60 GHz Transmitter (Tx) Waveguide Module

TECHNICAL DATA SHEET PEM001

The PEM001 is a highly integrated millimeter wave transmitter that covers the 60 GHz global unlicensed spectrum allocations packaged in a standard waveguide module. Transmitter architecture is a double conversion, sliding IF with wide bandwidth capability through the upconversion chain from baseband to carrier. The I/Q interface accepts analog baseband signals which provides for flexibility in design and applications. The baseband input optionally supports FSK/MSK modulation for non-coherent applications. The transmitter incorporates a complete waveguide interface with low-loss transition between the chip and the WR15 waveguide port. The integrated package is small and lightweight, with a simple to use multi-pin ST4 connector for power, reference clock, digital control port and baseband signals. Either of two reference clocks can be used for setting 540 MHz or 500 MHz channel spacing.

Features:

- Complete millimeter wave transmitter
- WR-15, UG-385/U flange
- Operates in the 57 to 66 GHz unlicensed band
- 12 dBm typical output power
- Up to 1.8 GHz modulation bandwidth
- I/Q analog baseband interface
- On chip synthesizer covers 57 to 64.8 GHz
- 500 MHz or 540 MHz step size
- 285.714 MHz clock for 500 MHz step size
- 308.572 MHz clock for 540 MHz step size
- Power, control, signals on ST4 connector
- Temperature sensor

Applications

- 802.11ad: 58.32, 60.48, 62.64, 64.80 GHz
- 802.11aj: 59.94, 61.02, 62.10, 63.18 GHz
- Any Channel (500 MHz or 540 MHz) 57-64.8 GHz
- Multi-Gbps Digital Communications
- HD Video Transmission
- Millimeter Wave Radar
- Millimeter Wave Imaging
- Development for 802.11ad and 802.11aj
- ATE Equipment for 60 GHz Manufacturing Test

60 GHz Transmitter (Tx) Waveguide Module

Transmitter Architecture

The PEM001 transmitter uses a double conversion superheterodyne architecture with a sliding IF. The IF frequency is at 1/7 the RF carrier frequency, and the VCO is at 2/7 the RF carrier frequency. The LO is 3x the VCO frequency. The LO and IF are generated from a built-in synthesizer that has a step size at the RF carrier frequency of either 500 MHz or 540 MHz depending upon which reference clock frequency is used. The 540 MHz step size uses a 308.571 MHz reference, and the 500 MHz step uses a 285.714 MHz frequency. The IEEE channels for 802.11ad and 802.11aj are supported when the 540 MHz step size is used. I and Q analog baseband signals are upconverted to the IF frequency at the input mixers. The IF signal is filtered with a variable gain amplifier and filter with approximately 20 dB range, which is then mixed with the LO. A notch filter attenuates the image frequency. The output of the mixer is fed to the PA stage which is coupled to the low-loss waveguide transition. There are optional FSK/MSK baseband data inputs for non-coherent modulation applications. The overall phase noise and I/Q balance specifications are sufficient for up to 16 QAM operation. Configuration and settings are controlled through a digital serial interface port. The block diagram below shows the various stages and circuits in the module.

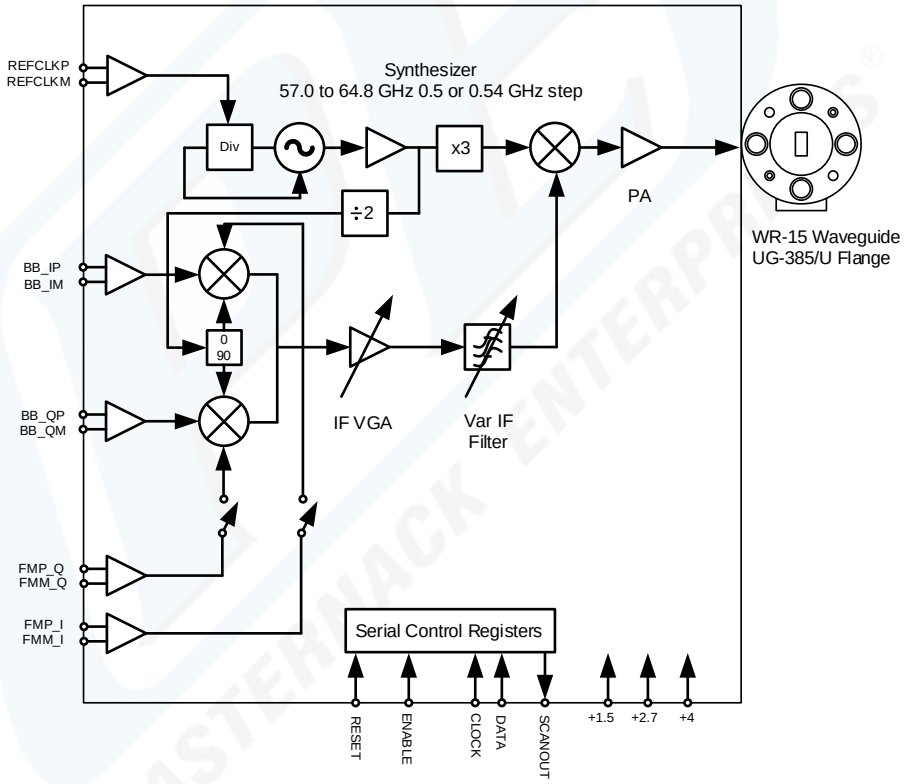

Figure 3 PEM001 Block Diagram

60 GHz Transmitter (Tx) Waveguide Module

Synthesizer Design

The PEM001 transmitter uses a double conversion superheterodyne architecture with a sliding IF. The IF frequency is at 1/7 the RF carrier frequency, and the VCO is at 2/7 the RF carrier frequency. The LO is 3x the VCO frequency.

The tables below show the RF carrier, IF, VCO and LO for the frequency range from 57 GHz to 64.80 GHz at 540 MHz and 500 MHz channel spacing respectively. The reference clock for the synthesizer at 540 MHz spacing is 308.571 MHz; for 500 MHz spacing it is 285.714 MHz. The loop bandwidth of the synthesizer phase lock loop is 200 kHz.

540 MHz Spacing

f_{RF}	IF	VCO	LO
57.24	8.177	16.354	49.063
57.78	8.254	16.509	49.526

60 GHz Transmitter (Tx) Waveguide Module

Digital Control Registers and Serial Interface Protocol - Write Operation

The PEM001 is configured via the serial control port which transfers data synchronously to or from (write or read operation) a register location. Register locations are organized into 16, byte-wide (8-bit) locations. The register locations are written to or read from one byte at a time as shown in Figures 5 and 6 respectively. Figure 5 shows the sequence of the digital control signals for the ENABLE, CLOCK and DATA input pins (ST4 connector, pins 39, 36 and 38 respectively) to write a single byte into the control register. After the ENABLE signal goes low, the first of 18 data bits (bit 0) is placed on the data pin, and 2 ns or more after the DATA signal stabilizes, the CLOCK signal goes high which clocks in data bit 0. The DATA signal must remain stable for at least 2 ns after the rising edge of the CLOCK. The signal levels are 1.5V CMOS, 50 kΩ impedance, with a maximum clock rate of 100 MHz.

A write operation requires an 18 bit field associated with 18 clock pulses as shown in Figure 5. The 18 bit field contains the 8-bit data (LSB is clocked in first), followed by the byte address (BYTE 0 through BYTE 15, 000000 to 001111, LSB first, only 4 of the 6 bits are used with the two MSBs set to 0), the read/write (R/W) bit (write = 1), and the module address which distinguishes between a transmitter module and receiver module (for the V60RXWG3 receiver, RX module = 111).

After clock pulse 17 (18 total pulses), the ENABLE signal is returned to a high state to load the register byte into the module. The CLOCK signal must be stable in the low state at least 2 ns prior to the rising edge of the ENABLE signal.

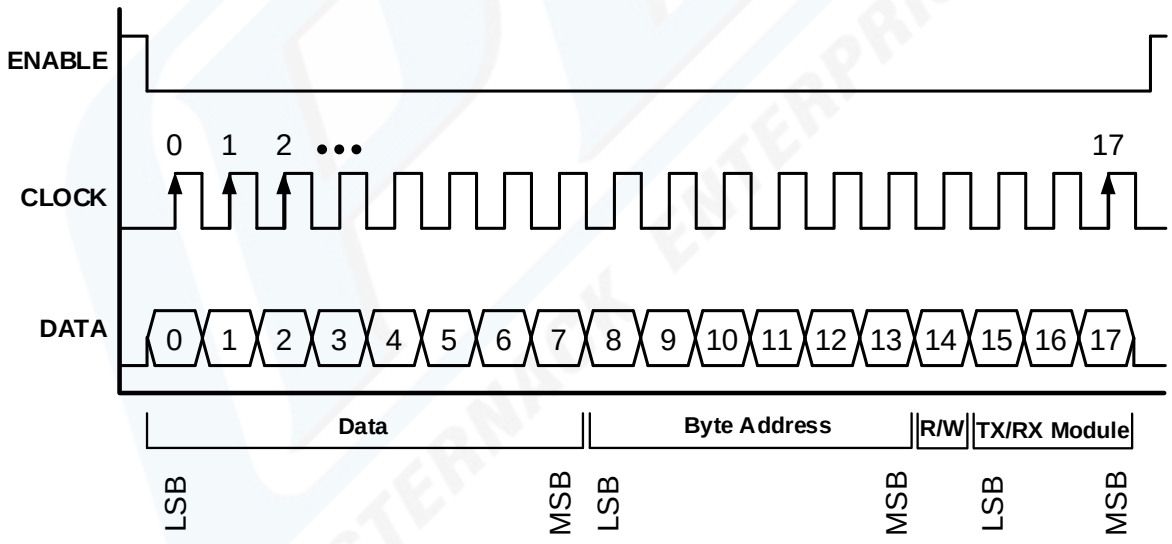

Figure 5 Write Operation Timing Diagram

60 GHz Transmitter (Tx) Waveguide Module

Digital Control Registers and Serial Interface Protocol - Read Operation

Figure 6 shows the sequence of control signals at the ENABLE, CLOCK and DATA pins to read a single byte at a register location. A read operation requires a 27 bit field: The first 18 bits are used to clock in the bits on the DATA input pin. The first 8 bits during a read operation are “don’t care” bits as they are placeholders for the 8-bit byte data which would be present during a write operation. The following 10 bits are composed of the byte address (BYTE 0 through BYTE 15, 000000 to 001111, LSB first, only 4 of the 6 bits are used with the two MSBs set to 0), the read/write (R/W) bit (read = 0), and the module address which distinguishes between a transmitter module and receiver module (for the PEM001 transmitter, TX module = 110, LSB first).

After clock pulse 17 (18 total pulses), the ENABLE signal is returned to a high state while the clock signal is low, then a single clock pulse (pulse 18) is sent during the ENABLE signal high period. The ENABLE signal then returns to the low state while the CLOCK signal is low. At each of the subsequent 8 CLOCK pulses, the 8-bit data from the specified register location is available at the SCANOUT pin, LSB first. Note that the DATA signal must remain in the low state during the period from clock pulse 18 through 26. Following clock pulse 26, the ENABLE signal goes high while the CLOCK signal is low to end the read operation.

60 GHz Transmitter (Tx) Waveguide Module

Table 4.5 Register Byte Functions

Bit	Name	Function
BYTE 12		
7	cpbias_2	Synthesizer charge pump bias; bits <7:5> = 010 for normal operation
6	cpbias_1	
5	cpbias_0	
4	vrsel_3	Synthesizer lock detector window width; bits <4:1> = 1111 for normal operation
3	vrsel_2	
2	vrsel_1	
1	vrsel_0	
0	refselvco	Reserved; bit <0> = 1 for normal operation
BYTE 13		
7	muxref	Reserved; bit <7> = 1 for normal operation
6	div_4	Enable synthesizer divider bit 4; bit <6> = 0 for normal operation
5	en_dc	Synthesizer reference input DC coupling; bit <5> = 0 for normal operation
4	ini	Reserved; bit <4> = 0 for normal operation
3	pd_div_15	Active high to power down 1.5V circuits in synthesizer divider
2	pd_div_27	Active high to power down 2.7V circuits in synthesizer divider
1	pd_qp	Active high to power down synthesizer charge pump
0	pd_vco	Active high to power down synthesizer VCO
BYTE 14		
7	pd_cal	Active high to power down VCO calibration; bit <7> = 0 for normal operation
6	muxout	Multiplexer control for ability to read byte 15; bit <6> = 1 for normal operation
5	pdcalc15	Active high to power down VCO ALC; bit <5> = 1 for normal operation
4	pload	Active high to load adjustment of VCO; bit <4> = 1 for normal operation
3	wide_1	Control for VCO ALC loop; bits <3:2> = 01 for normal operation
2	wide_2	
1	slew_1	Slew rate control of sub-integer N divider; bits <1:0> = 10 for normal operation
0	slew_0

60 GHz Transmitter (Tx) Waveguide Module

Table 4.6 Register Byte Functions

Bit	Name	Function
BYTE 15		
7	comp_p	Synthesizer lock indication (read only): bits <7:6> = 01 locked, = 11 above window, = 00 below window, = 10 disallowed indicating error
6	comp_n	
5	rdacmsb_2	Reserved (read only)
4	rdacmsb_1	
3	rdacmsb_0	
2	rdacmux_0	
1	rdacmux_1	
0	rdacmux_2	

Table 5.1 540 MHz Channels

Channel	Divider	Band[1]	Byte 10	Byte 11
57.24	10101	001	11110001	01010011
57.78	10100	001	11110001	01000011
