathrm{~F}$ to ground.
SOUT (Pin 30): Sync signal for secondary side synchronous rectifier controller.

AOUT (Pin 32): Control signal for external active clamp switch.

TEST2 (Pin 36): Connect to GND.

## OPERATION

## Introduction

The LT3753 is a primary side, current mode, PWM controller optimized for use in a synchronous forward converter with active clamp reset. The LT3753 allows $\mathrm{V}_{\text {IN }}$ pin operation between 8.5 V and 100 V . The LT3753 based forward converter is targeted for power levels up to 400 W and is not intended for battery charger applications. For higher powerlevels the converter outputs can be stacked in series. Connecting UVLO_V ${ }_{\text {SEC }}$ pins, OVLO pins, SS1 pins and SS2 pins together allows blocks to react simultaneously to all fault modes and conditions.

The IC contains an accurate programmable volt-second clamp. When set above the natural duty cycle of the converter, it provides a duty cycle guardrail to limit primary switch reset voltage and prevent transformer saturation during load transients. The accuracy and excellent line regulation of the volt-second clamp provides $\mathrm{V}_{\text {OUT }}$ regulation for open-loop conditions such as no opto-coupler, reference or error amplifier on the secondary side.
For applications not requiring isolation but requiring high step-down ratios, each IC contains a voltage error amplifier to allow a very simple nonisolated, fully regulated synchronous forward converter.
A range of protection features include programmable overcurrent (OC) hiccup mode, programmable system input undervoltage lockout (UVLO), programmable system input overvoltage lockout (OVLO) and built-in
thermal shutdown. Programmable slope compensation and switching frequency allow the use of a wide range of output inductor values and transformer sizes.

## Part Start-Up

LT3753 start-up is best described by referring to the Block Diagram and to the start-up waveforms in Figure 3. For part start-up, system input voltage must be high enough to drive the UVLO_V $\mathrm{V}_{\text {SEC }}$ pin above 1.25 V and the $\mathrm{V}_{\text {IN }}$ pin must be greater than 8.5 V . An internal linear regulator is activated and provides a 10 V INTV ${ }_{\text {CC }}$ supply for all gate drivers. The SS1 pin of the forward controller is allowed to start charging when INTV ${ }_{C C}$ reaches its 7 V UVLO(+) thershold. When SS1 reaches 1.25 V , the SS2 pin begins to charge, controlling COMP pin rise and the soft-start of output inductor peak current. The SS1 pin independently soft starts switching frequency and a volt-second clamp from $22 \%$ of their full-scale programmed values.
If secondary side control already exists for soft starting the converter output voltage then the SS2 pin can still be used to control initial inductor peak current rise. Simply programming the primary side SS2 soft-start faster than the secondary side allows the secondary side to take over. If SS2 is not needed for soft-start control, its pull-down strength and voltage rating also allow it to drive the input of an opto-coupler connected to INTV ${ }_{\text {CC }}$. This allows the option of communicating to the secondary side that switching has begun.

## APPLICATIONS INFORMATION

## Programming System Input Undervoltage Lockout (UVLO) Threshold and Hysteresis

The LT3753 has an accurate 1.25 V shutdown threshold at the UVLO_V ${ }_{\text {SEC }}$ pin. This threshold can be used in conjunction with an external resistor divider to define the falling undervoltage lockout threshold (UVLO(-)) for the converter's system input voltage $\left(\mathrm{V}_{S}\right)$ (Figure 4). A pin hysteresis current of $5 \mu \mathrm{~A}$ allows programming of the UVLO(+) threshold.
$\mathrm{V}_{\mathrm{S}}$ (UVLO(-)) [begin SOF-STOP then shut down]

$$
\begin{aligned}
& =1.25\left[1+\left(\frac{\mathrm{R} 1}{\mathrm{R} 2+\mathrm{R} 3}\right)\right] \\
& \mathrm{V}_{\mathrm{S}}(\mathrm{UVLO}(+))[\text { begin SOF-START }] \\
& =\mathrm{V}_{\mathrm{S}}(\mathrm{UVLO}(-))+(5 \mu \mathrm{~A} \cdot \mathrm{R} 1)
\end{aligned}
$$

It is important to note that the part enters soft-stop when the UVLO_V ${ }_{\text {SEC }}$ pin falls back below 1.25 V . During soft-stop the converter continues to switch as itfolds back switching frequency, volt-second clamp and COMP pin voltage. See Soft-Stop in the Applications Information section. When the SS2 pin is finally discharged below its 150 mV reset threshold the forward converter is shut down.

Figure 4. Programming Undervoltage Lockout (UVLO)

## Soft-Stop Shutdown

Soft-stop shutdown (similar to system undervoltage) can be commanded by an external control signal. A MOSFET with a diode (or diodes) in series with the drain should be used to pull down the UVLO_V ${ }_{\text {SEC }}$ pin below 1.25 V but not below the micropower shutdown threshold of 0.6 V (max). Typical $\mathrm{V}_{\mathrm{IN}}$ quiescent current after soft-stop is $165 \mu \mathrm{~A}$.

## Micropower Shutdown

If a micropower shutdown is required using an external control signal, an open-drain transistor can be directly connected to the UVLO_V ${ }_{\text {SEC }}$ pin. The LT3753 has a micropower shutdown threshold of typically 0.4 V at the UVLO_V ${ }_{\text {SEC }}$ pin. $\mathrm{V}_{\text {IN }}$ quiescent current in micropower shutdown is $20 \mu \mathrm{~A}$.

## Programming System Input Overvoltage Lockout (OVLO) Threshold

The LT3753 has an accurate 1.25 V overvoltage shutdown threshold at the OVLO pin. This threshold can be used in conjunction with an external resistor divider to define the rising overvoltage lockout threshold (OVLO(+)) for the converter's system input voltage ( $\mathrm{V}_{S}$ ) (Figure 5). When OVLO(+) is reached, the part stops switching immediately and a hard stop discharges the SS1 and SS2 pins. The falling threshold OVLO(-) is fixed internally at 1.205 V and allows the part to restart in soft-start mode. A single resistor divider can be used from system input supply ( $\mathrm{V}_{\mathrm{S}}$ ) to define both the undervoltage and overvoltage thresholds for the system. Minimum value for R3 is 1 k . If OVLO is unused, place a 10 k resistor from OVLO pin to ground.

$$
\begin{aligned}
& \text { V }_{\text {S OVLO }} \text { (+) [stop switching; HARD STOP] } \\
& =1.25\left[1+\left(\frac{\mathrm{R} 1+\mathrm{R} 2}{\mathrm{R} 3}\right)\right] \\
& \mathrm{V}_{\mathrm{S}} \text { OVLO(-) [begin SOFT-START] } \\
& =\mathrm{V}_{\mathrm{S}} \text { OVLO }(+) \cdot \frac{1.215}{1.25}
\end{aligned}
$$

## APPLICATIONS INFORMATION

Figure 5. Programming Overvoltage Lockout (OVLO)

## Programming Switching Frequency

The switching frequency for the LT3753 is programmed using a resistor, $\mathrm{R}_{\mathrm{T}}$, connected from analog ground (Pin 18) to the RT pin. Table 1 shows typical $\mathrm{f}_{\mathrm{OSc}}$ vs $\mathrm{R}_{T}$ resistor values. The value for $R_{T}$ is given by:

$$
\mathrm{R}_{\mathrm{T}}=8.39 \bullet \mathrm{X} \cdot(1+\mathrm{Y})
$$

where,

$$
\begin{aligned}
& X=\left(10^{9} / f_{0 S C}\right)-365 \\
& Y=\left(300 \mathrm{kHz}-\mathrm{f}_{\mathrm{OSC}}\right) / 10^{7} \quad\left(\mathrm{f}_{\mathrm{OSC}}<300 \mathrm{kHz}\right) \\
& Y=\left(\mathrm{f}_{\mathrm{OSC}}-300 \mathrm{kHz}\right) / 10^{7} \quad\left(\mathrm{f}_{\text {OSC }}>300 \mathrm{kHz}\right)
\end{aligned}
$$

Example: For $\mathrm{f}_{0 S \mathrm{C}}=200 \mathrm{kHz}$,

$$
\mathrm{R}_{\mathrm{T}}=8.39 \bullet 4635 \bullet(1+0.01)=39.28 \mathrm{k} \text { (choose } 39.2 \mathrm{k} \text { ) }
$$

The LT3753 includes frequency foldback at start-up (see Figure 3). In order to make sure that a SYNC input does not override frequency foldback during start-up, the SYNC function is ignored until SS1 pin reaches 2.2 V .

Table 1. $\mathrm{R}_{\mathrm{T}}$ vs Switching Frequency ( $\mathrm{f}_{\mathrm{OSc}}$ )

| SWITCHING FREQUENCY (kHz) | $\mathbf{R}_{\mathbf{T}} \mathbf{( k \boldsymbol { \Omega } )}$ |
| :---: | :---: |
| 100 | 82.5 |
| 150 | 53.6 |
| 200 | 39.2 |
| 250 | 30.9 |
| 300 | 24.9 |
| 350 | 21 |
| 400 | 18.2 |
| 450 | 15.8 |
| 500 | Choose 13.7 |

## Synchronizing to an External Clock

The LT3753 internal oscillator can be synchronized to an external clock at the SYNC pin. SYNC pin high level should exceed 1.8 V for at least 100 ns and SYNC pin low level should fall below 0.6 V for at least 100 ns . The SYNC pin frequency should be set equal to or higher than the typical frequency programmed by the RT pin. An fiync/fosc ratio of $x(1.0<x<1.25)$ will reduce the externally programmed slope compensation by a factor of $1.2 x$. If required, the external resistor $\mathrm{R}_{\text {ISLP }}$ can be reprogrammed higher by a factor of $1.2 x$. (see Current Sensing and Programmable Slope Compensation).

The part injection locks the internal oscillator to every rising edge of the SYNC pin. If the SYNC input is removed at any time during normal operation the part will simply change switching frequency backto the oscillator frequency programmed by the $\mathrm{R}_{\top}$ resistor. This injection lock method avoids the possible issues from a PLL method which can potentially cause a large drop in frequency if SYNC input is removed.

During soft-start the SYNC input is ignored until SS1 exceeds 2.2V. During soft-stop the SYNC input is completely ignored. If the SYNC input is to be used, recall that the programmable duty cycle clamp $D_{\text {VSEC }}$ is dependent on the switching frequency of the part (see section Programming Duty Cycle Clamp). RIVSEC should be reprogrammed by $1 / x$ for an $f_{S Y N C} / f_{\text {OSC }}$ ratio of $x$.

## INTV $_{\text {cc }}$ Regulator Bypassing and Operation

The INTV ${ }_{C C}$ pin is the output of an internal linear regulator driven from $\mathrm{V}_{\mathrm{IN}_{N}}$ and provides a 10 V supply for onboard gate drivers AOUT, SOUT and OUT. INTV CC should be bypassed with a $4.7 \mu \mathrm{~F}$ low ESR, X7R or X5R ceramic capacitor to power ground to ensure stability and to provide enough charge for the gate drivers.

The INTV ${ }_{C C}$ regulator has a minimum 19 mA output current limit. This current limit should be considered when choosing the switching frequency and capacitance loading on each gate driver. Average current load on the INTV ${ }_{C C}$ pin for a single gate driver driving an external MOSFET is given as:

$$
I_{\text {INTVCC }}=f_{O S C} \bullet Q_{G}
$$

## APPLICATIONS INFORMATION

where:

$$
\begin{aligned}
& \mathrm{f}_{\mathrm{OSC}}=\text { controller switching frequency } \\
& Q_{G}=\text { gate charge }\left(\mathrm{V}_{\mathrm{GS}}=\operatorname{INTV} \mathrm{V}_{\mathrm{CC}}\right)
\end{aligned}
$$

While the INTV $_{\text {CC }}$ 19mA output current limit is sufficient for LT3753 applications, efficiency and internal power dissipation should also be considered. INTV CC can be externally overdriven by an auxiliary supply (see Generating Auxiliary Supplies in the Applications Information section) to improve efficiency, remove power dissipation from within the IC and provide more than 19mA output current capability. Any overdrive level should exceed the regulated INTV CC level but not exceed 16 V .
In the case of a short-circuit fault from INTV ${ }_{\text {CC }}$ to ground, the IC reduces the INTV ${ }_{\text {CC }}$ output current limit to typically 13 mA . The INTV ${ }_{C C}$ regulator has an undervoltage lockout rising threshold, UVLO(+), which prevents gate driver switching until INTV ${ }_{\text {CC }}$ reaches 7 V and maintains switching until INTV ${ }_{\text {CC }}$ falls below a UVLO(-) threshold of 6.8 V .

For $\mathrm{V}_{\text {IN }}$ levels close to or below the INTV ${ }_{C C}$ regulated level, the INTV ${ }_{C C}$ linear regulator may enter dropout. The resulting lower INTV ${ }_{\text {CC }}$ level will still allow gate driver switching as long as INTV ${ }_{\text {Cc }}$ remains above INTV ${ }_{\text {CC }}$ UVLO(-) levels. See the Typical Performance Characteristics section for INTV ${ }_{\text {CC }}$ performance vs $\mathrm{V}_{\text {IN }}$ and load current.

## Adaptive Leading Edge Blanking Plus Programmable Extended Blanking

The LT3753 provides a $\pm 2$ A gate driver at the OUT pin to control an external N-channel MOSFET for main power delivery in the forward converter (Figure 7). During gate rise time and sometime thereafter, noise can be generated in the current sensing resistor connected to the source of the MOSFET. This noise can potentially cause a false trip of sensing comparators resulting in early switch turn off and in some cases re-soft-start of the system. To prevent this, LT3753 provides adaptive leading edge blanking of both OC and I ISENSEP signals to allow a wide range of MOSFET $Q_{G}$ ratings. In addition, a resistor $\mathrm{R}_{\text {TBLNK }}$ connected from TBLNK pinto analog ground (Pin 18) programs an extended blanking duration (Figure 6).

Figure 6. Adaptive Leading Edge Blanking Plus Programmable Extended Blanking

Figure 7. Current Sensing and Programmable Slope Compensation

Adaptive leading edge blanking occurs from the start of OUT rise and completes when OUT reaches within 1 V of its maximum level. An extended blanking then occurs which is programmable using the $\mathrm{R}_{\text {TBLNK }}$ resistor given by:

$$
\mathrm{t}_{\mathrm{BLNK}}=50 \mathrm{~ns}+\left(\frac{2.2 \mathrm{~ns}}{\mathrm{k}} \cdot \mathrm{R}_{\mathrm{TBLNK}}\right),
$$

### 7.32 k < $\mathrm{R}_{\text {TBLNK }}<249 \mathrm{k}$

Adaptive leading edge blanking minimizes the value required for $\mathrm{R}_{\text {TBLNK. }}$. Increasing $\mathrm{R}_{\text {TBLNK }}$ furtherthan required increases M1 minimum on time (Figure 7).

In addition, the critical volt-second clamp (DVSEC) is not blanked. Therefore, if $D_{\text {VSEC }}$ decreases far enough (in soft start foldback and at maximum input voltage) M1 may turn off before blanking has completed. Since OC and ISENSEP signals are only seen when M1 is on (and after blanking has completed), $\mathrm{R}_{\text {TBLNK }}$ value should be limited by:
$(2.2 \mathrm{~ns} / \mathrm{k}) \mathrm{R}_{\text {TBLNK }}<\mathrm{T}_{\text {VSEC(MIN })}-\mathrm{t}_{\text {ADAPTIVE }}-50 \mathrm{~ns}$

## APPLICATIONS INFORMATION

where,
$T_{\text {VSEC(MIN) }}=10^{9}($ DVSEC (MAX) $/($ fold.fosc $))$

- Input $\left._{\text {(MIN }}\right)^{\prime}$ Input $\left._{(\text {MAX })}\right)$
fold $=f_{\text {OSC }}$ and DVSEC foldback ratio (for OUT pin)
$t_{\text {ADAPTIVE }}=$ OUT pin rise time to INTV $_{\text {CC }}-1 \mathrm{~V}$
Example: For Figure 22 circuit, $\mathrm{DVSEC}_{\text {VAAX }}=0.77$, $\operatorname{Input}_{(\text {MIN }) /(\text { MAX })}=17.4 \mathrm{~V} / 74 \mathrm{~V}$, fold $=4, \mathrm{t}_{\text {ADAPTIVE }}=23 \mathrm{~ns}$ and $\mathrm{f}_{\mathrm{OSC}}=240 \mathrm{kHz}$,
$T_{\text {VSEC (MIN })}=10^{9}\left(0.77 /\left(4 \cdot 2.4 \cdot 10^{5}\right)\right) \cdot 17.4 / 74=188 \mathrm{~ns}$
(2.2ns/1k) $\mathrm{R}_{\text {TBLNK }}<188-23-50$
$\mathrm{R}_{\text {TBLNK }}<52.5 \mathrm{k}$ (Actual Circuit Uses 34k)

## Current Sensing and Programmable Slope Compensation

The LT3753 commands cycle-by-cycle peak current in the external switch and primary winding of the forward transformer by sensing voltage across a resistor connected in the source of the external n-channel MOSFET (Figure 7).

The sense voltage across $\mathrm{R}_{\text {SENSE }}$ is compared to a sense threshold at the I SENSEP pin, controlled by COMP pin level. Two sense inputs, $I_{\text {SENSEP }}$ and $I_{\text {SENSEN }}$, are provided to allow a Kelvin connection to R RENSE. For operation in continuous mode and above 50\% duty cycle, required slope compensation can be programmed by adding a resistor, $\mathrm{R}_{\text {ISLP }}$, in series with the $I_{\text {SENSEP }}$ pin. A ramped current always flows out of the I ISENSE pin. The current starts from $2 \mu \mathrm{~A}$ at $0 \%$ duty cycle and linearly ramps to $33 \mu \mathrm{~A}$ at $80 \%$ duty cycle. A good starting value for $\mathrm{R}_{\text {ISLP }}$ is $1.5 \mathrm{k} \Omega$ which gives a 41 mV total drop in current comparator threshold at $65 \%$ duty cycle.

The COMP pin commands an ISENSEP threshold between 0 mV and 220 mV . The 220 mV allows a large slope compensation voltage drop to exist in $\mathrm{R}_{\text {ISLP }}$ without effecting the programming of $R_{\text {SENSE }}$ to set maximum operational currents in M1. An fSYNc/fosc ratio of $x(1.0<x<1.25)$ will reduce the externally programmed slope compensation by a factor of $1.2 x$. If required, the external resistor $\mathrm{R}_{\text {ISLP }}$ can be reprogrammed higher by a factor of 1.2 x .

## Overcurrent: Hiccup Mode

The LT3753 uses a precise 96 mV sense threshold at the OC pin to detect excessive peak switch current (Figure 7). During an overload condition switching stops immediately and the SS1/SS2 pins are rapidly discharged. The absence of switching reduces the sense voltage at the OC pin, allowing SS1/SS2 pins to recharge and eventually attempt switching again. The part exists in this hiccup mode as long as the overcurrent condition exists. This protects the converter and reduces power dissipation in the components (see Hard Stop in the Applications Information section). The 96 mV peak switch current threshold is independent of the voltage drop in $\mathrm{R}_{\text {ISLP }}$ used for slope compensation.
Output DC load current to trigger hiccup mode:
$=I_{\text {LOAD (OVERCURRENT) }}$

$$
=\left(\frac{N_{P}}{N_{S}} \cdot \frac{96 m V}{R_{\text {ISENSE }}}\right)-\left(1 / 2 I_{\text {RIPPLE }(P-P)}\right)
$$

where:

$$
N_{P}=\text { forward transformer primary turns }
$$

$N_{S}=$ forward transformer secondary turns
$I_{\text {RIPPLE(P-P) }}=$ Output inductor peak-to-peak ripple current
$\mathrm{R}_{\text {ISENSE }}$ should be programmed to allow maximum DC Ioad current for the application plus enough margin during load transients to avoid overcurrent hiccup mode.

## Programming Maximum Duty Cycle Clamp: DVsEC (Volt-Second Clamp)

Unlike other converters which only provide a fixed maximum duty cycle clamp, the LT3753 provides an accurate programmable maximum duty cycle clamp ( $D_{\text {VSEC }}$ ) on the OUT pin which moves inversely with system input. DVSEC provides a duty cycle guardrail to limit the volt-seconds-on product over the entire

## APPLICATIONS INFORMATION

natural duty cycle range (Figures 8 and 9). This limits the drain voltage required for complete transformer reset. A resistor RIVSEC from the IVSEC pin to analog ground (Pin 18) programs DVSEC.

DVSEC (OUT pin duty cycle clamp)

$$
=0.725 \cdot \frac{R_{\text {IVSEC }}}{51.1 \mathrm{k}} \cdot \frac{\mathrm{f}_{\text {OSC }}}{300} \cdot \frac{1.25}{\mathrm{UVLO} V_{\text {SEC }}}
$$

where:
$\mathrm{R}_{\text {IVSEC }}=$ programming resistor at IVSEC pin
$\mathrm{f}_{\text {OSC }}=$ switching frequency ( kHz )
UVLO_V ${ }_{\text {SEC }}=$ resistor divided system input voltage
RIVSEC can program any DVSEC required at minimum system input. DVSEC will then follow natural duty cycle as $\mathrm{V}_{\text {IN }}$ varies. Maximum programmable $D_{\text {VSEC }}$ is typically 0.75 but may be further limited by the transformer design and voltage ratings of components connected to the drain of the primary side power MOSFET (SWP). See voltage calculations in the LO side and HI side active clamp topologies sections.

Figure 8. Volt-Second ( DVSEC ) Clamp

Figure 9. Programming DVSEC

If system input voltage falls below it's UVLO threshold the part will enter soft-stop with continued switching. The LT3753 includes an intelligent circuit which prevents DVSEC from continuing to rise as system input voltage falls (see Soft-Stop). Without this, too large a DVSEC would require extremely high reset voltages on the SWP node to properly reset the transformer. The UVLO_V ${ }_{\text {SEC }}$ pin maximum operational level is the lesser of $\mathrm{V}_{\text {IN }}-2 \mathrm{~V}$ or 12.5 V .

The LT3753 volt-second clamp architecture is superior to an external RC network connected from system input to trip an internal comparator threshold. The RC method suffers from external capacitor error, part-to-partmismatch between the RC time constant and the IC's switching period, the error of the internal comparator threshold and the nonlinearity of charging at low input voltages. The LT3753 uses the RIVSEC resistor to define the charge current for an internal timer capacitor to set an OUT pin maximum on-time, $\mathrm{t}_{\mathrm{ON} \text { (VSEC). }}$. The voltage across $\mathrm{R}_{\text {IVSEC }}$ follows UVLO_V ${ }_{\text {SEC }}$ pin voltage (divided down from system input voltage). Hence, $\mathrm{R}_{\text {IVSEC }}$ current varies linearly with input supply. The LT3753 also trims out internal timing capacitor and comparator threshold errors to optimize part-to-part matching between $\mathrm{t}_{\mathrm{ON}(\text { VSEC })}$ and T .

## DVsec Open Loop Control: No Opto-Coupler, Error Amplifier or Reference

The accuracy of the programmable volt-second clamp ( DVSEC ) safely controls $V_{\text {OUT }}$ if open loop conditions exist such as no opto-coupler, error amplifier or reference on the secondary side. DVSEC Controls the output of the converter by controlling duty cycle inversely proportional to system input. If $D_{\text {VSEC }}$ duty cycle guardrail is programmed $\mathrm{X} \%$ above natural duty cycle, VOUT will only increase by $\mathrm{X} \%$ if a closed loop system breaks open. This volt-second clamp is operational over a $10: 1$ system input voltage range. See $D_{\text {VSEC }}$ versus UVLO_V ${ }_{\text {SEC }}$ pin voltage in the Typical Performance Characteristics section.

## RIVsec: Open Pin Detection Provides Safety

The LT3753 provides an open-detection safety feature for the $R_{\text {IVSEC }}$ pin. If the $R_{\text {IVSEC }}$ resistor goes open circuit the part immediately stops switching. This prevents the part from running without the volt-second clamp in place.

## APPLICATIONS INFORMATION

Transformer Reset: Active Clamp Technique

The LT3753 includes a $\pm 0.4 \mathrm{~A}$ gate driver at the AOUT pin to allow the use of an active clamp transformer reset technique (Figures 10, 14). The active clamp method improves efficiency and reduces voltage stress on the main power switch, M1. By switching in the active clamp capacitor only when needed, the capacitor does not lose its charge during M1 on-time. By allowing the active clamp capacitor, $\mathrm{C}_{\mathrm{CL}}$, to store the average voltage required to reset the transformer, the main power switch sees lower drain voltage.
In addition, the active clamp drain waveform on M1 (Figure 11) allows a self-driven architecture, whereby the drains of M3 and M4 drive the gates of M4 and M3 respectively, removing the need for a secondary-side synchronous MOSFET driver (Figure 21). In a self-driven architecture, the reset voltage level on M1, Vout level and duty cycle range (governed by system input range) must be considered to ensure the maximum $V_{G S}$ rating of synchronous MOSFETs M3, M4 are not exceeded.

An imbalance of volt-seconds will cause magnetizing current to walk upwards or downwards until the active clamp capacitor is charged to the optimal voltage for proper transformer reset. The voltage rating of the capacitor will depend on whether the active clamp capacitor is actively switched to ground (Figure 10) or actively switched to system input (Figure 14). In an active clamp reset topology, volt-second balance requires:
where:
$V_{\text {IN }}=$ Transformer input supply
$D=\left(V_{\text {OUT }} / V_{\text {IN }}\right) \cdot N=$ switch M1 duty cycle
$V_{\text {OUT }}=$ Output voltage (including the voltage drop contribution of M4 catch diode during M1 off)
$\mathrm{N}=$ Transformer turns ratio $=\mathrm{N}_{\mathrm{P}} / \mathrm{N}_{\mathrm{S}}$
SWP = M1 drain voltage

## LO Side Active Clamp Topology (LT3753)

The steady-state active clamp capacitor voltage, $\mathrm{V}_{\text {CCL }}$, required to reset the transformer in a LO side active clamp topology (Figure 10) can be approximated as the drain-tosource voltage ( $\mathrm{V}_{\mathrm{DS}}$ ) of switch M1, given by:
$V_{\text {CCL }}$ (LO side):
(a) Steady state: $\mathrm{V}_{\mathrm{CCL}}=\mathrm{SWP}=\mathrm{V}_{\mathrm{DS}}$

$$
=\left(\frac{1}{1-\mathrm{D}}\right) \cdot \mathrm{V}_{\mathbb{I N}}=\frac{\mathrm{V}_{\mathbb{N}}{ }^{2}}{\left(\mathrm{~V}_{\text {IN }}-\left(\mathrm{V}_{\text {OUT }} \cdot \mathrm{N}\right)\right)}
$$

(b) Transient:

During load transients, duty cycle and hence $V_{\text {CCL }}$ may increase. Replace $D$ with $D_{\text {VSEC }}$ in the equation above to calculate transient $V_{\text {CCL }}$ values. See the previous section Programming Duty Cycle Clamp-DVSEC. The DVSEC guardrail can be programmed as close as $5 \%$ higher than $D$ but may require a larger margin to improve transient response.

$$
\mathrm{V}_{\text {IN }} \bullet \mathrm{D}=\left(\mathrm{SWP}-\mathrm{V}_{\text {IN }}\right) \bullet(1-\mathrm{D})
$$

Figure 10. LO Side Active Clamp Topology

## APPLICATIONS INFORMATION

As shown in Figure 12, the maximum steady-state value for $V_{\text {CCL }}$ may occur at minimum or maximum input voltage. Hence $\mathrm{V}_{\text {CCL }}$ should be calculated at both input voltage levels and the largest of the two calculations used. M1 drain should be rated for a voltage greater than the above steady-state $\mathrm{V}_{\mathrm{DS}}$ calculation due to tolerances in duty cycle, load transients, voltage ripple on $\mathrm{C}_{\mathrm{CL}}$ and leakage inductance spikes. $\mathrm{C}_{\mathrm{CL}}$ should be rated higher due to the effect of voltage coefficient on capacitance value. A typical choice for $\mathrm{C}_{\mathrm{CL}}$ is a good quality X7R capacitor. M2 should have a $V_{D S}$ rating greater than $V_{C C L}$ since the bottom plate of $\mathrm{C}_{\mathrm{CL}}$ is $-\mathrm{V}_{\text {CCL }}$ during M1 on and M2 off. For high input voltage applications, the limited $V_{\text {DS }}$ rating of available P-channel MOSFETs might require changing from a LO side to HI side active clamp topology.
For the lo side active clamp topology in steady state, during M1 on time, magnetizing current ( $l_{\text {MAG }}$ ) increases from a negative value to a positive value (Figure 11). When M1 turns off, magnetizing current charges SWP untilit reaches $V_{\text {CCL }}$ plus the voltage drop of the M2 body diode. At this

Figure 12. LO Side Vccl vs Duty Cycle (Normalized to 50\% Duty Cycle)

Figure 13. HI Side VccL vs Duty Cycle (Normalized to 50\% Duty Cycle)

Figure 11. Active Clamp Reset: Magnetizing Current and M1 Drain Voltage

Figure 14. HI Side Active Clamp Topology (Using LT3752-1)

## APPLICATIONS INFORMATION

moment the active clamp capacitor is passively switched in to ground (due to the forward conduction of M2 body diode) and the drain voltage increases at a slower rate due to the loading of $\mathrm{C}_{\mathrm{CL}}$. SWP above $\mathrm{V}_{\text {IN }}$ causes $\mathrm{I}_{\mathrm{MAG}}$ to reduce from a positive value towards zero ( dV SWP/dT $=0$ ). As $I_{\text {MAG }}$ becomes negative it begins to discharge the SWP node. Switching in M2 before $\mathrm{I}_{\text {MAG }}$ reverses, actively connects the bottom plate of $\mathrm{C}_{\mathrm{CL}}$ to ground and allows SWP to be discharged slowly. The resulting SWP waveform during M1 off-time appears as a square wave with a superimposed sinusoidal peak representing ripple voltage on $\mathrm{C}_{\mathrm{CL}}$.

The switch M2 experiences near zero voltage switching (ZVS) since only the body diode voltage drop appears across it at switch turn on.

## HI Side Active Clamp Topology (LT3752-1)

For high input voltage applications the $\mathrm{V}_{\mathrm{DS}}$ rating of available P-channel MOSFETs might not be high enough to be used as the active clamp switch in the LO side active clamp topology (Figure 10). An N-channel approach using the HI side active clamp topology (Figure 14) should be used. (The LT3752-1 is ideal for the HI side active clamp topology). This topology requires a gate drive transformer or a simple gate drive opto-coupler to drive the N-channel MOSFET (M2) for switching in the active clamp capacitor from SWP to $\mathrm{V}_{\mathrm{IN}}$. The M1 drain voltage calculation is the same as in the LO side active clamp case and M1 should be rated in a similar manner. The voltage across the clamp capacitor in the HI side architecture, however, is lower by $\mathrm{V}_{\text {IN }}$ since it is referenced to $\mathrm{V}_{\mathrm{IN}}$.

The steady-state active clamp capacitor voltage $\mathrm{V}_{\text {CCL }}$ to reset the transformer in a HI side active clamp topology can be approximated by:
$V_{\text {CCL }}$ (HI side):
(a) Steady state: $\mathrm{V}_{\mathrm{CCL}}=\mathrm{V}_{\text {RESET }}=\mathrm{V}_{\mathrm{DS}}-\mathrm{V}_{\text {IN }}$
$=\left(\frac{D}{1-D}\right) \cdot V_{\text {IN }}=V_{\text {IN }} \bullet V_{\text {OUT }} \cdot \frac{N}{V_{\text {IN }}-\left(V_{\text {OUT }} \bullet N\right)}$

During load transients, duty cycle and hence $V_{\text {CCL }}$ may increase. Replace $D$ with $D_{\text {VSEC }}$ in the equation above to calculate transient $V_{\text {CCL }}$ values. DVSEC guardrail can be programmed as close as $6 \%$ higher than D but may require a larger margin to improve transient response. See the previous section Programming Duty Cycle Clamp-DVSEC.
$\mathrm{C}_{\mathrm{CL}}$ should be rated for a voltage higher than the above steady-state calculation due to tolerances in duty cycle, load transients, voltage ripple on $\mathrm{C}_{\mathrm{CL}}$ and the effect of voltage coefficient on capacitance value. A typical choice for $\mathrm{C}_{\mathrm{CL}}$ is a good quality (X7R) capacitor. When using a gate drive transformer to provide control of the active clamp switch (M2), the external components C1, C2, R1, D1 and T4 are required. T4 size will increase for lower programmed switching frequencies due to a minimum volt-second requirement. Alternatively, a simple gate driver opto-coupler can be used as a switch to control M2, for a smaller solution size.

## Active Clamp Capacitor Value and Voltage Ripple

The active clamp capacitor value should be chosen based on the amount of voltage ripple which can be tolerated by components attached to SWP. Lower $\mathrm{C}_{\mathrm{CL}}$ values will create larger voltage ripple (increased drain voltage for the primary side power MOSFET) but will require less swing in magnetizing current to move the active clamp capacitor during duty cycle changes. Choosing too high a value for the active clamp capacitor (beyond what is needed to keep ripple voltage to an acceptable level) will require unnecessary additional flux swing during transient conditions. For systems with flux swing detection, too high a value for the active clamp capacitor will trigger the detection system early and degrade transient response.

Anotherfactorto consider is the resonance between $\mathrm{C}_{\mathrm{CL}}$ and the magnetizing inductance ( $L_{\text {MAG }}$ ) of the main transformer. An $R C$ snubber $\left(R_{S}, C_{S}\right)$ in parallel with $C_{C L}$ will dampen
(b) Transient:

## APPLICATIONS INFORMATION

the sinusoidal ringing and limit the peak voltages at the primary side MOSFET drain during input/load transients. Check circuit performance to determine if the snubber is required. Component values can be approximated as:
$\mathrm{C}_{\mathrm{CL}}($ active clamp capacitance $)=\frac{10}{\mathrm{~L}_{\mathrm{MAG}}} \cdot\left(\frac{\left(1-\mathrm{D}_{\mathrm{MII}}\right)}{2 \bullet \pi \bullet \mathrm{f}_{\mathrm{OSC}}}\right)^{2}$
where,

$$
\mathrm{D}_{\mathrm{MIN}}=\left(\mathrm{V}_{\text {OUT }} / V_{\text {IN }(\mathrm{MAX})}\right) \cdot N_{\mathrm{P}} / \mathrm{N}_{\mathrm{S}}
$$

and (if needed),

$$
\begin{aligned}
& \mathrm{C}_{S}(\text { snubber capacitance })=6 \cdot \mathrm{C}_{\mathrm{CL}} \\
& \left.\mathrm{R}_{\mathrm{S}}(\text { snubber resistance })=\left(1 /\left(1-\mathrm{D}_{\mathrm{MAX}}\right)\right) \cdot \sqrt{\left(\mathrm{L}_{\mathrm{MAG}} / \mathrm{C}_{\mathrm{CL}}\right.}\right)
\end{aligned}
$$ where,

$$
D_{\text {MAX }}=\left(V_{\text {OUT }} / V_{\text {IN(MIN })}\right) \cdot N_{P} / N_{S}
$$

Check the voltage ripple on SWP during steady-state operation.
$\mathrm{C}_{\mathrm{CL}}$ voltage ripple can be estimated as:
$\mathrm{V}_{\mathrm{CCL}(\mathrm{RIPPLE})}=\mathrm{V}_{\mathrm{CCL}} \cdot(1-\mathrm{D})^{2} /\left(8 \cdot \mathrm{C}_{\mathrm{CL}} \cdot \mathrm{L}_{\mathrm{MAG}} \bullet \mathrm{f}_{\mathrm{OSC}}{ }^{2}\right)$ where,

$$
\begin{aligned}
& D=\left(V_{\text {OUT }} / V_{\text {IN }}\right) \bullet\left(N_{P} / N_{S}\right) \\
& V_{C C L}=V_{I N} /(1-D)(\text { Lo side active clamp topology }) \\
& \left.V_{C C L}=D \cdot V_{\text {IN }} /(1-D) \text { (Hi side active clamp topology }\right)
\end{aligned}
$$

Example : For $\mathrm{V}_{\text {IN }}=36 \mathrm{~V}, \mathrm{~V}_{\text {OUT }}=12 \mathrm{~V}, \mathrm{~N}_{\mathrm{P}} / \mathrm{N}_{\mathrm{S}}=2, \mathrm{~V}_{\mathrm{CCL}}=$ 108 V (Lo side active clamp topology), $\mathrm{C}_{\mathrm{CL}}=22 \mathrm{nF}, \mathrm{L}_{\mathrm{MAG}}$ $=100 \mu \mathrm{H}, \mathrm{f}_{\mathrm{OSC}}=250 \mathrm{kHz}, \mathrm{V}_{\text {CCL }}$ RIPPLE $)=108(0.33)^{2} /(8(22$ - $\left.\left.10^{-9}\right)\left(10^{-4}\right)\left(2.5 \cdot 10^{4}\right)^{2}\right)=10.7 \mathrm{~V}$

The transformer is typically chosen to operate at a maximum flux density that is low enough to avoid excessive core losses. This also allows enough headroom during input and load transients to move the active clamp capacitor at a fast enough rate to keep up with duty cycle changes.

## Active Clamp MOSFET Selection

The selection of active clamp MOSFET is determined by the maximum levels expected for the drain voltage and drain current. The active clamp switch (M2) in a either a lo side or hi side active clamp topology has the same BVdss requirements as the main N-channel power MOSFET. The current requirements are divided into two categories :

## (A) Drain Current

This is typically less than the main N-channel power MOSFET because the active clamp MOSFET sees only magnetizing current, estimated as :

> Peak $I_{\text {MAG }}($ steady state $)=(1 / 2) \cdot\left(\mathrm{N}_{\mathrm{P}} / \mathrm{N}_{\mathrm{S}}\right) \cdot\left(\mathrm{V}_{\text {OUT }} /\right.$ $\left.\mathrm{L}_{\mathrm{MAG}}\right) \cdot\left(1 / \mathrm{f}_{\mathrm{OSC}}\right)$
where,

$$
\mathrm{L}_{\mathrm{MAG}}=\text { main transformer's magnetizing inductance }
$$

Example (LT3752) : For $V_{\text {OUT }}=12 \mathrm{~V}, \mathrm{~N}_{\mathrm{P}} / \mathrm{N}_{\mathrm{S}}=2, \mathrm{f}_{\text {OSC }}=$ 250 kHz and $\mathrm{L}_{\mathrm{MAG}}=100 \mu \mathrm{H}$, Peak $\mathrm{I}_{\mathrm{MAG}}=0.48 \mathrm{~A}$.
This value should be doubled for safety margin due to variations in LMAG , $\mathrm{f}_{\text {OSC }}$ and transient conditions.

## (B) Body Diode Current

The body diode will see reflected output current as a pulse every time the main N-channel power MOSFET turns off. This is due to residual energy stored in the transformer's leakage inductance. The body diode of the active clamp MOSFET should be rated to withstand a forward pulsed current of:

$$
I_{D(\text { MAX })}=\left(N_{S} / N_{P}\right)\left(I_{\text {OUT }}(M A X)+\left(I_{L(R I P P L E)(P-P)} / 2\right)\right)
$$

where,
$\mathrm{L}_{\mathrm{L}(\mathrm{RIPPLE})(\mathrm{P}-\mathrm{P})}=$ output inductor ripple current $=\left(\mathrm{V}_{\text {OUT }} /\right.$
$\left.\left(\mathrm{L}_{\mathrm{OUT}} \bullet \mathrm{f}_{\mathrm{OSC}}\right)\right) \cdot\left(1-\left(\mathrm{V}_{\mathrm{OUT}} / \mathrm{V}_{\text {IN }}\right)\left(\mathrm{N}_{\mathrm{P}} / \mathrm{N}_{\mathrm{S}}\right)\right)$
$I_{\text {OUT(MAX) }}=$ maximum output load current

## APPLICATIONS INFORMATION

## Programming Active Clamp Switch Timing: AOUT to OUT ( $\mathrm{t}_{\mathrm{AO}}$ ) and OUT to AOUT ( $\mathrm{t}_{0 \mathrm{~A}}$ ) Delays

The timings $t_{A 0}$ and $t_{0 A}$ represent the delays betweenAOUT and OUT edges (Figures 1 and 2) and are programmed by a single resistor, $\mathrm{R}_{\text {TAO }}$, connected from analog ground (Pin 18) to the $T_{A O}$ pin. Once $t_{A O}$ is programmed for the reasons given below, $\mathrm{t}_{0 \mathrm{~A}}$ will be automatically generated.

$$
\begin{aligned}
& \text { Front-end timing } \mathrm{t}_{\mathrm{AO}} \text { (M2 off, M1 on) } \\
& =\text { AOUT(edge)-to-OUT(rising) } \\
& =50 \mathrm{~ns}+3.8 \mathrm{~ns} \cdot\left(\frac{\mathrm{R}_{\text {TAO }}}{1 \mathrm{k}}\right), 14.7<\mathrm{R}_{\text {TAO }}<125 \mathrm{k}
\end{aligned}
$$

In order to minimize turn-on transition loss in M1 the drain of M1 should be as low as possible before M1 turns on. To achieve this, AOUT should turn M2 off a delay of $\mathrm{t}_{\mathrm{AO}}$ before OUT turns M1 on. This allows the main transformer's magnetizing current to discharge M1 drain voltage quickly towards $\mathrm{V}_{\text {IN }}$ before M1 turns on.

As SWP falls below $V_{I N}$, however, the rectifying diodes on the secondary side are typically active and clamp the SWP node close to $\mathrm{V}_{\text {IN }}$. If enough leakage inductance exists, however, the clamping action on SWP by the secondary side will be delayed-potentially allowing the drain of M1 to be fully discharged to ground just before M1 turns on. Even with this delay due to the leakage inductance, $L_{\text {MAG }}$ needs to be low enough to allow $I_{\text {MAG }}$ to be negative enough to slew SWP down to ground before M1 turns on. If achievable, M1 will experience zero voltage switching (ZVS) for highest efficiency. As will be seen in a later section entitled Primary-Side Power MOSFET Selection, M1 transition loss is a significant contributor to M1 losses.

Back-end timing $\mathrm{t}_{\mathrm{OA}}$ (M1 off, M2 on) is automatically generated

$$
=\text { OUT(falling)-to-AOUT(edge) }=0.9 \bullet t_{\mathrm{AO}}
$$

$t_{0 A}$ should be checked to ensure M2 is not turned on until M1 and M3 are turned off.

## Programming Synchronous Rectifier Timing: SOUT to OUT ( $\mathrm{t}_{\text {so }}$ ) and OUT to SOUT ( $\mathrm{t}_{\mathrm{os}}$ ) Delays

The LT3753 includes a $\pm 0.4 \mathrm{~A}$ gate driver at the SOUT pin to send a control signal via a pulse transformer to the secondary side of the forward converter for synchronous rectification (see Figures 1 and 2). For the highest efficiency, M4 should be turned on whenever M1 is turned off. This suggests that SOUT should be a non-overlapping signal with OUT with very small non-overlap times. Inherent timing delays, however, which can vary from application to application, can exist between OUT to CSW and between SOUT to CG. Possible shoot-through can occur if both M1 and M4 are on at the same time, resulting in transformer and/or switch damage.

$$
\begin{aligned}
& \text { Front-end timing: } \mathrm{t}_{\mathrm{SO}} \text { (M4 off, M1 on) } \\
& =\mathrm{SOUT} \text { (falling)-to-OUT(rising) delay } \\
& =\mathrm{t}_{\mathrm{SO}}=\mathrm{t}_{\mathrm{AO}}-\mathrm{t}_{\mathrm{AS}} \\
& =3.8 \mathrm{~ns} \bullet\left(\mathrm{R}_{\mathrm{TAS}}-\mathrm{R}_{\text {TAO }}\right)
\end{aligned}
$$

where:

$$
\begin{aligned}
& \mathrm{t}_{\mathrm{AS}}=50 \mathrm{~ns}+\left(3.8 \mathrm{~ns} \bullet \mathrm{R}_{\text {TAS }} / 1 \mathrm{k}\right), 14.7 \mathrm{k}<\mathrm{R}_{\text {TAS }}<125 \mathrm{k}, \\
& \mathrm{t}_{\mathrm{AO}}=50 \mathrm{~ns}+\left(3.8 \mathrm{~ns} \bullet \mathrm{R}_{\text {TAO }} / 1 \mathrm{k}\right), 14.7 \mathrm{k}<\mathrm{R}_{\text {TAO }}<125 \mathrm{k},
\end{aligned}
$$

$t_{S O}$ is defined by resistors $R_{T A S}$ and $R_{T A O}$ connected from analog ground (Pin 18) to their respective pins $\mathrm{T}_{\mathrm{AS}}$ and $\mathrm{T}_{\mathrm{AO}}$. Each of these resistor defines a delay referenced to the AOUT edge at the start of each cycle. $\mathrm{R}_{\text {TAO }}$ was already programmed based on requirements defined in the previous section Programming AOUT to OUT Delay. $\mathrm{R}_{\text {TAS }}$ is then programmed as a delay from AOUT to SOUT to fulfill the equation above for $\mathrm{t}_{\text {So }}$. By choosing $\mathrm{R}_{\text {TAS }}$ less than or greater than $\mathrm{R}_{\mathrm{TAO}}$, the delay between SOUT falling and OUT rising can be programmed as positive or negative. While a positive delay can always be programmed for $\mathrm{t}_{\mathrm{SO}}$, the ability to program a negative delay allows for improved efficiency if OUT(rising)-to-CSW(rising) delay is larger than SOUT(falling)-to-CG(rising) delay.

```
Back-end timing: tos (M1 off, M4 on)
= OUT (falling)-to-SOUT (rising) delay
\(=\mathrm{t}_{\text {OS }}=35 \mathrm{~ns}+\left(2.2 \mathrm{~ns} \bullet \mathrm{R}_{\text {TOS }} / 1 \mathrm{k}\right), 7.32 \mathrm{k}<\mathrm{R}_{\text {TOS }}<249 \mathrm{k}\)
```

## APPLICATIONS INFORMATION

The timing resistor, $\mathrm{R}_{\text {TOS }}$, defines the OUT (falling)-to-SOUT (rising) delay. This pin allows programming of a positive delay, for applications which might have a large inherent delay from OUT fall to SW2 fall.

## Soft-Start (SS1, SS2)

The LT3753 uses SS1 and SS2 pins for softstarting various parameters (Figures 3 and 15). SS1 soft starts internal oscillator frequency and DVSEC (maximum duty cycle clamp). SS2 soft starts COMP pin voltage to control output inductor peak current. Using separate SS1 and SS2 pins allows the soft-start ramp of oscillator frequency and DVSEC to be independent of COMP pin soft-start. Typically SS1 capacitor ( $\mathrm{C}_{S S 1}$ ) is chosen as $0.47 \mu \mathrm{~F}$ and SS 2 capacitor $\left(\mathrm{C}_{S S 2}\right)$ is chosen as $0.1 \mu \mathrm{~F}$. Soft-start charge currents are $11.5 \mu \mathrm{~A}$ for SS 1 and $21 \mu \mathrm{~A}$ for SS 2 .
SS1 is allowed to start charging (soft-start) if all of the following conditions exist (typical values) :
(1) UVLO_V SEC $>1.25 \mathrm{~V}$ : System input not in UVLO
(2) OVLO $<1.215 \mathrm{~V}$ : System input not in OVLO
(3) OC < 96mV: No over current condition
(4) $7 \mathrm{~V}<$ INTV $_{C C}<16 \mathrm{~V}$ : INTV ${ }_{C C}$ valid
(5) $\mathrm{T}_{\mathrm{J}}<165^{\circ} \mathrm{C}$ : Junction temperature valid
(6) $\mathrm{V}_{\text {IN }}>7.75 \mathrm{~V}$ : $\mathrm{V}_{\text {IN }}$ pin valid
$\mathrm{SS} 1=0 \mathrm{~V}$ to 1.25 V (no switching). This is the SS1 range for no switching for the forward converter. SS2 = OV.
SS1 $>1.25 \mathrm{~V}$ allows SS2 to begin charging from 0 V .
$\mathrm{SS} 1=1.25 \mathrm{~V}$ to 2.45 V (soft-start $\mathrm{f}_{\text {OSC }}, \mathrm{D}_{\text {VSEC }}$ ). This is the SS1 range for soft-starting fosc and DVSEC folded back from $22 \%$ to $100 \%$ of their programmed levels. Fold back of $f_{\text {OSC }}$ and $D_{\text {VSEC }}$ reduces effective minimum duty cycle for the primary side MOSFET. This allows inductor current to be controlled at low output voltages during start-up.
SS1 ramp rate is chosen slow enough to ensure fosc and DVSEC foldback lasts long enough for the converter to take control of inductor current at low output voltages. In ad-
dition, slower SS1 ramp rate increases the non-switching period during an output short to ground fault (over current hiccup mode) to reduce average power dissipation (see Hard-Stop).

SS2 = 0 V to 1.6 V (soft-start COMP pin). This is the SS2 range for soft-starting COMP pin from approximately 1 V to 2.6 V .

SS2 ramp rate is chosen fast enough to allow a (slower) soft-start control of COMP pin from a secondary side opto-coupler controller.
SS1 soft-start non-switching period (OV to 1.25 V ) $=1.25 \mathrm{~V} \cdot \mathrm{C}_{S S 1} / 11.5 \mu \mathrm{~A}$

SS1 soft-start fosc, DVSEC period (1.25V to 2.45V) $=1.2 \mathrm{~V} \cdot \mathrm{C}_{\mathrm{SS} 1} / 11.5 \mu \mathrm{~A}$
SS2 soft-start COMP period ( 0 V to 1.6 V ) $=1.6 \mathrm{~V} \cdot \mathrm{C}_{S S 2} / 21 \mu \mathrm{~A}$

## Soft-Stop (SS1)

The LT3753 gradually discharges the SS1 pin (soft-stop) when a system input UVLO occurs or when an external soft-stop shutdown command occurs ( 0.4 V < UVLO_V $\mathrm{V}_{\text {SEC }}$ $<1.25 \mathrm{~V}$ ). During SS1 soft-stop the converter continues to switch, folding back $f_{\text {OSC }}$, DVSEC and COMP pin voltage (Figures 3 and 15). Soft-stop discharge current is $10.5 \mu \mathrm{~A}$ for SS1. Soft-stop provides:
(1) Active control of the secondary winding during output discharge for clean shutdown in self-driven applications.
(2) Controlled discharge of the active clamp capacitor to minimize magnetizing currentswing during restart.
SS1: 2.45V to 1.25 V (soft-stop fosc, D $_{\text {VSEC }}$, COMP). This is the SS1 range for soft-stop folding back of:
(1) $f_{\text {OSC }}$ and $D_{\text {VSEC }}$ from $100 \%$ to $22 \%$ of their programmed levels.
(2)COMP pin ( $100 \%$ to $0 \%$ of commanded peak current).

SS1 soft-stop $\mathrm{f}_{0 S \mathrm{C}}$, $\mathrm{D}_{\text {VSEC }}$, COMP period (2.45V to 1.25 V ) $=1.2 \mathrm{~V} \cdot \mathrm{C}_{S S 1} / 10.5 \mu \mathrm{~A}$

## APPLICATIONS INFORMATION

| HARD STOP (FAULTS) | SOFT-START <br> (WHEN ALL CONDITIONS SATISFIED) | $\begin{aligned} & \text { SOFT-STOP } \\ & (0.4 V<\text { UVLO_V } \end{aligned}$ |
| :---: | :---: | :---: |
| (1) UVLO_V $\mathrm{V}_{\text {SEC }}<0.4 \mathrm{~V}$ | (1) UVLO_V ${ }_{\text {SEC }}>1.25 \mathrm{~V}$ | (1) EXTERNAL SOFT-STOP SHUTDOWN |
| (2) $\mathrm{OVLO}>1.25 \mathrm{~V}$ | (2) $\mathrm{OVLO}<1.215 \mathrm{~V}$ | (2) SYSTEM INPUT UVLO |

| (6) $\mathrm{V}_{\text {IN }}<7.42 \mathrm{~V}$ | (6) $\mathrm{V}_{\text {IN }}>7.75 \mathrm{~V}$ |  |

Figure 15. SS1, SS2 and COMP Pin Voltages During Faults, Soft-Start and Soft-Stop

SS1 < 1.25V. Forward converter stops switching and SS2 pin is discharged to 0 V using 2.8 mA .

SS1 $=1.25 \mathrm{~V}$ to 0V: When SS1 falls below 0.15V the internal SS1 latch is reset. If all faults are removed, SS1 begins charging again. If faults still remain, SS1 discharges to OV.

SS1 soft-stop non-switching period (1.25V to OV) $=1.25 \mathrm{~V} \cdot \mathrm{C}_{S S 1} / 10.5 \mu \mathrm{~A}$

DVSEC rises as system input voltage falls in order to provide a maximum duty cycle guardrail (volt-second clamp). When system input falls below it's UVLO threshold, however, this triggers a soft-stop with the converter continuing to switch. It is important that DVSEC no longer increases even though system input voltage may still be falling. The LT3753 achieves an upper clamp on DVSEC by clamping the minimum level for the $l_{\text {VSEC }}$ pin to 1.25 V . As SS1 pin discharges during soft-stop it folds back DVSEC. As DVSEC falls below the natural duty cycle of the converter, the
converter loop follows DVSEC. If the system input voltage rises (lvsec pin rises) during soft-stop the volt-second clamp circuit further reduces $D_{\text {VSEC. }}$ The I.C. chooses the lowest $D_{\text {VSEC }}$ commanded by either the $l_{\text {VSEC }}$ pin or the SS1 soft-stop function.

## Hard-Stop (SS1, SS2)

Switching immediately stops and both SS1 and SS2 pins are rapidly discharged (Figure 15. Hard-Stop) if any of the following faults occur (typical values):
(1) UVLO_V ${ }_{\text {SEC }}<0.4 \mathrm{~V}$ : Micropower shutdown
(2) OVLO > 1.250V: System input OVLO
(3) OC > 96mV: Over current condition
(4) INTV ${ }_{\text {CC }}<6.8 \mathrm{~V}$ (UVLO), $>16.5 \mathrm{~V}$ (OVLO)
(5) $\mathrm{T}_{J}>170^{\circ} \mathrm{C}$ : Thermal shutdown
(6) $\mathrm{V}_{\text {IN }}<7.42: \mathrm{V}_{\text {IN }}$ pin UVLO

## APPLICATIONS INFORMATION

Switching stops immediately for any of the faults listed above. When SS1 discharges below 0.15 V it begins charging again if all faults have been removed. For an over current fault triggered by OC > 96mV, the disable of switching will cause the OC pin voltage to fall back below 96 mV . This will allow SS1 and SS2 to recharge and eventually attempt switching again. If the over current condition still exists, OC pin will exceed 96 mV again and the discharge/ charge cycle of SS1 and SS2 will repeat in a hiccup mode. The non-switching dead time period during hiccup mode reduces the average power seen by the converter in an over current fault condition. The dead time is dominated by SS1 recharging from 0.15 V to 1.25 V .
Non-switching period in over current (hiccup mode): $=1.1 \mathrm{~V} \cdot \mathrm{C}_{S S 1} / 11.5 \mu \mathrm{~A}$

## OUT, AOUT, SOUT Pulse-Skipping Mode

During load steps, initial soft-start, end of soft-stop or light load operation (if the forward converter is designed to operate in DCM), the loop may require pulse skipping on the OUT pin. This occurs when the COMP pin falls below its switching threshold. If the COMP pin falls below it's switching threshold while OUT is turned on, the LT3753 will immediately turn OUT off ; both AOUT and SOUT will complete their normal signal timings referenced from the OUT falling edge. If the COMP pin remains below it's switching threshold at the start of the next switching cycle, the LT3753 will skip the next OUT pulse and therefore also skip AOUT and SOUT pulses. For AOUT control, this prevents the active clamp capacitor from being accidentally discharged during missing OUT pulses and/or causing reverse saturation of the transformer. For SOUT control, this prevents the secondary side synchronous rectifier controller from incorrectly switching between forward FET and synchronous FET conduction. The LT3753 correctly re-establishes the required AOUT, SOUT control signals if the OUT signal is required for the next cycle.

## AOUT Timeout

During converter start-up in soft-start, the switching frequency and maximum duty cycle clamp D VSEC are both folded back. While this correctly reduces the effective minimum on time of the OUT pin (to allow control of inductor current for very low output voltages during start-up), this means the AOUT pin on time duration can be large. In order to ensure the active clamp switch controlled by AOUT does not stay on too long, the LT3753 has an internal $15 \mu \mathrm{~s}$ timeout to turn off the AOUT signal. This prevents the active clamp capacitor from being connected across the transformer primary winding long enough to create reverse saturation.

## Main Transformer Selection

The selection of the main transformer will depend on the applications requirements : isolation voltage, power level, maximum volt-seconds, turns ratio, componentsize, power losses and switching frequency.
Transformer construction using the planar winding technology is typically chosen for minimizing leakage inductance and reducing component height. Transformer core type is usually a ferrite material for high frequency applications.

Find a family of transformers that meet both the isolation and power level requirements of the application. The next step is to find a transformer within that family which is suitable for the application. The subsequent thought process for the transformer design will include :
(1) Secondary turns $\left(\mathrm{N}_{\mathrm{S}}\right)$, core losses, temperature rise, flux density, switching frequency
(2) Primary turns ( $\mathrm{N}_{\mathrm{P}}$ ), maximum duty cycle and reset voltages
(3) Copper losses

The expression for secondary turns $\left(N_{S}\right)$ is given by,

$$
N_{S}=10^{8} V_{O U T} /\left(f_{O S C} \bullet A_{C} \bullet B_{M}\right)
$$

## APPLICATIONS INFORMATION

where,

$$
\begin{aligned}
& A_{C}=\text { cross-sectional area of the core in } \mathrm{cm}^{2} \\
& B_{M}=\text { maximum } A C \text { flux density desired }
\end{aligned}
$$

For flux density, choose a level which achieves an acceptable level of core loss/temperature rise at a given switching frequency. The transformer data sheet will provide curves of core loss versus flux density at various switching frequencies. The data sheet will also provide temperature rise versus core loss. While choosing a value for BM to avoid excessive core losses will usually allow enough headroom for flux swing during input / load transients, still make sure to stay well below the saturation flux density of the transformer core. If needed, increasing $\mathrm{N}_{S}$ will reduce flux density. After calculating $\mathbb{N}_{S}$, the number of primary turns $\left(\mathrm{N}_{\mathrm{P}}\right)$ can be calculated from,

$$
\left.N_{P}=N_{S} \bullet D_{\text {MAX }} V_{\text {IN(MIN })}\right) V_{\text {OUT }}
$$

where,

$$
\begin{aligned}
& \mathrm{V}_{\text {IN(MIN })}=\text { minimum system input voltage } \\
& \mathrm{D}_{\text {MAX }}=\text { maximum switch duty cycle at } \mathrm{V}_{\text {IN(MIN) }} \text { (typically } \\
& \text { chosen between } 0.6 \text { and } 0.7 \text { ) }
\end{aligned}
$$

At minimum input voltage the converter will run at a maximum duty cycle $\mathrm{D}_{\mathrm{MAX}}$. A higher transformer turns ratio $\left(N_{p} / N_{S}\right)$ will create a higher $\mathrm{D}_{\text {MAX }}$ but it will also require higher voltages at the drain of the primary side switch to reset the transformer (see previous sections Lo side Active Clamp Topology and Hi side Active Clamp Topology). $\mathrm{D}_{\text {MAX }}$ values are typically chosen between 0.6 and 0.7 . Even for a given $D_{\text {MAX }}$ value, the loop must also provide protection against duty cycles that may excessively exceed $\mathrm{D}_{\mathrm{MAX}}$ during transients or faults. While most converters only provide a fixed duty cycle clamp, the LT3753 provides a programmable maximum duty cycle clamp DVSEC that also moves inversely with input voltage.

The resulting function is that of a programmable voltsecond clamp. This allows the user to choose a transformer turns ratio for $\mathrm{D}_{\mathrm{MAX}}$ and then customize a maximum duty cycle clamp $D_{\text {VSEC }}$ above $D_{\text {MAX }}$ for safety. $D_{\text {VSEC }}$ then follows the natural duty cycle of the converter as a safety guardrail (see previous section Programming Duty Cycle Clamp).

After deciding on the particular transformer and turns ratio, the copper losses can then be approximated by,

$$
\mathrm{P}_{\mathrm{CU}}=\mathrm{D} \cdot \mid(\mathrm{Load})_{(\mathrm{MAX})}{ }^{2}\left(\mathrm{R}_{\mathrm{SEC}}+\left(\mathrm{N}_{\mathrm{S}} / \mathrm{N}_{\mathrm{P}}\right)^{2} \mathrm{R}_{\text {PRI }}\right)
$$

where,
$\mathrm{D}=$ switch duty cycle (choose nominal 0.5)
$I(\text { Load })_{(M A X)}=$ maximum load current
$R_{\text {PRI }}=$ primary winding resistance
$R_{\text {SEC }}=$ secondary winding resistance
If there is a large difference between the core losses and the copper losses then the number of secondary turns can be adjusted to achieve a more suitable balance. The number of primary turns should then be recalculated to maintain the desired turns ratio.

## Generating Auxiliary Supplies

In many isolated forward converter applications, an auxiliary bias may be required for the primary-side circuitry and/or the secondary-side circuitry. This bias is required for various reasons: to limit voltages seen by an IC, to improve efficiency, to remove power dissipation from inside an IC and/or to power an IC before target output voltage regulation is achieved ((eg) during $\mathrm{V}_{\text {OUT }}$ start-up).

The best method for generating an auxiliary supply, that is available even for $\mathrm{V}_{\text {OUT }}=0 \mathrm{~V}$, is to have a housekeeping controller integrated into the primary-side IC (Figure 16). This gives the highest efficiency, most cost effective

Figure 16. LT3752 Forward Controller with Additional Integrated Housekeeping Controller for Primary-Side and Secondary-Side Bias

## APPLICATIONS INFORMATION

solution without the need for custom magnetics (limiting selection) or the need for an additional flyback controller IC. The LT3752 is a primary-side forward controller IC with an integrated housekeeping controller and can be easily substituted for the LT3753.

For isolated solutions without a housekeeping controller, there are alternative methods for generating an auxiliary supply for primary-side and secondary-side circuitry. Each method, however, will have trade-offs from the recommended housekeeping controller solution.

## Primary-Side Auxiliary Supply

The LT3753 can operate without a primary-side auxiliary supply since the $\mathrm{V}_{\text {IN }}$ pin has a wide operational range. The current required for all of the gate drivers (OUT, AOUT and SOUT) is supplied by an internal linear regulator connected between $\mathrm{V}_{\mathbb{I N}}$ and $\mathrm{INTV}_{\text {CC }}$. If the efficiency loss and/ or power dissipation and/or current drive capability of that
internal linear regulator is a limiting factor in the forward converter design, then a primary-side bias ( $\mathrm{V}_{\text {AUX1 }}$ ) can be generated to overdrive the INTV ${ }_{C C}$ pin (Figure 17). $\mathrm{V}_{\text {AUX1 }}$ is generated using an extra winding ( $\mathrm{N}_{\text {AUX }}$ ) from the main powertransformer in combination with an inductor (L1) and two Schottky diodes (D1, D2) to generate a buck-derived supply. A 1 mH inductor will usually suffice and should be chosen to handle the maximum supply current required by INTV ${ }_{\text {CC }}$. See also the section INTV ${ }_{c C}$ Regulator Bypassing and Operation in the Applications Information Section.

## Secondary-Side Auxiliary Supply

There are various methods for generating an auxiliary supply to power secondary-side circuitry. The LT8311 synchronous rectifier controller and opto coupler driver IC can be powered in several ways including connection directly to $\mathrm{V}_{\text {OUT }}$. While this is the easiest method, there are various guidelines described in the LT8311 data sheet for powering it's $V_{\text {IN }}$ pin. In most cases a an auxiliary supply is

Figure 17. Primary-Side Bias $\mathrm{V}_{\mathrm{AUX} 1}\left(\mathrm{~N}_{\mathrm{AUX}}, \mathrm{L} 1, \mathrm{D} 1, \mathrm{D} 2\right)$

## APPLICATIONS INFORMATION

the best approach. The following methods can be used to generate a bias ( $\mathrm{V}_{\text {AUX2 }}$ ) to power secondary-side circuitry:
(1) Use a primary-side forward controller with integrated housekeeping controller to generate a secondary-side bias (Figure 16).
(2) Use a buck-derived bias using an extra winding from the main power transformer (similar method as Figure 17, applied to secondary-side circuitry)
(3) Use a custom output inductor with overwinding (Figure 18).
(4) Use a peak-charge circuit (Figures 19 (a), (b), (c)).

Whichever method is used to create the auxiliary supply for secondary-side circuitry, the forward converter should be tested to ensure the auxiliary supply is acceptable for

Figure 18. Output Inductor with Overwinding Supply
voltage range, supply current requirements and behavior during converter power-up/down.

## Primary-Side Power MOSFET Selection

The selection of the primary-side N-channel power MOSFET M1 is determined by the maximum levels expected for the drain voltage and drain current. In addition, the power losses due to conduction losses, gate driver losses and transition losses will lead to a fine tuning of the MOSFET selection. If power losses are high enough to cause an unacceptable temperature rise in the MOSFET then several MOSFETs may be required to be connected in parallel.
The maximum drain voltage expected for the MOSFET M1 follows from the equations previously stated in the active clamp topology sections:

$$
V_{D S}(M 1)=V_{I N}^{2} /\left(V_{\text {IN }}-\left(V_{\text {OUT }} \bullet N\right)\right)
$$

The MOSFET should be selected with a $\mathrm{BV}_{\text {DSS }}$ rating approximately $20 \%$ greater than the above steady state $V_{D S}$ calculation due to tolerances in duty cycle, load transients, voltage ripple on $\mathrm{C}_{\mathrm{CL}}$ and leakage inductance spikes. A MOSFET with the lowest possible voltage rating for the application should be selected to minimize switch on resistance for improved efficiency. In addition, the MOSFET should be selected with the lowest gate charge to further minimize losses.

Figure 19. Peak Charge Supply: (a) Directly from SW, (b) For Low $\mathrm{V}_{\text {OUT }}$ Applications, (c) For High $\mathrm{V}_{\text {OUT }}$ Applications

## APPLICATIONS INFORMATION

MOSFET M1 losses at maximum output current can be approximated as :
$\mathrm{P}_{\mathrm{M} 1}=\mathrm{P}_{\text {conduction }}+\mathrm{P}_{\text {gatedriver }}+\mathrm{P}_{\text {Transition }}$
(i) $P_{\text {CONDUCTION }}=\left(N_{p} / N_{S}\right) \bullet\left(V_{\text {OUT }} / V_{\text {IN }}\right) \bullet\left(N_{S} / N_{P} \bullet\right.$ $\left.I_{\text {OUT(MAX) }}\right)^{2} \cdot \mathrm{R}_{\text {DS(ON) }}$
Note: The on resistance of the MOSFET, $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$, increases with the MOSFET's junction temperature. $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ should therefore be recalculated once junction temperature is known. A final value for $\mathrm{R}_{\mathrm{DS}(\mathrm{ON})}$ and therefore PConduction can be achieved from a few iterations.
(ii) $\mathrm{P}_{\mathrm{GATEDRIVER}}=\left(\mathrm{Q}_{\mathrm{G}} \bullet\right.$ INTV $\left._{\mathrm{CC}} \bullet \mathrm{f}_{\text {OSC }}\right)$ where,
$Q_{G}=$ gate charge $\left(V_{G S}=I N T V_{C C}\right)$
(iii) $\mathrm{P}_{\text {TRANSITION }}=\mathrm{P}_{\text {TURN_OFF }}+\mathrm{P}_{\text {TURN_ON }}(\approx 0$ if ZVS$)$
(a) $\mathrm{P}_{\text {TURN_OFF }}=(1 / 2) \mathrm{I}_{\text {OUT(MAX) }}\left(\mathrm{N}_{\mathrm{S}} / \mathrm{N}_{\mathrm{P}}\right)\left(\mathrm{V}_{\text {IN }} / 1-\mathrm{D}\right)$ $\left(Q_{G D} / I_{G A T E}\right)^{-} \cdot f_{\text {OSC }}$
where,
$Q_{G D}=$ gate to drain charge
$I_{\text {GATE }}=2 A$ source/sink for OUT pin gate driver
(b) $P_{T U R N \_O N}=(1 / 2) I_{O U T(M A X)}\left(N_{S} / N_{P}\right)\left(V_{D S}\right)\left(Q_{G D} / I_{G A T E}\right)$ - fosc
where,
$V_{D S}=\mathrm{M} 1$ drain voltage at the beginning of M 1 turn on
$\mathrm{V}_{\mathrm{DS}}$ typically sits between $\mathrm{V}_{\text {IN }}$ and OV (ZVS)
During programmabletiming $\mathrm{t}_{\mathrm{AD}}$, negative $\mathrm{I}_{\mathrm{MAG}}$ discharges M1 drain SWP towards $V_{\text {IN }}$ (Figure 1). ZVS is achieved if enough leakage inductance exists-to delay the secondary side from clamping M1 drain to $\mathrm{V}_{\text {IN }}$-and if enough energy is stored in $\mathrm{L}_{\text {MAG }}$ to discharge SWP to OV during that delay. (see Programming Active Clamp Switch Timing: AOUT to OUT ( $\mathrm{t}_{\mathrm{A} O}$ )).

## Synchronous Control (SOUT)

The LT3753 uses the SOUT pin to communicate synchronous control information to the secondary side synchronous rectifier controller (Figure 20). The isolating transformer ( $\mathrm{T}_{\text {SYNC }}$ ), coupling capacitor ( $\mathrm{C}_{\text {SYNC }}$ ) and resistive load ( $\mathrm{R}_{\text {SYNC }}$ ) allow the ground referenced SOUT signal to generate positive and negative signals required at the SYNC input of the secondary side synchronous rectifier controller. For the typical LT3753 applications operating with an LT8311, $\mathrm{C}_{\text {SYNC }}$ is $220 \mathrm{pF}, \mathrm{R}_{\text {SYNC }}$ is $560 \Omega$ and $\mathrm{T}_{\text {SYNC }}$ is typically a PULSE PE-68386NL.

Figure 20. SOUT Pulse Transformer

Typically choose $\mathrm{C}_{\text {SYNC }}$ between 220 pF and 1 nF . $\mathrm{R}_{\text {SYNC }}$ should then be chosen to obey:
(1) SOUT $_{\text {MAX }} / 100 \mathrm{~mA} \leq \mathrm{R}_{\text {SYNC }} \leq \sqrt{\left(\mathrm{L}_{\text {MAG }} / \mathrm{C}_{\text {SYNC }}\right)}$
where,

$$
\begin{aligned}
& \text { SOUT }_{\text {MAX }}=I N T V_{C C} \\
& \mathrm{~L}_{\text {MAG }}=\mathrm{T}_{\text {SYNC'S }} \text { magnetizing inductance } \\
& 100 \mathrm{~mA}=\text { SOUT gate driver minimum source current }
\end{aligned}
$$ and

(2) $\mathrm{R}_{\text {SYNC }} \bullet \mathrm{C}_{\text {SYNC }} \geq(-1) \bullet Y /\left(\ln \left(Z / S O U T_{M A X}\right)\right)$

## APPLICATIONS INFORMATION

where,
Y = SYNC minimum pulse duration (50ns; LT8311)
$Z=\mid S Y N C$ level to achieve $\mathrm{Y} \mid( \pm 2 \mathrm{~V}$ : LT8311)
Even though the LT3753 INTV ${ }_{\text {CC }}$ pin is allowed to be over driven by as much as 15.4 V , SOUT MAX level should be designed to not cause $T_{\text {SYNC }}$ output to exceed the maximum ratings of the LT8311's SYNC pin.

Cost/Space reduction: If discontinuous conduction mode (DCM) operation is acceptable at light load, the LT8311 has a preactive mode which controls the synchronous MOSFETS without $T_{S Y N C}, C_{S Y N C}, R_{S Y N C}$ or the LT3753 timing resistors $R_{\text {TAS }}$, $R_{\text {ToS }}$ (leave open).

## Output Inductor Value

The choice of output inductor value LOUT will depend on the amount of allowable ripple current. The inductor ripple current is given by:

$$
\begin{aligned}
& I_{L(R I P P L E)}(P-P) \\
& =\Delta I_{L}=\left(V_{O U T} /\left(L_{\text {OUT }} \cdot f_{O S C}\right)\right) \cdot\left(1-\left(V_{\text {OUT }} / V_{\text {IN }}\right)\left(N_{P} / N_{S}\right)\right)
\end{aligned}
$$

The LT3753 allows very large $\Delta \mathrm{L}_{\mathrm{L}}$ values (low $\mathrm{L}_{0 \text { UT }}$ values) without the worry of insufficient slope compensation-by allowing slope compensation to be programmed with an external resistor in series with the I IENSEP pin (see Current Sensing and Programmable Slope Compensation).
Larger $\Delta \mathrm{l}_{\mathrm{L}}$ will allow lower $\mathrm{L}_{\text {OUT }}$, reducing component size, but will also cause higher output voltage ripple and core losses. For LT3753 applications, $\Delta \mathrm{I}_{\mathrm{L}}$ is typically chosen to be $40 \%$ of $\mathrm{I}_{\text {OUt(max). }}$

## Output Capacitor Selection

The choice of output capacitor value is dependent on output voltage ripple requirements given by :

$$
\Delta \mathrm{V}_{\text {OUT }} \approx \Delta \mathrm{I}_{\mathrm{L}}\left(\mathrm{ESR}+\left(1 /\left(8 \bullet \mathrm{f}_{\mathrm{OSC}} \bullet \mathrm{C}_{\text {OUT }}\right)\right)\right.
$$

where,
$\Delta L_{L}=$ output inductor ripple current $\mathrm{I}_{\mathrm{L}(\mathrm{RIPPLE})(P-P)}$
ESR = effective series resistance (of $\mathrm{C}_{0 \mathrm{UT}}$ )
$f_{\text {OSC }}=$ switching frequency
Cout $=$ output capacitance
This gives:

$$
\mathrm{C}_{\text {OUT }}=\Delta \mathrm{I}_{\mathrm{L}} /\left(8 \bullet \mathrm{f}_{\text {OSC }} \bullet\left(\Delta \mathrm{V}_{\text {OUT }}-\Delta \mathrm{I}_{\mathrm{L}} \bullet \mathrm{ESR}\right)\right)
$$

Typically $\mathrm{C}_{\text {OUT }}$ is made up of a low ESR ceramic capacitor(s) to minimize $\Delta V_{\text {OUT }}$. Additional bulk capacitance is added in the form of electrolytic capacitors to minimize output voltage excursions during load steps.

## Input Capacitor Selection

The active clamp forward converter demands pulses of current from the input due to primary winding current and magnetizing current. The input capacitor is required to provide high frequency filtering to achieve an input voltage as close as possible to a pure DC source with low ripple voltage. For low impedance input sources and medium to low voltage input levels, a simple ceramic capacitor with low ESR should suffice. It should be rated to operate at a worst case RMS input current of :
$I_{\operatorname{CIN}(\mathrm{RMS})}=\left(\mathrm{N}_{\mathrm{S}} / \mathrm{N}_{\mathrm{P}}\right) \mathrm{I}_{\mathrm{OUT}(\mathrm{MAX})} / 2$
A small $1 \mu \mathrm{~F}$ bypass capacitor should also be placed close to the IC between VIN and GND.
As inputvoltage levels increase, any use of bulk capacitance to minimize input ripple can impact on solution size and cost. In addition, inputs with higher source impedance will cause an increase in voltage ripple. In these applications it is recommended to include an LC input filter. The output impedance of the input filter should remain below the negative input impedance of the DC/DC forward converter.

## APPLICATIONS INFORMATION

PCB Layout / Thermal Guidelines
For proper operation, PCB layout must be given special attention. Critical programming signals must be able to co-exist with high dv/dt signals. Compact layout can be achieved but not at the cost of poor thermal management. The following guidelines should be followed to approach optimal performance.

1. Ensure that a local bypass capacitor is used (and placed as close as possible) between $\mathrm{V}_{\mathrm{IN}}$ and GND for the controller IC(s).
2. The critical programming resistors for timing (pins $\mathrm{T}_{\mathrm{AO}}, \mathrm{T}_{\mathrm{AS}}, \mathrm{T}_{\mathrm{OS}}, \mathrm{T}_{\mathrm{BLNK}}$, IVSEC and RT) must use short traces to each pin. Each resistor should also use a short trace to connect to a single ground bus specifically connected to pin 18 of the IC (GND).
3. The current sense resistor for the forward converter must use short Kelvin connections to the ISENSEP and I SENSEN pins.
4. High dv/dt lines should be kept away from all timing resistors, current sense inputs, COMP pin, UVLO_VSEC/ OVLO pins and the FB trace.
5. Gate driver traces (AOUT, SOUT, OUT) should be kept as short as possible.
6. When working with high power components, multiple parallel components are the best method for spreading out power dissipation and minimizing temperature rise. In particular, multiple copper layers connected by vias should be used to sink heat away from each power MOSFET.
7. Keep high switching current PGND paths away from signal ground. Also minimize trace lengths for those high current switching paths to minimize parasitic inductance.
